For some time negotiations have been in progress for the acquirement by New York and Boston men of the large mining property, situated on Copper Mountain in the vicinity of Princeton, Similkameen, B.C., together with other interests owned by Mr. Emil F. Voigt and associates. The transaction has not yet been completed, but it may be shortly, so the following information is published with a view to conveying an adequate idea of the prospective value of the property and the considerable importance of the projected enterprise which may be expected to lead to the effective development of the property and the utilization of the large mineral resources it is believed to possess. Much of the information has been abstracted from a comprehensive report on the property made by Mr. C. W. Wheelock, of New York City, whose work in this connection extended over a period of three months, from November, 1909, to January, 1910, inclusive:

Location.—Voigt's camp is situated in Similkameen mining division of Yale district, British Columbia. On an air line it is about 120 miles east of Vancouver, 30 miles north of the International Boundary line, about 100 miles west of the Boundary district (where are situated the mines and smelteries of the Granby and British Columbia Copper Companies), and 300 miles north by west of Spokane, Washington, U.S.A.

Similkameen River at this point, flowing towards the north, adjoins some of the property on the west

side of the camp. The nearest town is Princeton, which lies some 10 to 11 miles to the north, and is the present terminal of the Great Northern Railway. From the camp Princeton is reached by a good wagon road, crossing one divide.

Altitude.—The camp is about 2,600 feet above sea level, 800 feet above the smeltery site, and 1,000 feet above the Similkameen River.

Climate.—The climate is good, both summer and winter, permitting outdoor operations to be carried on practically throughout the entire year. The rainfall is moderate and snowfall light.

Transportation.—The Victoria, Vancouver & Eastern Railway (part of the Great Northern Railway system) is extending its line westward, making a direct route from Spokane, Wash., to Vancouver, B.C. The line has been completed to Princeton. Further construction will be proceeded with as rapidly as practicable until the line shall be completed. Previously the district had been without railway communication, making development or construction work economically prohibitive. With the advent of the railway these conditions have been changed.

History of Development.

The development of the mineral deposits of Voigt's camp was commenced 10 or 11 years ago. The country was difficult to prospect owing to its comparative inaccessibility, the steepness of its mountains, and the undergrowth and fallen timber. It was at first believed the mineral veins ran east and west. A considerable amount of clearing, trail-cutting, open-cut, and prospect work was required to reach the various mineral locations and to ascertain the trend of the veins and their probable size. This work has been carefully and intelligently carried out, with the result that the occurrence of enormous veins or mineralized zones has been demonstrated. Approximately $125,000 has been expended in bringing the property to its present condition, besides years of time.

In area and contents the veins would, so far as the development work has proceeded, appear to exceed in both size and value those of the Boundary district, where probably some $8,000,000, including cost of railway construction, had to be expended in order to bring the mining properties to their present profitable basis.

The Voigt properties had been examined on occasions prior to 1907, and are said to have been favourably reported on. The most extensive sampling is said to have been when approximately 100 samples were taken. An average of these samples is stated to have returned 3.10 per cent. copper and $5.15 per ton in gold and silver. While averaging samples is ordinarily very misleading practice, the extensive mineralized area proven in this camp would tend to minimize the errors that ordinarily would occur, relying upon this method. Under the conditions as they exist there, careful work along these lines is the only way that an intelligent approximation of the value can be determined.

At the time the former examinations were made the nearest railways were 75 to 120 miles away, making the handling of an undertaking of this character economically impossible. The general conditions obtaining the past two years (1907-1909), in conjunction with the lack of transportation, have been a bar to further work. Now that the construction and operation of the railway to within six miles of the property have been accomplished, and an extension thereto has been surveyed, this mining enterprise is made, fro transportation standpoint, simple and easy, espe when compared with much of the work that has done in many other places in British Columbi elsewhere.

Area, Topography, Geology, etc.

Property.—Embraced in Voigt's group, in p cally one compact body, are approximately 55 eral claims and fractions; a tract of coal lands; ber tract; a lake, and the land surrounding it, i ing smelter sites; and water-power rights on Si meen River. Of the 55 mineral claims include are Crown-granted, and others are ready for C grant.

Area.—The total area exceeds nine square mile acreage is as under:

Mineral claims	
Lake and surrounding lands controlling further mineral areas	
Coal lands	
Timber lands	
Total area	

Topography and Roads. — The physical conf tion of the country is characteristic of many pa British Columbia. The mountains are steep and ged, frequently cut by precipitous ravines. The of the sides runs from 25 to 30 deg. and in some 35 to 40 degrees.

Road-building, however, is for the most part paratively inexpensive, and the Government is ally ready to bear at least a part of the cost. dition to the excellent wagon road into camp, have been cut in all directions, making easy acc the various parts of the property.

Geology.—Geologically the district has featu unusual interest. Immediately to the north o Voigt property are extensive coal measures, thes tinuing more or less intermittently for a distan 50 or more miles to Nicola district, which has al been entered by the Canadian Pacific Railway. coal is at various places lignite, or bituminou spectively; some of it is coking coal. At G Creek, about 20 miles from Voigt's camp, ther large seams that are claimed to contain an exc quality of coking coal. At Princeton and sou the Voigt properties the coal is a good grade of li

Apparently the entire Voigt country was a time covered by sedimentary rocks, which have uplifted, broken, shattered, eroded, and carried by natural agencies, leaving exposures of mi bearing igneous and altered rocks, and dikes. mineralized area is 2 to 3 miles east and west, to 4 miles north and south. On the extreme e granite; on the west there is an extensive di porphyritic rock, probably rhyolite, about 1,500 in width. Next come the series of veins or miner zones, varying in width from 100 to 800 or 1,000 The western boundary is another porphyritic 1,200 to 1,500 feet wide, which crosses the river ing excellent exposures. Between these two dikes is the mineral belt, containing the several which are separated by smaller dikes, of like s varying in width so far as exposed from 20 to 60

Between the small dikes lie the veins of miner zones, some 26 in number. A striking feature i connection is that all the workings examined, no

ow barren-looking the surface might appear, were l to contain, at very shallow depth, either pro- ced evidence of copper rapidly coming in, or ac- ore of commercial and profitable value. When it nsidered that commercial ore is exposed in veins 00 feet wide and evidence exists of still wider of good ore, the size and great possibilities of ation may be better comprehended.

hile the dikes are apparently all of similar gen- character and origin, the composition of the vein gs varies greatly in character. Roughly, the east of the home camp are heavy in iron. In the al and southern parts more lime appears, princi- in the form of calcite. To the west the ores are silicious. Broadly, the gangue is a highly altered te, or coarse andesite. The metallic contents oc- as a replacement therein, due to the usual causes, mineralized solutions under heat and pressure. metals are principally chalcopyrite, bornite, ar- -pyrite, pyrite, hematite, magnetite, etc., with gold silver in profitable quantities.

Development of Mining Properties.

the aggregate a considerable amount of develop- t work has been done, probably at least $40,000 to 000 worth. When, however, it is remembered that work is scattered over several square miles it will ily be understood that it really amounts to little e than prospecting and does not give any adequate wing commensurate with the conditions at any one e. Such work as has been done is, though, of great e, and will simplify future development. Beside many trenches, and open-cuts, some of them 200 or more long, there are several adits or tunnels n 10 to 110 feet in length, and shafts from 25 to feet in depth. This work is all excellent in its way, wing as it does extensive orebodies, and demon- ting where the succeeding work should be done.

he deepest work in the camp has been done on ms south and southwest of Voigt's, but on the e line of mineralization. A shaft on the Sunset s sunk 190 feet; at 150 feet depth a cross-cut was ven 102 feet, all in ore without reaching the other ll. Diamond-drilling on other claims is reported to ve shown good results, in one instance to 500-600 t depth still showing good ore. This proves that e ore will go to depth. All geological conditions point a similar conclusion. If the veins on the Voigt pro- rty go no deeper than 500 feet there would still be sufficient for a large smelter for many years to me, due to the great width of the veins.

Sampling.—Technically, no fair estimate could be ade of developed tonnage. Considerable amounts of e of commercial value, however, are exposed. The mpling, therefore, had to be done, not with a view establishing tonnage, but rather to ascertain as far possible the ore value in the bodies already demon- rated. Samples were taken along a distance of out two-and-a-half miles. (Note.—Full details are ven in the report of results of assays of 27 samples, d of check assays). Eliminating four surfaces and ve high-grade samples, and taking the remainder as presentative of known orebodies of large dimen- ons. they show an average content of copper, 2.038 er cent., and gold and silver $0.968 per ton (calcu- ting silver at 50 cents per oz.). The veins from which he five high-grade samples were taken (not included the foregoing average value), will undoubtedly pro- uce a sufficient tonnage to substantially increase the average value, in both copper and gold. However, taking the average as given above and estimating copper at 12 cents per pound, it gives a gross value of $5.84 per ton. From a tonnage of this value sufficient to supply a 1,500-ton smelter, the following results may, with good management, safely be expected, if, as is estimated. 85 per cent. of the copper and 90 per cent. of the gold and silver be recovered, and total costs be $3.50 per ton.

	Per Ton.		
Copper at	Net recovery	Net profit.	Net per day
10 cents	$4.332	$0.832	$1248
11 cents	2.678	1.178	1767
12 cents	5.024	1.524	2286
13 cents	5.370	1.870	2805
14 cents	5.716	2.216	3324
15 cents	6.062	2.562	3843

For a year of 330 operating days the net profits would be, with copper at 10 cents, $411,840; at 11 cents, $583,110; at 12 cents, $754,380; at 13 cents, $925,650; at 14 cents, $1,096,920; at 15 cents, $1,268,190.

Should ore be developed in bodies as large as surface exposures would indicate them to be, there is no reason why, under good management, costs should not be made equally as low as those of the Boundary district, especially as several items of cost—power, coke transportation charges, and better local conditions—would be distinctly in favour of the Voigt property.

Summary of Other Matters.

Mr. Wheelock's report goes into much more detail than that already given, and, too, in regard to other matters not here quoted, and some of the latter will be very briefly summarized.

Analyses indicate that with the addition of a small percentage of lime the ores will work easily and directly in a blast furnace. There are two available lime deposits close at hand. Cost of coke from Granite Creek or Nicola will probably be not more than $5.50 per ton, which would be $1 less than cost of Crow's Nest coke to Boundary smelters. There are several sites, near Smelter Lake and but a short distance from the site, for a hydro-electric power station, suitable for a smeltery.

In further developing the property, the topography of the country affords favourable conditions, as depths of from 600 to 1,400 feet could be gained by driving adits or tunnels 2,000 to 6,000 feet. Nearly all work would be by adits largely in ore, and all ore be handled by gravity. Local conditions are such that beyond an electric tramway for conveying ore from mine to smeltery, the ore could be handled automatically by gravity and at low cost.

Ample hydro-electric power for all mine, smeltery, tramway, and lighting purposes can be developed at a reasonable cost for installation of plant, on Similkameen River. There is an excellent site for a dam, and 5,000 h.p. could be developed.

There is estimated to be about 7,000 feet per acre of timber — red fir, some pine, etc. — which would give cheap timber for mining and construction uses for years.

The coal lands have not yet been developed, so their value is unknown.

A careful study of the property and conditions leads to the opinion that with proper development and management it should become a large copper mine, and that copper could be produced at eight cents per lb., or possibly less.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Dominion Coal Output.

The production for the first half of July was uniformly good, being at the rate of 370,000 tons for the month. While the outputs this season are not actually as high as in some former years, their steadiness is remarkable, and the breaks caused by the pay-days are not so marked as in some previons seasons.

The new collieries at Lingan are beginning to count materially in the outpnt figures. No. 14 Colliery is now producing over 1,000 tons daily, and the output for one day from the four new collieries is now nearly 2,500 tons, about one-sixth of the entire output.

The branch line to the Birch Grove Colliery is under construction, and will be completed during the autumn. This mine is producing about 1,500 tons per month at the present time. It is now known as Dominion No. 21, and is the first of a new series of mine numbers.

The North Atlantic Collieries at Port Morien were advertised to be sold at auction by the sheriff on the 13th July, but the sale has now been postponed until the 29th September. About 150 tons a day is being mined, and the development work is being kept up.

The Springhill Collieries have been constitnted into a superintendence district under the scheme of organization used by the Dominion Coal Company, and will be known in future as "Dominion Coal Company District No. 5, Springhill." The output is rapidly increasing, and from the two slopes is now 1,200 tons daily.

The examinations for provincial certificates of competency for mine officials were largely attended. For managers' certificates 34 candidates presented themselves, of whom 16 were successful. For underground managers' papers 15 candidates were successful out of 31 applicants. For overmen's papers 21 passed out of 31 who sat for the examination. The rapid opening up of new collieries in Cape Breton has necessitated the appointing of many new managers, and the large number of aspirants for certificates of competency is evidence of the growing importance of the industry. When the Dominion Coal Company was incorporated in 1893 it operated only four collieries, namely, Dominion No. 1, Caledonia (No. 4), Reserve (No. 5), and International (No. 8). To-day this company has no less than 15 collieries, for each of which a manager is required. Cape Breton men will also play a large part in the opening up of the coalfields of the West, only now properly commencing. It is a very short-sighted national policy which requires miners to obtain certificates of competency for every Province of the Dominion in which they may elect to exercise their profession.

The Commissioner of Mines for Nova Scotia has engaged Mr. A. L. McCallum, of Halifax, to visit the coal mines of the Province and take barometric and thermometer readings underground, ascertain the humidity of the ventilating current and its velocity, and to take observations of the amount of dust in suspension in the mine air.

The British Home Office recently passed an order directing that a sufficient number of canaries, linnets, or other small birds, should be kept near the pit-top at every British colliery, in readiness for the use of rescue parties should the necessity for them arise. It has long been the custom for parties entering a mine after an explosion or fire to carry with them a small bird in a cage, and to judge by its behaviour whether or not the air was poisonous. The chief danger to such parties arises, of course, from carbon-monoxide, which cannot be detected by the ordinary evidence of the senses, as it is odourless and will support combustion. In the presence of carbon-monoxide a canary or linnet will fall from its perch long before men are affected, and by so doing give the signal for retreat. The Dominion Coal Company has obtained a number of canaries that are to be kept at the Central Rescue Station at No. 2 Colliery.

ONTARIO.

Porcupine, Swastika, and Gowganda.

For some weeks to come public interest will be divided almost entirely from the activity of the mines to the reconstruction of the camp as a community. A drenching rain is now falling and the great uneasiness that has prevailed everywhere owing to the materials for another awful blaze is disappearing, and every man is getting extremely busy in his business. It is certain that the disaster has taught the miners of Northern Ontario a lesson that they will never forget. The fire here from Cochrane and north of the Transcontinental to Sudbury was not merely a bush fire in the ordinary acceptation of the term, but a cyclone fanning all the combustible materials in the virgin forest till it was like a blast furnace. The flames did not creep along the ground, but the carbon dust driven on the wings of the wind in the air roared out in great masses of detached flames. Good clearings were of no avail. At the Dome Mines, where 160 acres were swept clear of trees, the air was on fire. Flames shot out of the various buildings at once, and men fighting the blaze were at once surrounded and ringed in. Three-quarters of the loss of life was due directly to the attempt to beat back the waves of flame and smoke, and never again in the north country will it be possible to get a mining force to combat the fire unless they have some place of retreat.

This very matter is under consideration at the present time. Mr. Ambrose Monell, of the Dome Mines, now personally superintending the construction of the Dome Mines, is possibly responsible for the suggestion. He maintains that a root house were provided at every mine where the men could retreat under circumstances such as occurred last week, not only would lives be saved but the men, knowing they had a safe retreat, would defend the property till the last moment. To be effective, however, every property and every prospect in northern Ontario so surrounded by the bush must be obliged to have this retreat where water should always be kept and proper ventilation provided. It should come under the supervision of the Inspector of Mines, and be as essentially a part of the equipment as a proper hoist and safety appliance on the cage. After such an awful lesson it is not likely that Porcupine mines will take any risks, but throughout the north as fresh camps spring up, the materials for further tragedies are provided unless some such cyclone cellar is provided.

At the Dome Mines it is hoped that the compressor will be running again in a month's time, and the perfect organization which the Canadian Copper Company has at its call is being invoked to repair the damage as quickly as possible. Of the machinery, so intense was the heat, very little will be saved; but the foundations of the big mill appear to be sound. It is now expected that the mill will be constructed and ready to drop stamps by Christmas. While the design of the mill will be identical with that destroyed, the construction of the building will be entirely of concrete, steel and brick, so that in this case the Dome men will have a haven of refuge in the event should there again be such a whirlwind of fire as swept over this country. In the eastern and southern portions of the Dome further bodies of quartz and schist have been opened up by the fire, and a gang of prospectors under Mr. Brand, former manager of the Standard Porcupine, will be put at work prospecting and sampling, while as soon as the compressor is working, test pits will be sunk. It is also desired to attack the 300-foot level in the three Dome shafts as soon as possible.

It is safe to say that no miner in northern Ontario will ever take shelter in a shaft again in case of fire. In the holoc

of July 11, not one man who went down a shaft and stayed escaped suffocation. In the Pearl Lake area, with the ion of the Vipond, mining activity has not been inter- one day. Until the T. & N. O. line is extended to Miller the Hollinger is content to prospect and sample and e plans for the new and larger mill. When better trans- ion is provided the machinery is to be hauled in.

McIntyre has had a series of very rich and spectacular eries, both on the surface and underground. In a drift 100-foot the quartz veiu sunk upon is now showing re- ble ore in both faces.

Uder the control of the Drummonds the Jupiter is now as- of the systematic mining that its surface showings de- serv News has just been received that at sixteen feet from the haft at the 100-foot level driftiug north the vein has been ut. It exhibits four feet of as remarkable ore as on the sur- face and there is now very little possibility that the option will not be taken up.

Armstrong-Booth, in which Mr. E. P. Earle, of the Nipis- ng Mr. Frank Armstrong, of New York, and Mr. David sn, of Toronto, are interested, has made remarkable pro- re: It definitely has the extension of the Jupiter on f its claims and good assays have been obtained both e surface and with the diamond drill at 180 feet. On aim on the edge of Pearl Lake, near the No. 1 camp of ewick-Moreing, the four to six-foot lead of quartz is rich sible gold. Near its own camp, just south of the Rea, atest discovery has been made. The vein is much broken the surface but yields very rich specimens and the dirt ins so much gold that a rocker has been installed to pan

At the north end of Porcupine Lake, the Porcupine Lake Mines will install a four to six drill compressor as soon e machinery can be rushed in. While there is very little le gold in the large ore body uearly every specimen of tz panned gives a rich tail aud the assays are always factory.

e fire has aggravated the freight congestion at Porcupine at the present time 150 cars are on the road to the camp een North Bay and Golden City. A siding to contain cars is to be constructed, and even this accommodation be strained, so large is the amount of business that will one before the snow falls. As soon as lumber can be ob- d South Porcupine will be rebuilt, and before the first the settlement will probably be almost as big as ever.

THE FATALITIES.

ereunder is given a list, corrected up to date of going to s, of the Porcupine fire casualties. It is possible, but uot able, that this list may receive additions. Since the res- parties, sent out to determine the fate of isolated pros- ors, found no one in need of assistance, it is hoped that tale of deaths is complete. The excitement caused by the catastrophe news is, perhaps, sufficient excuse for the s exaggerations that appeared in the newspapers.

Death List.

ules Metayer (Le Bretton), telegraph French Consul at treal; buried northeast side lake.

ndre Le Roux, telegraph to manager Metropole Hotel, Mont- , was waiter there; effects giveu to wife here; buried Ed- ds Point.

rpila Mondoux, Cobalt, telegraph to Lang McNabb ad- ed; age 50; recovered.

harles E. Adams, Phoenixville, Pa.; relatives advised; age shipped by friends to McNabb.

William Taylor, Pearl Lake; telegraph to wife and ee children in Reading, England (wired Lord Strathcona); ried at Pearl Lake.

R. A. Dwyer; Lawton wired brother in Butte, Montana; found and buried on Uuited Porc. Gold Mines property.

Jos. Flynn, Bracebridge, Ont.; found and buried on United Porc. Gold Mines property.

Audy Youill, superintendent, Toronto; found and buried on Uuited Porc. Gold Miues property.

Joe Fletcher, Cockermouth, Cumberland Co., England; sister, Mrs. B. Allen (same address); found and buried ou United Porc. Gold Mines property.

One unidentified, found and buried on United Porc. Gold Mines property.

Pat Dwyer.

Wm. Moore, Cobalt; age 35; shipped.

Melvin Strain, Porcupine; relatives here; recovered.

Nathan Haas, Spokane, Wash.; brother, Ed Haas, Houghton, Mich., here; shipped.

Stan. Nicholson, Guelph; wife in Guelph advised; age 28; shipped.

Wm. Gore; wife here; age 43; buried.

T. R. Geddes; age 54; buried on Foley-O'Brien.

Mack Smith, New Liskeard; relatives advised; buried on Foley-O'Brien.

Thos. Bodin, man of same name living; buried on Foley-O'Brien.

Capt. Thos. Duubar, of Kennedy & Dunbar, Pembroke; buried on Foley-O'Brien.

Harry Hardy, Dome Miues; telegraph P. M. Bath, England, assayer; boarded at southeast coruer Adelaide and Peter Sts., Toronto (wired Lord Strathcona); buried here.

Fritz Manse, Dome Mines; Melbourne, Australia; aged 18; Buried at Dome.

John Whatmaugh, Dome Mines; Toronto student; age 22; buried at Dome.

Thos. John King, Dome Mines; Copper Cliff; age 55; buried at Dome.

Charles Jackson, Dome Mines; coloured; Pittsburg, Pa.; buried at Dome.

Archie Johnston, Dome Mines; Sudbury, Ont.; buried at Dome.

Leo H. Sulman, Dome Miues; Loudon, Eng.; assayer; body shipped.

Stanley Fitzmaage, Dome Mines; Melbourne; age 27; buried.

Arta Alhod, Dome Mines; Kelso; died in transit.

Didelo Diepro, Dome Mines; died in Liskeard hospital.

Robert Weiss, West Dome; Butte, Mont.; age 60; buried.

Mrs. Robert Weiss, West Dome; Butte, Mont.; buried.

Weiss' child, West Dome; Butte, Mont.; buried.

James Reunie, West Dome; Edinburgh, Scot.; buried.

R. J. Welch, West Dome; Cache Bay, Ont.; buried.

John McLaughlin, West Dome; Venisoti, Ont.; shipped.

Wm. King, West Dome; Los Angeles, Cal.; buried.

Angus McDonald, West Dome; Turner Street, Ottawa; buried.

Mr. and Mrs. A. E. Burt, West Dome; Cobalt; buried.

John Destern, West Dome; Toronto student; buried.

Mr. and Mrs. D. M. Macqueen, West Dome; Kippen, Scot.; buried.

John Wall, West Dome; buried.

Harry Brookins, West Dome; wife here; buried.

John Saunch, West Dome; buried.

Hugh McLeod, West Dome; Glencoe Mills, Cape Breton; buried.

Lester Heuninger, West Dome; buried.

J. W. Cranshaw, West Dome; Phoenix, Ariz.; buried.

Wm. McLean, West Dome; buried.

J. Paulin, West Dome; Montcerf, Ont.; buried.

Unidentified man, West Dome; buried.

J. Orr, West Dome; buried.

W. Beeita, West Dome; buried.

A. J. Ryan, West Dome; notified T. A. Dobbins, Manhattan Drilling Company, 50 Church St., New York; buried.

Victor Puera, West Dome; buried.

E. Sherrien, Ottawa; died in transit.

Hugh Meehan, Sudbury; brother notified at Sudbury; buried half mile south Goose Lake, in Shaw.

John McDonald, Eaginville; wife, same address, notified; brother in Deloro; buried half mile south Goose Lake, in Shaw.

Mike Johnson, found on Trout Creek, Nighthawk district; supposed to have committed suicide.

Marshall Morrison, Haileybury; found at corner Tisdale, Whitney, Shaw, and Deloro.

Fred Herbert, England; found at corner Tisdale, Whitney, Shaw, and Deloro.

Edward Cullen, Haileybury; Eagan claims.

Ormond Butler, Tangier, southeast Shaw.

Thomas Cooper, died New Liskeard.

John Bowers, died New Liskeard.

Pretro, Depaoli, died Copper Cliff.

John Bilo, died New Liskeard.

Arthur Hale, died Copper Cliff.

REPORTED MISSING.

Those missing, and where supposed to have been.

George Snowden Andrews; Pigeon Rapids, Mattagami.

Malcolm Black; Kamescotia.

William Black; Kamescotia.

Frank Byron.

Oscar Butler, of Tangier; found dead.

Harry Bruce.

Desire Bourdon.

— Barrette.

Tom Bascom; Bristol.

Sam Brown; working on Rowe claims, Langmuir.

Herbert Bentley; Price Township.

Roy Brady and companion, of Toronto; probably camping on Claim 3103-P, Shaw Township.

Fred Bidgood; advise John Bidgood, King Edward Hotel, Sudbury.

J. Coyne; Powell claims, Deloro.

Edward Cullen; 2021 Broadway, New York City; found dead.

T. Condil, Haileybury.

Thos. Croon; working on Rowe claims, Langmuir.

Fred Clarke, Brockville.

Russell Dale.

Harry Darce, or Dance; working for Martin Vair.

John S. Dekker, Porcupine; Cripple Creek.

Joe. Dudley; Price.

Joradius Darling; Telegram Merrill.

— Dalby; South Langmuir.

A. W. Dexter, Folkestone, Kent, England; Powell claims, Deloro.

Bill O'Flynn.

Flanerty Crawford; West Dome.

C. S. Feslier, Butte, Montana.

T. Gravelle; Whitesides-Cripple Creek.

Howard Genchon; wire Car Inspector C. P. R., Alex Mac.

Fred Herbert, found dead; 2 miles west of Shaw, near Powell claims, Deloro.

Henry Robert; Pearl Lake

T. W. C. Hutchins; Cripple Creek with Fred Hamilton.

Fred Hamilton; Cripple Creek.

Sylvia Hortell, of Sudbury.

O. Jelly.

Sam Jeveraux, Cobalt: Cripple Creek.

James Lefranier, Quebec.

— Lacroix, Haileybury.

J. J. Shea; Eldorado.

Ed. Sinclair, of Sault Ste. Marie, Mich; went to Cripple Creek.

Willie Thackery.

William Anthony Thompson.

C. Villeyea.

Chas. Villagracia; Powell claims, Deloro.

Cobalt.

The striking of good ore in the No. 23 shaft of the Nipissing opens up yet another section of this great property for profitable mining. A shaft was sunk to 100 feet and the ore drifted upon for some distance before good ore was struck. Such progress has been made at the new mill that more than half of the high grade ore now goes out in the shape of bullion.

At La Rose the two subsidiary properties of the La Rose and the Princess are providing more than half the output. The Princess now has a vein 120 feet long, resembling the McKinley-Darragh veins in character, namely rich stringers in an ore body twelve feet wide in some places. At the La Rose good ore is being taken out of the roof of No. 8, and development has now proceeded to such a point that No. 8 and No. 9 veins should soon be cut at the 200-foot level.

So far development at the 575-foot level of the Temiskaming has proven disappointing. While several rich patches of ore have been encountered no definite ore body has been located.

BRITISH COLUMBIA.

Last field-work season Mr. John A. Allan, of the Geological Survey of Canada, commenced a survey for a sheet that will include the Ice River district and an area about Field, B.C. The following are excerpts from his preliminary report, as printed in the "Summary Report" for 1910: "July and August were spent in the Ice River area proper, which is important because it contains one of the very few igneous intrusive masses which are at present known in the whole of the Rocky Mountain belt. This igneous mass is of the alkaline type, and contains sodalite deposits. This mineral has a limited

occurrence in Canada. . . . This district is especially known because of the somewhat rare occurrence of sodalite, which is found in the intrusive mass. This beautiful blue mineral has attracted many tourists into the valley, who wished to obtain specimens of this decorative stone.'' Following a further description of the occurrence of sodalite, Mr. Allan concludes his report thus: ''Before the material can be considered of economic importance, it will be necessary to find out its extent, which can only be ascertained by development of the property. This occurrence is worthy of consideration, as the material can be inexpensively worked, and the transportation problem is not a difficult one.''

Southeast Kootenay.—While occasional mention has been made in mining journals of the great size of the deposit of coal the Corbin Coal & Coke Company, of Spokane, Washington, has during the last three years been engaged in opening in the southern part of the Crow's Nest district, no conception of its astonishingly large proportions has been generally obtained. One principal reason for the comparative lack of information relative to this altogether unusual occurrence of coal is the fact that the Corbin company has persistently avoided publicity in this connection. Nevertheless, it is a fact that a phenomenally large body of coal is being explored, though as yet without any clear idea of how big it really it, development work not yet having reached the limits of the coal. From Mr. E. J. Roberts, managing director of the company, particulars of operations were recently obtained. Summarizing the information then supplied, the following brief account of the present situation at the company's mines is submitted: The mine that has during the last two years been producing coal is at a comparatively low elevation—about 500 feet above the tippie. The main entry there has been driven approximately 2,000 feet and the coal deposit found to be at its widest part on this level fully 300 feet in width. Beyond this wide part it has narrowed considerably, what appears to be a large point of rock having come into the coal. Development work is not being continued here, however, for there is so much coal available for mining that the driving of additional length of entry would only involve maintenance costs that are quite unnecessary so long as the further opening of the coal body in that part of the mine is not required to keep up the supply for shipment. At an elevation of about 1,200 feet above the main entry, on Coal Mountain, there occurs what is known locally as the ''upper big showing.'' About 400 feet lower down the mountain, or 800 feet above the main tunnel, there is another big outcrop of coal, known as the ''lower big showing.'' During the last six months these ''big showings'' have been partially prospected. An underground cross-cut proves the coal of the upper showing to be 96 feet in width where prospected by this working. Analyses of every 10 feet of coal give the following average percentages for 12 tests: Moisture, 0.87; volatile combustible, 18.47; fixed carbon, 67.86; ash, 12.80. The highest results were from the sample taken from the last 9 feet of coal cut in this tunnel, namely: Moisture, 0.45; volatile combustible, 15.70; fixed carbon, 77.40; ash, 6.45. The lower big showing has been cross-cut by an adit which at 370 feet from its portal entered slate rock. Analyses, 37 in number, of every 10 feet of coal passed through, gave the following general average percentages: Moisture, 0.73; volatile combustible, 20.03; fixed carbon, 64.25; ash, 15.00. The highest results were from coal cut between 20 and 30 feet in from the portal of the adit. They were as follows: Moisture, 0.60; volatile combustible, 22.49; fixed carbon, 68.31; ash, 8.60. This lower showing of coal has also been cut in pits sunk through the surface wash depths varying down to 15 feet, and the vertical depth of the underground working where it entered the slate is approximately 200 feet below the coal cropping in the pit immediately above it. This enormous deposit of coal continues to be a problem to those engaged in exploring it, and much more development work will be necessary ere it will be understood. Meanwhile, a commencement has been made to hydraulic the surface wash off it.

Tulameen.—The Similkameen Star says: ''Chas. Camsell has taken about half a ton of alluvial from the Tulameen diamond belt to be assayed at Ottawa.'' This is probably a somewhat inaccurate statement, but it is known that it was Mr. Camsell's intention to spend the latter part of June in searching for diamonds in the placer deposits in the vicinity of Olivine Mountain, from the peridotite of which mountain were last year taken the samples of chromite in which Mr. R. A. A. Johnston, mineralogist of the Geological Survey of Canada, when determining the nature of the chromium minerals, secured some insoluble crystals which, on subjecting them to further tests, he found to be diamonds. In his report on last year's field work, printed in the 1910 ''Summary Report'' of the Survey, Mr. Camsell observed: ''Placer deposits have been found in the streams which drain the peridotite, and in these it is to be expected that diamonds comparable in size and quality with those obtained in the laboratory will be found. These deposits may also contain stones of greater size, but in the placer mining for gold and platinum which has been carried on in these streams for a number of years, although stones of commercial size on the sluice boxes should have attracted the attention of miners, the discovery of a diamond has not yet been recorded.'' The mineralogist of the Survey will closely examine all material that shall be sent to him from the Tulameen placer deposits. It is hoped that later in the season some black sand saved from placer mining operations, will be available for close examination for evidences of the occurrence of diamonds in the drift.

General News.—Six more men have been sent from Alberni to the Big Interior copper mine, Great Central Lake district, Vancouver Island. These will increase the working force to 14. The Alberni News says that 40 to 50 men will be employed all summer.

The next general meeting of the Western Branch of the Canadian Mining Institute will be held at New Denver, Slocan Lake. The date has not yet been definitely determined, but it will be during either the second or third week in September. It is intended to give especial attention to the reading and discussion of papers on subjects connected with mining in Slocan district.

From Barkerville comes information that after one of the deepest snowfalls experienced in Cariboo district for years, the spring was late and backward, so much time was lost in the early part of the hydraulicking season. However, when the letter containing this news was written, work was in full swing, the only fear being that warm rains and hot weather would melt the snow very quickly. Fortunately, though, a cool change had been experienced, so that fears of a short season were lessened for the time. The opening of some new placer mines was contemplated, but men were scarce, so that it was not then practicable to put in the requisite hydraulicking equipment and get water on the ground. Several parties had been trying to arrange for opening quartz properties, but it did not seem likely that much money would be spent this year in systematic and well-directed lode mining.

Mr. S. F. Griswold, managing director of the Inland Empire Mining and Milling Company, owning a property situated on Grenville Mountain, in the extreme western portion of the Rossland district, was recently reported to have said, for publication in Spokane, Washington; ''We are installing a 10-stamp mill, supplied by the United Iron Works of Spokane, on the Inland Empire Company's property. The mine is developed by a shaft to 300 feet, with 400 feet of drifting on three levels.

These workings show a 14-foot ledge, carrying free-milling ore, which we believe will average $30 a ton. The shareholders of the company, with the exception of my son and myself, are all Walla Walla (Washington) people. They have been interested in the property and quietly developing it for seven or eight years. The company is capitalized at $1,000,000, in shares of the par value of $100 each. Ten or twelve years ago there was considerable activity in the district, and the Provincial Government built a wagon road seven miles long, which passes our property and extends on to the Bonanza and Cascade mines. Both those properties at one time shipped considerable ore, and I have reason to believe that a Philadelphia operator will shortly arrive in Rossland to get them in shape for a resumption of production."

GENERAL MINING NEWS.

NOVA SCOTIA.

North Sydney, July 20.—A fatal accident occurred at Sydney Mines at 1.30 this morning, the victim being John McIntyre, a resident of the Cranberry district. McIntyre was lying across the track at a point known as the hollow, when the two o'clock workingman's train bound to No. 1 Colliery passed over him, severing his legs just above the ankles. He lived only twenty minutes after the accident. The train was drawn by engine No. 11, in charge of Daniel Nicholson and John W. Young, and was making the run at barely an average speed.

Another accident attended with fatal results occurred at Reserve last evening which caused the death of Joseph Hennessy. The deceased had been working on a level and had a leg badly crushed by a heavy stone falling on it, which rendered amputation necessary. The shock of amputation proved too much for the young man, and he succumbed. The deceased was 28 years old.

The latest reports from Port Hood mine, which was flooded recently, indicate that the mine may yet be saved.

A well known mining man who returned from there yesterday, spoke interestingly of the situation. Panic is on, and the people are leaving the town as fast as they can get away. The merchants are left in a bad predicament, not only on their future business but on their accounts, as the miners are leaving the town.

The traveller referred to spoke of being in one man's store who had been starting an addition to his place when the disaster occurred, and of seeing the tears roll down his cheeks as he tried to tell how his plans had been shattered.

There seems to be still some reason to hope that the mines can be saved. The water flows in at the rate of 35,000 gallons a minute, but there are at Inverness two pumps which are each capable of taking out that much water in the same time. They were sent down to Inverness last year by the Government and were used there.

Halifax.—The Board of Examiners of Mine Managers, Underground Managers, and Overmen has completed the examining of the papers of the candidates for such positions in the coal mines of Cape Breton, Inverness, Pictou, and Cumberland. The number to take the examinations this year was the largest yet, and out of the 126 men to take the examinations, 71 were successful in passing. The large number to take the examinations is due to the interest that the men take in their work, and to the mining schools throughout the Province is due the credit for the large percentage of successful candidates.

Those who were successful in the examinations were as follows:

Cumberland County—For Underground Managers — James Fairlay, Moses Jones; For Overman — Jos. H. Smith, Edward Bradley.

Inverness County — For Manager — D. A. McCuish; For Overman — Mark Davidson.

Pictou County — For Manager — Robert Henderson, James Brown, E. E. O'Reilley, M. E. Copeley, Dan. Gillis, Henry Henderson, John H. McNeil, James F. McDonald; For Underground Manager — Phillip Kennedy, George W. Burnley, Jos. Chisholm, James A. Clarke; For Overman — Jno. H. McDonald.

Cape Breton County — For Manager — F. B. Ferguson, Thomas Merritt, D. H. McLean, James Connors, Alex. McDonald, Ed. Lockman, John Hunter, John A. McLellan, William R. Coll, Thomas M. Kavanagh, William T. Chew, F. R. Dunn, W. G. Ross, A. D. Matheson, P. E. Morrison, Angus McDonald.

For Underground Manager — Phillip Kelly, James Costello, John Bisson, John Young, John A. Ferguson, David Morrison, James W. Spencer, W. E. L. Hall, John D. McNeil, Michael J. McNeil, Edward Cameron, Alex. McKay, Rory V. McNeil, Scott M. Irvin, Alex. H. McVicar; For Overman — Fraser Hynes, John F. McKinnon, Thomas J. Casey, David A. Robertson, Edward Casey, Joseph Gillis, Richard Walsh, Fred Jardine, Joe D. McNeil, Evan Prothers, Robert E. Walton, George Morris, John T. Foster, William Slade, Allan McIsaac, Henry Testall, Malcolm M. McNeil, Duncan H. McLeod, Pat J. Lynch, Con. Ahern, Walter Donovan.

The Board of Examiners consists of Isaac Greenwell, Sydney, Chairman; John Higson, Stellarton, Vice-Chairman; R. D. Anderson, Halifax, Secretary; John Gray, Inverness; Henry McCarthur, Minudie, Cumberland Co.; Thos. Hale, Westville; A. B. McGillivary, Glace Bay.

Halifax, July 12.—Bonds of the North Atlantic Collieries Company, with a face value of $110,000, were sold here this morning at auction to T. F. Tobin, barrister, for $29,200, or one-quarter of their par value. The bonds were offered for sale on account of the recent failure of the company to pay interest on them.

ONTARIO.

Ottawa, July 13.—The report of the majority of the Board of Conciliation and Investigation which ineffectually endeavoured to settle the differences between the miners and operators of British Columbia and Alberta mines has been given out by the Minister of Labour. The board consisted of Rev. C. W. Gordon, D.D., Winnipeg, chairman; Mr. Colin MacLeod, of MacLeod, Alberta, representing the companies, and Mr. A. J. Carter, of Fernie, B.C., named by the employees. The mines affected are located in Eastern British Columbia and Southern Alberta, the number of men affected being about 6,000.

The board intimates that much of the trouble would have en avoided if tyrannical pit bosses, on the one hand, and ddlesome secretaries of some of the local unions on the ner, were dismissed. There is said to be a lack of sincerity the part of both employers and unions in dealing with the estion of "open shop," and the recognition of the union. e board found an abnormally low scale for day wages, and normally high scales for the more difficult and dangerous ployment known as "pillar" work, the discrepancy ranging 74 and $8.88 for an average daily wage on the same mine. another mine, where the average net daily earnings of con-ct men for the year are $6, individual earnings vary from to even $20 a day. The board found that out of 18 com-anies concerned, only four have paid any dividends, and these y intermittently, while in the past two years two-thirds of mines have been operated at a loss. The board recommends t the rate for "pillar" cost be reduced, and the lower rate wages increased, according to a schedule submitted. This hedule would increase the total day wages by about $280,000, l reduce the "pillar" scale by about $46,000, leaving a net rease in companies' pay rolls of $234,000 a year.

The schedule of wages recommended by the board is:

1) That the day wage scale be increased as follows: 10 per t. advance up to $3 a day; 8 per cent. advance for $3 to 50; 5 per cent. advance over $3.50.

2) Differential of 5 cents to 7 cents per ton in all pillars sently without a differential, the application to be by mu-l consent.

3) Adjustment of the contract rate at the Lille mine so as make the rate proportionate to the size of the seam.

4) An advance of 3 per cent. on contract rates at Leth-dge.

5) All other contract rates to remain unchanged.

After referring to the neglect of sanitation and of pre-tions against disease and overcrowding, the report says: he board cannot but express its profound regret that no-ere could it discern indications of a sincere and earnest empt on the part either of a company or of a local union to mote the social, moral, and intellectual well-being of the rkers in the mines. Earnest and intelligent co-operation here uld surely be productive of the best results."

ttawa, July 24.—In consequence of communications re-ved by the Minister of Labour from Hon. C. N. Mitchell, ting Premier of Alberta, and Hon. Mr. Calder, ing Premier of Saskatchewan, representing the probable ve effects upon their Provinces of a shortage of coal should dispute in the western mines be prolonged, the Government is considering the duties on all coal imported into the west-e Provinces, pending the resumption of work in the mines.

oronto, July 13. — The much-discussed flotation of the th-Armstrong properties in Porcupine is now in process of ng underwritten, and will be placed on the market in the rse of a fortnight under the name of the Plenarium Gold nes, Limited.

he company is capitalized at $2,500,000, of which $500,000 l be held as treasury stock. The shares, which will have a value of $5 each, probably will be listed at $2.50.

he directors of the new mine include: Mr. R. B. Watson, the Nipissing and La Rose; Mr. W. S. Edwards, Mr. David ken, and Mr. E. P. Earl.

ALBERTA.

MacLeod, July 24.—Delegates to settle the coal strike, ch has utterly destroyed business over a large area for six ths, are in MacLeod to-day. Both sides to the dispute are present and the Presidents of the Boards of Trade of British Columbia and Alberta represent the people. The fuel situation could not be much worse on the prairies, where there is no wood to burn. President Barclay, Vice-President Pollock Secretary Moffat and other delegates are attending the meeting. All the delegates are anxious to see a settlement. The Crow's Nest towns are suffering from lack of business and the closing down of the enormous payroll has completely demoralized business. The prairie towns fear the prospects of a coal shortage.

BRITISH COLUMBIA.

Nelson, July 20.—The stamp mill at the Marvel mine, on Siwash Creek, in the Steamboat region, is doing excellent work. Dr. A. W. Mosely, of Vancouver, who is heavily interested in this property, recently visited the mine and mill and reports that the gold-saving apparatus recently added to the mill is working successfully and since the first of the month a saving of 80 per cent. of the gold values has been made.

Six stamps are in operation, working 18 hours per day, treating 24 tons of ore. Everything goes through the mill, the ore being obtained from the surface of the lead in a series of open cuts extending from wall to wall, a distance across the lead of 14 feet. The total product assays about $7 per ton. A Pelton wheel is used for the water power which runs the mill.

Vancouver, July 13.—Capitalized at $10,000,000, the British Columbia Steel Corporation, Limited, has announced that immediately at Port Mann construction will be undertaken of the first unit of the great steel plant, it is the ambition of the concern to build and operate. Plans have been decided upon for unit No. 1, which will cost $700,000.

A. P. Gillies, the moving spirit of the Corporation, has announced from Toronto, where the head offices are situated, that directors who have been chosen include the following local men: R. P. McLennan, president of the Bank of Vancouver; Robert Kelly, Clarence Marpole, Douglas Dominic Burns, John Stewart, of Foley, Welch & Stewart, and F. J. McDougall, barrister.

Material for use at the new plant has been thoroughly prospected and mined ready for use in the furnaces. The Canadian Northern has agreed to purchase from the new concern from 80,000 to 100,000 tons of rails for their system.

Vancouver. — Granby Consolidated has made payment of $250,000 on the bond for the purchase of an 80 per cent. interest in the Hidden Creek group of copper-gold mines on Goose Bay, Observatory Inlet, Portland Canal.

Development work, including diamond drilling has been in progress since the Granby was given a bond over a year ago. The property is now on a shipping basis, equipped with a compressor plant, ore bunkers and wharves and has several rich ore veins, but may be designated as a low grade proposition with enormous tonnage possibilities, one of the outcrops being over 40 feet wide.

The Hidden Creek group was purchased less than four years ago by J. T. Hillis, of Vancouver, from a syndicate, residents of Port Simpson, the price being $50,000. Two years ago Hillis, after doing certain development work, sold out in turn for $135,000 cash to M. K. Rodgers, of Seattle, and Tom Hodgins, of Butte. It is understood the Granby Company will ship Hidden Creek ore to the Ladysmith smelter until it erects its own reduction works at Goose Bay.

COMPANY NOTES

LA ROSE CASH.

La Rose, on July 1st, showed cash in bank and ore in transit and smelters $1,184,242, with ore sacked at mine ready for shipment at $162,311.

MOND NICKEL.

The report of the Mond Nickel Company, Limited, to 30th April last, to be submitted to the meeting on the 6th proximo, shows a balance to credit of profit and loss of £161,544. The directors propose to pay a dividend on the ordinary capital at the rate of 16¼ per cent. per annum (less income tax), and dividend on the deferred capital (less income tax) to the extent of £26,131, transferring to reserve £25,000 and to reserve suspense account £10,000, leaving to be carried forward £,139. In order to meet the increased demand, the directors decided to erect new and enlarged smelting works at Conis, near Romford Junction, Ontario, Canada, where an excel site of 3,700 acres of freehold land has been acquired for purpose. Further capital will be required for the comple of these works and for other purposes, and the directors pose to make an issue of debenture stock, of which a prospe will shortly be issued.

NIPISSING FINANCES.

Nipissing Mines' statement as of July 1 shows: Cash bank, $803,205; ore in transit and at smelters, $364,118; sacked at mine ready for shipment, $251,957.

STATISTICS AND RETURNS

COBALT ORE SHIPMENTS.

Following are the shipments from the Cobalt camp for the week ending July 14, and those from Jan 1, 1911, to date:

	July 14. Ore in lbs.	Since Jan. 1. Ore in lbs.
Badger	.....	55,200
Bailey	.....	40,000
Barber	.....	6,000
Beaver	66,000	845,208
Buffalo	50,324	1,456,184
Chambers-Ferland	.....	703,000
City of Cobalt	.....	557,980
Cobalt Lake	53,930	2,447,736
Cobalt Townsite	97,300	578,000
Colonial	.....	88,000
Coniagas	.....	2,171,734
Crown Reserve	133,419	1,408,839
Hargraves	.....	161,100
Hudson Bay	62,830	648,790
Kerr Lake	.....	1,382,090
King Edward	.....	40,000
La Rose	147,051	3,301,924
McKinley-Dar.-Sav.	128,129	3,291,734
Nipissing	61,600	3,580,328
O'Brien	64,118	737,158
O'Brien, M. J.	47,000	47,000
Peterson Lake (Little Nip)	.....	58,430
Provincial	.....	40,510
Right of Way	66,047	708,995
Silver Cliff	.....	106,680
Standard	.....	102,813
Temiskaming	85,900	946,752
Thethewey	.....	672,380
Wettlaufer	.....	117,232

The shipments for the week were 1,063,648 pounds, or 531 tons.

The shipments from Jan. 1 to July 14 were 26,542,151 pou or 13,271 tons.

COBALT ORE SHIPMENTS.

Following are the shipments from the Cobalt camp for he week ending July 21, and those from Jan. 1, 1911, to date:

	July 14. Ore in lbs.	Since Jar Ore in ll
Badger	.....	55,200
Bailey	.....	40,000
Barber	.....	6,000
Beaver	.....	845,208
Buffalo	58,300	1,514,484
Chambers-Ferland	64,000	767,000
City of Cobalt	.....	557,980
Cobalt Lake	.....	2,447,736
Cobalt Townsite	.....	578,000
Colonial	.....	88,000

TORONTO MARKETS.

July 25.—(Quotations from Canada Metal Co., Toronto.)

Spelter, 5.85 cents per pound.

Lead, 3.75 cents per pound.

Antimony, 8 to 9 cents per pound.

Tin, 45 cents per pound.

Copper, casting, 12.85 cents per pound.

Electrolytic, 12¾ cents per pound.

Ingot brass, 8 to 12 cents per pound.

GENERAL MARKETS.

Coal, anthracite, $5.50 to $6.75.

Coal, bituminous, $3.50 to $4.50 for 1¼-inch lump.

July 21.—Connellsville Coke (f.o.b. ovens):

Furnace Coke, prompt, $1.40 to $1.45 per ton.

Foundry Coke, prompt, $1.90 to $2. per ton.

July 21. Tin, Straits, 42.20 cents.

Copper, Prime Lake, 12.78 cents.

Electrolytic copper, 12.62½ cents.

Copper wire, 13.75 cents.

Lead, 4.57½ cents.

Spelter, 5.77½ cents.

Sheet zinc (f.o.b. smelter), 7.50 cents.

Antimony, Cookson's, 8.50 cents.

Aluminium, 19.75 to 20.25 cents.

Nickel, 40.00 to 45.00 cents.
Platinum, ordinary, $42.50 per ounce.
Platinum, hard, $44.50 per ounce.
Bismuth, $1.80 to $2.00 per lb.
Quicksilver, $5.00 per 75-lb. flask.

Silver Prices.

Nissen Stamp Mill

The Nissen Stamp Mill

STAMP. The Nissen Stamp drops with great crushing effect upon a feed comparatively free of the fines caused by preceding impacts. This causes an actual splash which radiates from the centre of the die carrying the pulp to a circular screen, every aperture in which presents a full opening for the pulp which has already reached size to pass through. As the stamp ascends preparatory for the succeeding blow, a partial vacuum is formed under stamp shoe, which greatly assists the rapid return of the oversize to the die. The condition, the circular form of mortar, and the ascending stamp; lead to a suction effect which hastens the return of oversize to the die, a feature distinctive to the Nissen Stamp. Thus, a greater number of effective drops per minute is possible, resulting in greater capacity.

FEEDER. Each Nissen Stamp is provided with a tappet driven, automatic ore feeder of the Challenge type. This feeder is easily adjusted for different rates of feed, and is very sensitive in responding to the action of the stamp.

MORTAR. The Nissen Mortar is circular in plan and made to accommodate but one stamp, thus confining the crushing zone to a field of activity which forbids pulp coming to rest or becoming sluggish in that circulatory movement essential to efficiency.

Boston Consolidated type "B" Nissen Mortar.

The screen of the Nissen Mortar is circular and extends more than half way around the mortar, forming an area of discharge for one Nissen Stamp equal to about two-thirds that employed for five stamps of the old type.

whether you mill, smelt or ship your ores you must have assays and analyses of unquestionable accuracy reported to you in the shortest possible time. Our equipment is especially designed to meet these requirements.

WE also test ores in a practical way to determine just what metallurgical process is best adapted to it to secure the highest commercial results. Write us for prices for your particular problem.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show indications of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

DEPARTMENT OF MINES. GEOLOGICAL SURVEY.

PUBLICATIONS

The Geological Survey has published maps and reports dealing with a large part of Canada, with many local areas and special subjects.

A catalogue of publications will be sent free to any applicant. A single copy of a map or report that is specially desired will be sent to a Canadian applicant free of cost and to others at a nominal price. The applicant should state definitely the precise area concerning which information is desired, and it is often of assistance in filling an order for a map or report if he states the use for which it is required.

Most of the older reports are out of print, but they may usually be found in public libraries, libraries of the Canadian Mining Institute, etc.

REPORTS RECENTLY ISSUED:

CANADA

1085. Descriptive Sketch of the Geology and Economic Minerals of Canada. Accompanied by a geological and mineral map of Canada, by G. A. Young and R. W. Brock.
1170. Summary Report of the Geological Survey for 1910.

NEW BRUNSWICK and NOVA SCOTIA

1107. Joint Report on the Bituminous or Oil Shales of New Brunswick and Nova Scotia. Also on the Oil Shale Industry of Scotland. Part I, Economics, Part II, Geology by R. W. Ells.

QUEBEC

1110. Memoir No. 4. Geological reconnaissance along the line of the National Transcontinental Railway in Western Quebec, by W. J. Wilson, accompanied by a map.
1064. Geology of an area adjoining the east side of Lake Timiskaming, by Morley E. Wilson.

ONTARIO

1091. Memoir No. 1, Geology of the Nipigon Basin, Ontario, by A. W. G. Wilson.
1137. Memoir No. 10 An instrumental survey of the shore-lines of the extinct lakes Algonquin and Nipissing in South-western Ontario, by J. W. Goldthwaite.

NORTH WEST PROVINCES

1035. Coal Fields of Manitoba, Saskatchewan, Alberta and Eastern British Columbia accompanied by a map, by D. B. Dowling.
1115. Memoir No. 8. The Edmonton Coal Field, Alberta, with maps, by D. B. Dowling.

BRITISH COLUMBIA

1139. Memoir 11-T Triangulation and Spirit Levelling of Vancouver Island, 1909, by R. H. Chapman.

YUKON and NORTH WEST TERRITORIES

1101. Memoir No. 5, Lewes and Nordenskiold Rivers Coal District, Yukon Territory, by D. D. Cairnes.
1080. Report on a part of the North West Territories drained by the Winisk and Attawapiskat Rivers, by Wm. McInnes.
1006. Report on a traverse through the southern part of the North West Territories from Lac Seul to Cat Lake in 1907, by A. W. G. Wilson.
1130. Memoir No. 9. Bighorn Coal Basin, Alberta, by G. S. Malloch, accompanied by a map.

MAPS RECENTLY ISSUED:

CANADA

1042. Mineral Map of Canada. Scale 100 miles to 1 inch.
1084. Geological Map of Canada. Scale 100 miles to 1 inch.

NOVA SCOTIA

1133. Map 13 A. Kingsport sheet, Nova Scotia, No. 84. Scale 1 mile to 1 inch.
1134. Map 14 A. Hall Harbour Sheet. Scale 1 mile to 1 inch.

NEW BRUNSWICK

1156. Map 25 A. Nipissiguit Iron Deposit, Gloucester County, N. B. Geology and topography, scale 400 feet to 1 inch.

QUEBEC

1066. Map 18 A, Lake Timiskaming Mining Region. Scale 1 mile to 1 inch.
1112. Map 12 A. Vicinity of the Transcontinental Railway, Abitibi District, Quebec. Scale 4 miles to 1 inch.
1154. Map 23 A. Thetford-Black Lake Mining District. Scale 1 mile to 1 inch.

ONTARIO

1091. Map 8 A, Lake Nipigon, Thunder Bay District, Ontario. Scale 4 miles to 1 inch.

ALBERTA

1132. Map No. 7A. Bighorn Coal Area, Alberta, by G. Malloch. Scale 2 miles to 1 in.

BRITISH COLUMBIA

1068. Geological Map (sketch) of the Sheep Creek Mining Camp, West Kootenay, B.C. Scale 1 mile to 1 inch.
1164. Map 28 A, Sketch map of Portland Canal Mining District.

YUKON and NORTH WEST TERRITORIES

1089. Map 9A. Explored Routes on Parts of the Albany, Severn and Winisk Rivers. Scale 8 miles to 1 inch.

NOTE.—Maps published within the last two years may be had, printed on linen for field use. A charge of 10 cents is made for maps on linen.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon. Letters and samples that are of a Departmental nature, addressed to the Director may be mailed O.H.M.S. free of postage.

Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.

The Mineral Province of Canada

produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; $,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has n even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the minion, or than any Colony of the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by own Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

A MESSAGE

TO

MINE SUPERINTENDENTS

WHO HAVE

IDEAS OF THEIR OWN

We will build your Skips, Ore-cars, Sinking Buckets, etc., to your own drawings, and exactly as you want them, or we will submit drawings for your approval.

DON'T let anybody force **CHEAP STOCK CARS** on you, when you can get them built as you know they ought to be.

You will find our cars in every Mining Camp in the North.

We are also prepared to furnish Tube Mill Liners. Chilled Wheels and Castings of all descriptions.

THE
SUDBURY CONSTRUCTION & MACHINERY CO.
LIMITED
SUDBURY :: ONTARIO

Province of Quebec

Department of Colonization, Mines, and Fisheries.

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, Etc.

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

MINERS' CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10.00 and it is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $10 an acre for SUPERIOR METALS when more than 20 miles distant from a railway and $20 an acre when less than 20 miles.

For INFERIOR METALS the prices are $2.00 and $4.00 an acre respectively.

The attention of prospectors is specially called to the territory in the North-Western part of the province of Quebec, north of the height of land, where important mineralized belts are known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY 228 ST. DENIS STREET, MONTREAL, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The Bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

THE HONORABLE THE MINISTER OF COLONIZATION, MINES, AND FISHERIES, QUEBEC.

Province of Nova Scotia

Leases for Mines of Gold, Silver Coal, Iron, Copper, Lead, Tin

AND

PRECIOUS STONES

Titles given Direct from the Crown, Royalties, and Rentals Moderate

Copies of the Mining Law and any information can be had on application to

The Hon. Christopher Chisholm

Commissioner Public Works and Mines, - - HALIFAX, NOVA SCOTIA

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

WANTED

AGENCY FOR ORES AND MINERALS.

An Ore Merchant who has connections with all the blast-furnaces and electro-metallurgical firms of France desires to communicate directly with firms who produce or sell:—

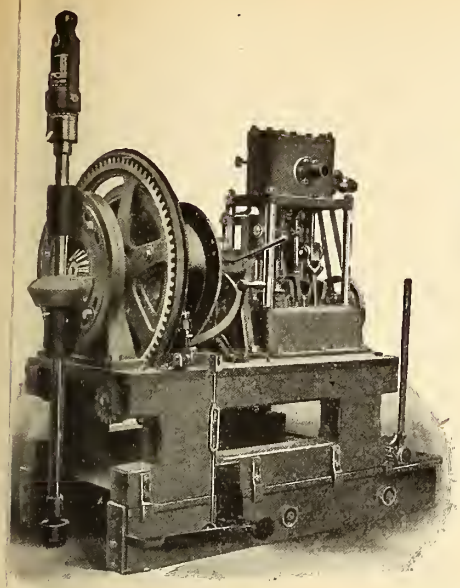
Chrome Ore; India, Brazil, or Caucasus Manganese Ores; Graphite; Tungsten Ores; Molybdenite Antimony Ores; Iron Ores; and Asbestos.

It is desired to purchase Ores outright, or to take over Sales.

AGENCY FOR FRANCE:—

Address—Mr. Ch. CHAUTEN,
123 Rue Lamark, PARIS.

CORE DRILLS



CLASS C.

We manufacture Machines for boring any size hole to any depth. They will do your work cheaper and quicker and give you more core per foot drilled than any other core drill made.

Our machines will bore at any angle up to 45°.

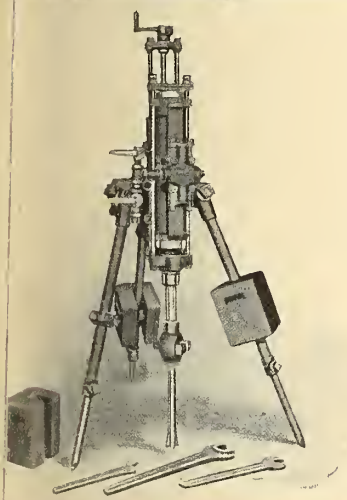
Can be operated by steam, gasolene, electricity or air.

For full information write to

McKIERNAN-TERRY DRILL CO.,

PHIL. H. MOORE, CANADIAN REPRESENTATIVE

KING EDWARD HOTEL, TORONTO.



The "Wizard" Rock Drill will drill a greater number of feet per day, per month or per year, with less power consumed per foot drilled, than any other piston rock drill of like size now manufactured.

ANNOUNCEMENT

THE CANADIAN MINING JOURNAL'S

PORCUPINE SERIES

VOLUME I.

A SERIES OF UNIQUE ILLUSTRATED ARTICLES.

Accompanied by a Complete Geological Map and Claim Maps of the Various Townships

The Publishers of *The Canadian Mining Journal*, in view of the fact that the demand for back numbers containing articles on Porcupine cannot be met, are bringing out a book embodying descriptive, geological, and general data relating to Porcupine. The latest available township maps and a large Geological Map will be included. The object of the publishers is to present in compact form a book that will guide the investor, the engineer, and the general reader.

The book will be on sale within a few days.

The price is $2.00 per volume. For orders of more than ten volumes a reduction of ten per cent will be made. The edition is limited.

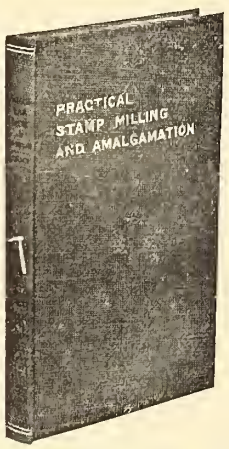
FOR THE MILLMAN

Practical Stamp Milling and Amalgamation

By H. W. MacFARREN

166 PAGES INDEXED

$2 POSTPAID



Written primarily for the millman himself, this book will prove of value to all those having to do with the milling of gold ores. Gives details needed in everyday work. The stamp mill, its location, and design; the mortar, die, shoes, tappet, and cam; adjustment of height, order of drop, feeder, and screens; water supply and power; principles of amalgamation and treatment of plates; retorting; loss of gold, mill tests, and mill management; all these are treated in an illuminating manner by one who has himself solved the problems.

Book Department

KINGSTON, ONT.

MINING AND SCIENTIFIC PRESS

Controlled by T. A. Rickard — Established 1860 — H. Foster Bain, Editor — Published weekly — Thomas T. Read, Associate Editor

In every issue valuable articles are published on mining, metallurgy, and geology, the latest news from special correspondents at the principal mining centers, letters giving the ideas and experience of successful men, and other items of useful knowledge.

THE MINING MAGAZINE

Established September, 1909

T. A. RICKARD, Editor — Published monthly at London, England

A monthly magazine is the natural corollary of a technical weekly. It permits of more deliberate and more extended notice of matters concerning which the news element is less important.

The Mining Magazine includes a review of the world's progress in mining, metallurgy, and economic geology, written by men who have personal knowledge of the regions and conditions discussed.

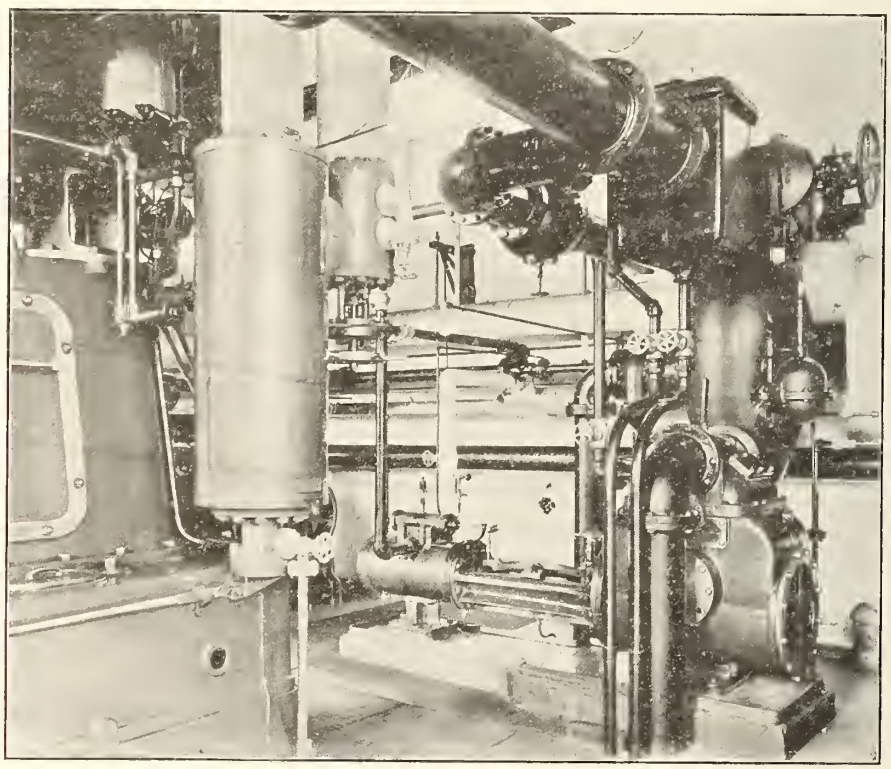
ECONOMY OF STEAM
IN
THE POWER HOUSE

The Condenser is as old as the steam engine itself, but has until very recently received far less consideration and has been treated as an auxiliary, the reliable working and efficiency of which had but little bearing upon the economy of the plant as a whole.

With the advent of the steam turbine and the demand for higher economies, the importance of the condensing apparatus has become more clearly apparent, and it now holds its rightful place as one of the principal parts of a steam plant.

Our independent air pump and jet cone condensing apparatus will save from 20 to 30 per cent. in steam when applied to non-condensing steam engines, or will give an increase of power of corresponding amount. It can be attached readily and placed in the most convenient place.

We get the best results by designing and building condensing apparatus specially to suit the conditions of operation.



Condensing Apparatus, Power House, City of Westmount.

THE CORE TELLS

The accompanying photograph shows four sections of a diamond drill core secured recently in drilling for limestone near Auburn, California, by the Mountain Quarries Co. The average length of the cores is nine feet four inches, and their diameter, $\frac{15}{16}$ of an inch. They were removed with a Sullivan "Class H" Diamond Drill, using a ten foot core barrel. The cores, it will be noted, form a perfect record of the rock formation from which they were cut.—"MINE & QUARRY,"

THE Core tells where your ore or coal is, what it is worth, and how best to reach it. It tells these things with an accuracy that cannot be doubted, and more quickly and cheaply than you can obtain this knowledge in any other way.

Amatite ROOFING

For Mine Buildings

AMATITE is exactly suited to mining buildings because:

1—It can be laid by unskilled labor.

2—It has a real mineral surface *which requires no painting.*

3—Its cost is lower than that of other ready roofings of less weight.

4—It comes in rolls ready to be unrolled on the roof and nailed down.

5—The necessary nails and cement are supplied free, packed handily in the center of each roll.

The mineral surface of Amatite is somewhat of a novelty; and the fact that it obviates the old painting nuisance, is giving to this roofing the leadership of the ready roofing industry.

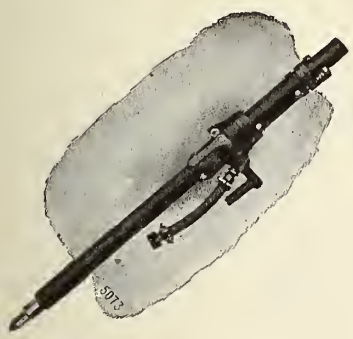
The surface consists of mineral particles embedded under great pressure into a tough plastic matrix of pitch.

A sample of Amatite will be sent free on request.

The PATERSON MFG. Co., Limited
Montreal, Toronto, Winnipeg, Vancouver, St. John, N.B. Halifax, N.S.

TELESCOPE FEED

HAMMER DRILLS



In the mind of the mine manager there can be no doubt of the superiority of the "BC--11" Telescope Feed Hammer Drill over the piston drill, for up holes. Its principle is right; the entire power consumption is concentrated upon operating the hammer.

No energy is consumed in the friction of reciprocating a long steel in a rough hole. The force of the blow is perfectly directed to the cutting point, and the maximum cutting rate is accomplished with the minimum of power.

The number of wearing parts is reduced to the limit of efficiency, and each part is made for endurance.

Rand designs are governed by years of successful rock drill experience, and embody the most advanced ideas in hammer drill construction.

PORCUPINE TO-DAY.

The astonishing recovery of Porcupine from the effects of the fire is stirring proof of the vigour and elasticity of our mining population. It is hard to conceive of any other class of people going so resolutely about the task of rehabilitation.

The public response to the request for assistance was prompt, and, in effect, adequate. There may have been incidental misunderstandings in the administration of relief, but there has certainly been no ground for grave criticism. The various committees gave their services voluntarily and without stint.

Particularly to be commended was the attitude of the Temiskaming and Northern Ontario Railway Commission. Disregarding everything but the relief of suffering and the immediate needs of the homeless, the commission worked valiantly. The value of its efforts may be best estimated when one attempts to picture what might have happened had there been no rail connection between Kelso and Porcupine Lake. It is not too much to say that the commission has brought credit to itself and to the nation. Whatever criticisms it may receive in the future, and no public corporation can hope to escape criticism, the historic incidents of the days that followed the fire will always stand out. Although much of the commission's property and supplies was destroyed, yet no thought was taken of this. The duty of the hour was faced.

As an example of what organization and well-applied wealth may do, we may cite the case of the Dome Mining Company, the chief loser in the disaster. Within an incredibly short time after the fire, a private car was hurried to the scene. Then, under the direction of Mr. Ambrose Monell, the whole situation was canvassed. After the first necessary steps towards ameliorating local hardships, the plan of campaign was outlined and actually begun. The decision was reached to erect a fire-proof group of buildings for residences, in a carefully chosen plot of ground. It was decided further to make all the plant buildings fire-proof throughout. Not a fortnight had elapsed when the company had 250 men again at work, with an ample commisariat organized. Feeding, sheltering, and directing this number of men is no mean accomplishment. The result, it is hoped, will be that a new mill will stand complete before winter has set in.

* * * * * * *

It were impossible to recite a tithe of the genuine acts of bravery that have been brought to our own notice. And it may be noted here that the real heroes are going quietly about their business, whilst several advertised individuals will scarcely receive a warm wel-

come in camp. Above all petty incidents, however, emerges the fact that the race has not degenerated. Men are still men.

* * * * * * *

Soon all physical traces of fire, save sundry square miles of scorched timber, will have been obliterated. Golden City, Pottsville, and South Porcupine will resume their normal aspects. Town lots are selling rapidly in the first and last named places, and the newly selected Timmins townsite is the scene of a real estate boom.

We believe that the new townsite will be laid out with due regard to sanitation. Unless, however, something is done very rapidly there will be a catastrophic outbreak of typhoid at Golden City and at South Porcupine. The state of affairs at the former settlement is exceedingly bad. There appears to be only indifference on the part of those officially responsible. Whereas the fire cost four-score lives, an epidemic of typhoid would take its toll of hundreds. Concerted effort on the part of the citizens themselves is now essential. With the aid of the Government, it is not too late to meet the situation. It will be shameful if the lesson learned in Cobalt be forgotten.

* * * * * * *

Rail connection has wrought vast change in Porcupine. Construction of plants is, of course, immeasurably facilitated. Living is made easier. The best of provender is obtainable. In fact, Porcupine is a full-bloom mining camp, with its hotels, restaurants, amusement halls, and most of the other perquisites that appertain to life under such conditions.

* * * * * * *

Not to be overlooked in any survey of Porcupine is the high standard of the men that are in charge of the mines. This is a direct inheritance from Cobalt. The "four-flusher," an unmitigated evil, became unpopular through Cobalt experience. He is not much in evidence in Porcupine. Cobalt has seen to that.

In the main, the sound engineers are successful in restraining their employers from early extravagance. It is gratifying to observe that the passion for mill-buildings and plant is being curbed. A wise balancing of mine and equipment will be thus attained.

* * * * * * *

Two favourite themes of discussion in Porcupine itself are the sins of the T. & N. O. Railway Commission and the vagaries of the Bewick-Moreing people.

As to the former, it is only necessary to state that the commission is fallible. It has, nevertheless, lived up to its promise. Its lines are fearfully and wonderfully congested with freight that cannot be handled by the consignees. Possibly 500 cars await unloading. We may add that but few strictures come from responsible sources. The incidental discomfort of sitting all night on a station platform is exasperating. But one can survive even that.

For the Bewick-Moreing concern we have little to say that is good. Their market manipulations have been cheap and undignified. Their mining methods and their mining men are of a high order of excellence. Why the firm cares to descend to the level of a broker's office is hard to understand. They have sown the wind; of a surety they will reap the whirlwind.

At least 150 people arrive in Golden City daily. The influx is growing larger. Difficulties are arising in accommodating the newcomers. With a settlement and mine population that may now amount to six or seven thousand, and that is growing every hour, the railway and the hotels are being taxed heavily. It is to be hoped that both will be able to cope with the situation.

* * * * * * *

Considerable attention is being diverted to the Swastika region. The traffic at that getting-off place is large. Yet there is no station building at Swastika. This omission, for which there is no valid excuse, must be remedied at once.

* * * * * * *

To refer to the mines themselves, there is no particularly noticeable change. Three spectacular surface discoveries have been made. Actual mining progress is slow, and will be slow, until such time as the principal plants have been rebuilt. Considered generally, the number of *bona fide* mines will probably be larger than was thought a year ago, although substantial production of gold has been deferred.

In forecasting the future of Porcupine it must not be forgotten that the district as a whole must write off a large debt of expenditure. The railway from Ke is a debit item, as are all outlays on prospecting, on fees, on roadbuilding, on mining, and on travelling expenses. If this chastening thought be kept in mind, it will temper the soulful enthusiasm of those who compare Porcupine with the Rand.

* * * * * * *

In a forthcoming special issue, to be published within a few weeks, the *Canadian Mining Journal* will report in detail the leading physical facts of the camp. The purpose of this editorial is entirely general.

GETTING DOWN TO CASES.

On another page will be found a letter from W. W. Cory, Deputy Minister of the Interior. In this letter reference is made to an editorial entitled "A Modern Instance," that appeared in our issue of June 15, 1911. Mr. Cory, we fear, has mistaken our point, and certainly has not attempted to meet our criticism.

To set forth the whole matter clearly, let us quote first from the editorial in question. Our own words were as follows:—

"Two men made application for a coal mining location in the west, covering 5,160 acres. All the requirements of the regulations were fulfilled as regards staking, making proper application, and making

e necessary deposits of $5 each. The stakers had en thirty days from the date of staking wherein to t in their application. After that application had en considered favourably by the Department at ttawa, *a process covering two months,* they were ven another thirty days in which to make payment the annual rental of $1 per acre, a total of $5,160."

o these remarks, Mr. Cory takes exception thus:—

enclose herewith for your information a copy of e Coal Mining Regulations, which have been in force nce the 25th day of May, 1910, from section 16, of hich you will see that payment of the rental must made to the Agent of Dominion Lands within thirty ys from the date of the receipt of his application the office of such agent."

ection 16 reads as follows:—

If the application is granted, the locator shall be otified in writing, and he shall be given a period thirty days from the date of the receipt of his pplication within which to pay to the Agent of ominion Lands the full amount of the rental for the rst year of the term of the lease, at the rate of one ollar ($1) per acre, and upon the receipt of such ntal the lease shall be issued and shall bear date om the day upon which the application was granted. the rental is not paid within the time specified, the pplication shall absolutely lapse, and the rights ap- lied for shall become available for other disposition."

he first clause of section 16 is the keynote of the ter. But before making further comment let us e the authentic history of the instance on which our ner editorial was based.

ear Brule Lake, in the vicinity of the Yellowhead s, two coal claims were staked last spring. The kers were Messrs. Scovil and Bartholomew. The ual rental for their leases was payable on May 3rd. yment was not made. Information to this effect ched the ears of an investor who was anxious to re the territory. The investor's representative ed upon the Dominion Land Agent at Edmonton, l from that official obtained confirmation of the fact t the rental had not been paid. He therefore hurried the ground, with the intention of staking. Arriving re on May 4 he found, in addition to the original stak- s, stakings dated in April in the name of a third per- , and more recent stakings dated May 4, one day after date on which payment of rentals was obligatory. e latter stakings were in the names of Messrs. Scovil l Bartholomew, and, of course, were valid, despite fact that they may have been made at any date be- e the old lease ran out.

We repeat, therefore, that this process of restaking ght easily go on indefinitely. According to the ulations the applicant is allowed 30 days in which to his application after staking. After the application iled, it is often a matter of months before the depart- nt decides to grant the lease. The applicant then s another 30 days in which to make payment of the rental of $1 per acre. If he is not able to pay, he can immediately restake.

We believe that this is a fair and full statement of the case. We shall leave it to our readers to judge how far Mr. Cory's strictures are justified.

THE UNDEVELOPED IRON RESOURCES OF CANADA.

Despite political vagaries, it may be believed that Canada's iron and steel industries have passed through the dangers and diseases of infancy. Amongst the world's producers of pig iron Canada ranks eighth, exceeding Sweden by a relatively large amount. Whilst, however, the production of pig iron is about 700,000 tons, it is not pleasant to note that the domestic output of iron ore hardly exceeds 250,000 tons, or roughly, about one-sixth of the quantity required to account for the pig iron produced. This measure of dependence upon foreign sources of supply is humiliating. Assuredly, we are lacking in enterprise or in acumen, or in both, when our attempts to exploit our mineral possibilities are so feeble.

As pointed out by Mr. A. B. Willmott, in a paper read before the Canadian Mining Institute, no official estimate of available iron ore in Canada has ever been made. No doubt the making of such an estimate would be extremely difficult. Yet it should be done without delay. One estimate, made by a member of the United States Conservation Commission, places the figure at less than fifty million tons. This is supposed to cover known ore. It can be but a small fraction of ore that can be almost as readily won. At best, it is the roughest kind of guess, and is significant only in so far as it shows the small amount of prospecting and development done.

What Sweden has accomplished, with opportunities not to be compared with Canada's, is alluded to in Mr. Willmott's paper. No country deserves more credit than Sweden for making bricks without straw. In face of most discouraging conditions, that small country has built up an industry that is almost as large, and, presumably, is much healthier than is the industry that we have artificially nourished.

HUNTING FOR MINES.

The much-quoted statement of Mr. S. J. Jennings, vice-president of the United States Smelting Company, to the effect that during the year 1910 that corporation rejected 514 mining properties, calls for comment. The additional facts that preliminary examination alone was made in 124 cases, that further work was done on 46, and that only two properties finally met the requirements of the company, require elucidation.

It can readily be understood that a corporation as large and powerful as is the United States Smelting Company knows definitely what it wants. Many limit-

ing conditions can be set and, as a matter of fact, are set, by such a purchaser. The possible scale on which any given mine, prospects are very rarely touched, is already developed, and the future promise that it holds, are deciding factors. Neither raw outcrops, nor small mines are wanted. The relation of the mine to transportation, to smelters, and to markets is also a vital consideration.

In short, companies like the United States Smelting Company are interested only in large mineral deposits that are developed sufficiently and are so circumstanced as to warrant investment.

Hence, it is beside the point to accept Vice-President Jennings' announcement as meaning anything more than that his company purchased only two mines in more than 500 mines and prospects. Of that large number, doubtless many are saleable. That they were not wanted by the company in question need not imply that they are worthless.

THE REPORT OF THE COMMISSION OF CONSERVATION.

A voluminous report has just been issued by the Canadian Commission of Conservation. The volume contains 519 pages. It is divided into three sections, the respective captions being "Lands," "Fisheries and Game," and "Minerals." In the last-mentioned section is presented a summary of Dominion and Provincial mining laws. This is followed by chapters on conservation and on mine accidents, and by statistical tables.

The diagrams and maps that illustrate the chapters on mining are excellent. Statistics are digested much more readily when graphically represented.

Much information is compressed into the pages dealing with conservation. Controversial points, we more or less regret to say, are avoided. The following quotations, referring to the Sudbury district, show the tone of the report:—

"It is not believed that the waste in mining is very "great."

"This loss of sulphur, copper, and nickel seems un- "avoidable at present."

This is certainly an improvement on the statements for which the commission was criticized.

The chapter upon mine accidents evidences careful preparation. It is informing and copious. We would suggest that it would have been well to include in the text a discussion of the methods of collecting statistics in various countries.

The report as a whole is most creditable.

THE FARMER FOLLOWS.

The solid basis upon which is builded the growth of Northern Ontario is well seen when the agricultural possibilities of the country are noted. Many thousands of acres have been cleared in the region that lies between Cobalt and Englehart. The quiet migration of farmers to this section has passed almost unnoticed in the large stream of mining population. But the farmer is there and is there to stay.

From our own observation, and from the reports of those more competent to judge in matters agricultural, it is certain that the soil is remarkably rich. With the question, the farmer of the north will wax fat and prosper. Doubtless he will have several large mining communities to supply with the necessaries of life. He must not fail, in the hour of his prosperity, to aeknowledge the debt he owes to his mining brother.

Nor is it inappropriate to remind the public and the powers that be of the fact that prospecting and mining open the way for the best and strongest settlement of the soil.

WOLFRAMITE IN NEW BRUNSWICK.

In the last number of Economic Geology there is a brief note by Dr. T. L. Walker, describing a recent discovery of wolframite in the centre of the province of New Brunswick.

For long it has been known that certain quartz veins near the confluence of the Miramichi River and Burnt Hill Brook contain molybdenite. Last year Dr. Walker examined the veins, and found that in almost every one wolframite occurs. More detailed examination has convinced Dr. Walker that these deposits may prove of commercial value.

CORRESPONDENCE

INVIDIOUS COMPARISONS.

Editor Canadian Mining Journal.

Sir,—The importance of the Porcupine district, like that of past gold discoveries in Ontario, is in danger of being too grossly exaggerated. While it has been stated by men who are qualified to judge that there are a number of properties in Porcupine likely to make producing mines, and while we know that several properties may already be called mines, yet it must not be overlooked that prospecting work in other sections of the field has failed to reveal discoveries of importance, and, consequently, interest in some cases has been transferred to other places.

One effect of over-advertising has been to alienate the English press. In addition to this, the market manipulations of the Bewick-Moreing people have done much harm. The 44,000 of the Hollinger shares that were acquired by the Northern Ontario Exploration Company, also 30,000 shares of the same concern that were held by a brokerage house in London, have been sold

w York and Toronto buyers. The fact that these s were not purchased by English investors is suf- t cause for alarm.

is true that the company made a profit of some- like $350,000 out of the Hollinger transaction. may be considered good business. But it is to be tted that the profits came out of the pockets of unfortunate stock gamblers, and not out of the Hollinger

is believed by many that at the present stage of opment the Hollinger mine does not warrant the paid for these shares, namely, $10 to $15. This out the opinions expressed by mining men dur- he Hollinger boom, to the effect that the shares ed a high point, not because the mine warranted it because of clever manipulation, supported by g organization.

Porcupine is to hold the interest of English and mental investors, there will have to be more sys- tic and vigorous development work, with less daily twaddle.

e attention attracted by Porcupine has certainly ded that roused by Cobalt, even in the latter's liest days. But it must be realized that gold has cination that no other mineral or metal possesses. st not be overlooked that Cobalt stands in a totally ent position than Porcupine. To be guilty of a guesses, I would say that there is to be written off st the future production of Poreupine $1,000,000 t in the construction of the railroad; $2,000,000 in ht and machinery; $50,000 in engineers' fees; 0,000 in the recording and performanee of two s' assessment work on claims staked in the Porcu- mining division; $175,000 in the incorporation of panies, etc.; roughly, about $5,000,000, not including sums of money spent in advertising the camp. le these guesses may be wide of the mark, the total obably less than the truth. It is scarcely reasonable pect that Porcupine will prove an exception to all r mining fields of the world. It is inevitable that ust go through the stage of paying for experience. ill have to pay heavily to work out the proper ods for its development, and for the treatment of res. Those who are acquainted with the history of of the important mines in America, Australia, and h Africa, can form some idea of the large amount oney lost through the adoption of wrong methods. must be expected in opening up any new mining . Not until a camp has gone through several stages evelopment can these mistakes be rectified.

ecently there have appeared in the daily papers ements to the effeet that Porcupine as a mining camp usurped the position held by Cobalt; also that it will e equal or even better than the Rand. Let us mine the matter. The position of Cobalt to-day is ue in mining experience. During the year 1910 it luced nearly 11 per cent. of the world's supply of r, valued at $15,375,000, and there is every indica- that during the present year the output will exceed by fully 20 per cent.

hen Porcupine is producing an annual yield of gold valent in value to the silver produced by Cobalt year, there will be some justice in the comparison.

or the benefit of the readers of this journal who are familiar with the Rand, I will attempt here briefly convey some idea of its vastness.

ohannesburg is situated 1,014 miles north of Cape n, and has an altitude of about 5,500 feet above the which assures a cool, pleasant, and healthy climate. Extensive artificial afforestation has made Johannesburg and its surroundings a place of beauty.

In July, 1886, a man named Struben first discovered gold in an outcropping of quartz, which is now known as the main reef leader. A quantity of the ore was sent to Kimberley to be assayed. When the results were known Kimberley mining men, such as Wernher, Beit & Co., Cecil Rhodes, and others, became interested. There was not the usual blare of trumpets. The daily papers did not display half-page advertisements telling the public of the richness of the field. It was done in that quiet manner characteristic of the true mining man.

The Rand series was found to consist chiefly of conglomerate shales and quartzites, resting on granite, and extending east and west. What may be described as one of the Rand's unique features is the fact that gold associated with pyrite is found in paying quantities in a series of conglomerate beds, extending over a great length and to an unknown depth. The trend of the producing zone on the Rand is almost due east and west, extending in a basin-like form for a distance of 62 miles. Over this distance the producing mines are spread. At a place called Klerksdorp, a little over 100 miles in an easterly direction from Johannesburg, the same deposit was found by boring. The deposit is carrying high values in gold, extending for 20 miles, and will be the means of creating another Johannesburg.

There are 72 producing mines on the Rand, with 9,836 stamps dropping, crushing on an average 2,000,000 tons of ore each month, producing nearly $13,000,000 worth of gold.

During the year 1910 the value of the gold output of the Witwatersrand amounted to $147,378,777.60.

One mine on the Witwatersrand has produced 4,801,075 tons of ore, which yielded $72,016,125, or an average of $15 to the ton, and has given its shareholders a handsome profit of about $33,000,000. A mine with a record behind it such as this is one of the glories of the mining industry. Fifteen mines on the Rand have individually contributed roughly $250,000,000 worth of gold to the world's supply.

Dividends declared for the half-year ending June 30, 1911, by companies operating on the Rand amounted to $20,424,085.

These figures are for the Witwatersrand only and do not include mines operating in outside districts in the Transvaal.

It is not my intention for a moment to belittle Porcupine. What I wish to show is that it is exceedingly foolish to institute comparisons between Porcupine and the Rand. Porcupine is more promising than any gold camp that Canada has ever developed. But I fail to see what earthly good can come of making insane comparisons where there is no room for comparison at all.

Temperate talk will do more for Porcupine than will all the shouting in the world.

Yours etc.,
GEORGE R. ROGERS.

Toronto, August 9, 1911.

A REMONSTRANCE.

Ottawa, 8th August, 1911.

Editor Canadian Mining Journal.

Sir,—My attention has been called to your editorial in the issue of "The Canadian Mining Journal" dated the 15th of June last, entitled "A Modern Instance," in which you point out that an applicant for a coal mining lease was given a period of three months from the date upon which his application was filed with-

in which to pay the rental for the first year; that being unable to raise the money he restaked the tract immediately after the expiry of the period given; and that he thus succeeded in postponing payment of the rental for another three months.

I enclose herewith for your information a copy of the Coal Mining Regulations, which have been in force since the 25th day of May, 1910, from section 16 of which you will see that payment of the rental must be made to the Agent of Dominion Lands within thirty days from the date of the receipt of his application in the office of such agent.

It seems manifestly unfair to criticize in so harsh a manner the regulations of this department without having some knowledge of their provisions.

Yours truly,

W. W. CORY,
Deputy Minister of the Interior.

Personal and General

Mr. W. K. McNeill, manager of the Canadian Laboratories, Ltd., has been placed in charge of the Ontario mineral exhibit at the Canadian National Exhibition. Mr. McNeill has just returned from Cobalt, Swastika, and Porcupine, in which places he made arrangements with the principal mines for suitable samples. The mineral exhibit promises this year to be much larger than ever. The directors of the Canadian National Exhibition recognize the importance of giving the mining industry the prominence that it deserves. Considerably larger space has, therefore, been assigned to the Bureau of Mines.

Dr. W. Harvey Weed is in Porcupine.

Mr. Dwight E. Woodbridge was in Toronto on August 5.

Mr. W. F. Ferrier, Lumsden Building, Toronto, has returned to town.

Mr. R. B. Lamb has been retained as consulting engineer for the Pearl Lake Gold Mines Company.

Dr. James M. Bell, M.A., Ph.D., Harvard (formerly on the staff of the Canadian Geological Survey, and lately director of the Geological Survey of New Zealand), and Mr. Colin Fraser, B.Sc. (lately mining geologist on the staff of the Geological Survey of New Zealand), have opened an office as mining geologists at 621 Salisbury House, London-wall, E.C.

Dr. Malcolm Maclaren is making a geological examination of properties on the Porcupine Goldfield, Ontario.

Dr. James Douglas and Messrs. W. R. Ingalls, J. Parke Channing, J. R. Finlay, and John Hays Hammond have been appointed consulting engineers in the United States Bureau of Mines, and will be constituted a committee within the bureau to continue the development of rules and regulations for the promotion of safety in metal mining, upon which they have been engaged heretofore as a committee appointed by the American Mining Congress.

Mr. G. G. S. Lindsey gave a luncheon on Saturday, August 5, at the National Club, Toronto, in honour of Mr. Hugh Marriott and Mr. Louis Reyersbach. Amongst those present were Dr. W. G. Miller, Mr. Dwight Woodbridge, Mr. A. B. Willmott, Mr. W. E. H. Carter, Mr. R. B. Lamb, Mr. W. Stanley Leckie, Mr. Eugene Coste, and Mr. J. C. Murray.

Mr. A. J. McNab, of Trail, B.C., superintendent of the smelting works of the Consolidated Mining and Smelting Company of Canada, Ltd., was in Nova at the end of July.

Mr. Andrew Laidlaw, of Spokane, Washington is largely interested in coal properties in Alberta British Columbia, recently went to Duluth, Minnesota, in connection with the prospective sale of valuable coal lands situated in the former province.

Mr. Thomas W. Lawson, of Boston, Mass., was a visitor to Portland, Seattle, Vancouver, and other fic coast cities. He returned east by the Canadian fic Railway, stopping en route at some of the favorite holiday resorts in the Rocky Mountains.

Mr. Donald G. Forbes, who some years ago was eral manager of several companies working mines the Lardeau district of British Columbia, recently turned to that province after an absence of about a in England. He purposes shortly proceeding to tralia.

Dr. Alfred W. G. Wilson, of the Mines Branch the Canadian Department of Mines, is in British Columbia obtaining information relative to the copper mining industry of that province, from which comes more two-thirds of the copper production of the Dominion.

Mr. D. C. Livingston, son of the late Mr. Cle Livingston (who organized, and until the time of death was general manager of, the Tyee Copper Ltd., operating mines and a copper smeltery in British Columbia), has been appointed associate professor the mining engineering department of the University of Idaho, Moscow, Idaho. Professor Livingston took his B.Sc. degree at McGill University in 1906, in which year he has been engaged in mining in Mexico latterly with the Moctezuma Copper Co.

Mr. Alexander Grant has voluntarily retired from the management of the Marble Bay gold-copper mine, Van Anda, Texada Island, B.C., after having been in charge there for between 11 and 12 years. During several recent months Mr. Grant had been under a surgeon's care, but, notwithstanding that he has been restored to good health, he has decided to relinquish the responsible duties inseparable from the active management of an operating mine. The Marble Bay mine was formerly owned by Mr. J. J. Palmer, of Toronto, is now the property of the Tacoma Steel Co., of Tacoma Puget Sound, Washington.

Circular from the U. S. Bureau of Mines

Compiled By John L. Cochrane.

Washington, D.C.—With the rapid development of mine rescue work in the United States in the last two years and the increasing use of the mine-breathing apparatus, there has come to the Federal Bureau of Mines a demand for information concerning the apparatus and how it should be properly used. In response the Bureau of Mines has issued Miners' Circular No. 4, on "The Use and Care of Mine-Rescue Breathing Apparatus," by James W. Paul, who has general charge of the rescue work. Mr. Paul makes the statement that the use of such apparatus for rescue work in mines is no longer an experiment, but has become an important factor in lessening loss of life and property from fires and explosions.

The circular describes the various types of apparatus used by the bureau and gives careful instructions for

are this apparatus should receive when not in Then the author passes upon the qualifications of e men at the mines. Mr. Paul says: "Mine men 45 years old, in good physical condition, who are erate in their habits and naturally calm and de- ate, are best suited for mine rescue work. Before n undergoes training in the use of breathing ap- us he should be examined by a physician to ascer- his physical condition, especially the action of his t and lungs, and any defects of the nose or t. Unless a man has a physician's certificate stat- hat his physical condition is good, he should not ermitted to take rescue training nor to attempt e work in a mine.

A rescue party should have not less than five, and r not less than six members. Only such persons ld be allowed to join the party as have already trained in the use of the apparatus and are pped with rescue apparatus in good order, and agreed to follow the directions of the leader, who have full charge. While working in unbreath- gases within a mine the men should keep close to another and not separate under any condition.

To be efficient and successful a party must take y precaution for its own safety. If one person in rty faints or receives an injury, he becomes a bur- instead of a help, for the entire party must at once luct him to the surface or to fresh air. One or stretchers should always be at hand.

A relief station or base of operations should be blished at the end of the good air and a relief with knapsacks should be stationed there ready ut on their apparatus and start at a moment's no- A patrol of all brattice and doors leading up to relief station should be maintained to protect the f crew from harm.

At each large mine there should be at least four vs, two outside and two inside crews, each of six , including a captain and a lieutenant, and these vs should have practice once a week.

While working in dense smoke the members of a y should hold a rope which leads to fresh air.

In case of total failure of an apparatus to supply thable air, the wearer of the apparatus can throw y all parts but the oxygen cylinder, and breathe n the cylinder through his mouth while endeavour- to reach fresh air with the rest of the crew.

Apparatus for giving oxygen to one who has been rcome with gases is an essential part of the equip- t of a rescue party.

A telephone helmet is a convenience for shaft k, and its presence lends much confidence to a res- party. Electric lamps, safety lamps, gas-analysis aratus, thermometers, a pocket compass, and a of the mine are necessary parts of the equipment.

At each training station a record should be kept wing the work done by the men and the difficulties ountered. A record of each apparatus should be t also. If an apparatus fails to give proper ser- it should be subjected to the regular tests unless e injury is seen by inspection.

he United States Bureau of Mines has established egular course of training in the use of mine-rescue athing apparatus. This training is designed to give ers or other persons connected with mining a know- ledge of breathing apparatus in general, and a confi- dent familiarity with those types of apparatus that are most apt to be used in this country.

"The purpose of the Bureau of Mines in establishing this system of training is to facilitate investigative work within mines in which disasters have occurred, and to make mine owners and miners acquainted with the value of breathing apparatus for rescue operations after mine disasters. It is hoped that, as a result of this work by the Federal Government in the near future, men familiar with such apparatus will be scattered throughout the coal-mining centres of the country, and be available on short notice to assist in rescue operations. After a disaster, valuable time is often lost in training men at the mine before rescue parties can be organized. Furthermore, a man can not work efficiently unless he has thorough confidence in the apparatus. To give a man this confidence, the course of training has been planned in such a way that he must do work in poisonous or unbreathable gases for periods of one and two hours at a time."

Porcupine Gold

Mr. Reginald E. Hore, in a paper published by the Canadian Mining Institute, discusses the modes of occurrence of gold in several of the Porcupine quartz bodies. In the Dome mine quartz, Mr. Hore found one grain of quartz, 0.5 by 0.8 mm. in section, completely enclosing three very small isolated grains of gold. One area of pyrite, 0.5 mm. by 1.0 mm., enclosed several irregular patches of gold, most of which were less than 0.1 mm. in diameter. Four of the gold grains were completely within the pyrite; but a much greater number were found to be partly enclosed by the pyrite and partly by quartz. Gold grains were found also in calcite, completely or partly enclosed; and in spaces between grains of coarsely and finely crystalline quartz.

In discussing the origin of these deposits, Mr. Hore favours the view that Porcupine ore bodies owe their origin to the same agencies that produced the gold-bearing quartz of California. Some gold, he believes, was deposited simultaneously with the original quartz of the veins. The pyrite, in part at least, appears to have been deposited from the same hot solution that carried the quartz and gold. Unlike the gold and quartz, the pyrite occurs scattered through the wall rocks. In fact, it is more abundant in the walls than in the veins. The relation of the carbonates to the quartz is not always clear. It is evident, Mr. Hore states, that the ferrodolomite of the wall rocks is older than the quartz.

Geologically, the Californian deposits referred to are the result of the intrusion of a quartz-mica-diorite into metamorphic slate. This metamorphic series consists of highly compressed and folded sediments. Among the igneous intrusives are augite-porphyrite, diabase, and serpentine.

The production of talc and soapstone in the United States reached 150,716 short tons in 1910. This is an increase of 16 per cent. in quantity. Of the eleven producing States, New York led, with 71,710 tons., 69 per cent. of the talc was ground, and 21 per cent. was made into slabs and manufactured. The New York product is nearly all ground.

List of Excursions of The International Geological Congress, to be held in Canada in the Summer of 1913

"A" Excursions.

A 1.—Excursion to Maritime Provinces.

At St. John and neighbourhood to visit Cambrian section, etc., one day and a half. Leaders, Drs. G. F. Matthews and W. Parks. Salisbury to Hillsboro and Hopewell, visiting Albert mines area, gypsum deposits, etc., one day. At Joggins section, examining cliff by walking and boats, one day. Passing the Bras d'Or Lakes, etc., by daylight. A day and a half at Sydney, visiting industrial plant, carboniferous section, etc. (A visit might be made to Louisburg by those desiring to do so.) Stop at Waverley gold mine; balance of day and next at Halifax. Leader, E. R. Faribault. By ferry to fish beds, etc., one day. By steamer to Perce and Grand Greve, etc., on Gaspe coast, visiting the very striking faulted sections of Silurian and Devonian exposed there, and return to Dalhousie, four days. Leader, Dr. Clarke. One day at Quebec seeing the city and the sections exposed in the neighbourhood.

Alternative Branch Excursion for Palaeontologists.

Omitting Sydney and Halifax; one extra day at Joggins section. To Antigonish by regular train and to Arisaig and return by carriage, giving two clear days at Arisaig, or on the return journey to Truro a day might be spent at the Riverdale locality. Leader, J. B. Tyrrell.

A 2.—Excursion to the Haliburton-Bancroft Area.

Leave Montreal. Leave Millbridge, drive to Ormsby Junction (or St. Ola.) This drive affords an excellent section across the Grenville series, one day. Leave Ormsby Junction (or St. Ola), arrive Bancroft. Go to camp at Bancroft and spend the remainder of the day in seeing the Crystalline Limestones, Nepheline-Syenites, Sodalite, and Fundamental Gneiss in this vicinity, one day. Leave Bancroft; drive to Mud Creek, about seven miles; take special train on Irondale, Bancroft & Ottawa Railway, stopping at a number of points of interest, and in the evening reach Gooderham. Camp at Gooderham, one day. At Gooderham visit Maxwell's Crossing and various other points, where the origin of the Amphibolites can be studied, and also visit the Nepheline-Syenite occurrences and the Gabbro, with its differentiation into Iron Ore, one day. Drive to Bancroft and then on to Bronson's Landing; the remainder of the day to be spent in further examination of the Geology in the vicinity of Bancroft, one day. Leave Bronson's Landing by canoe, paddling to Craigmont, making stops at two or three interesting points en route, at which occurrences of certain rare varieties of Nepheline-Syenite are to be seen, one day. At Craigmont study the Nepheline-Syenite and Corundum occurrenees, one day. Leave Craigmont, arrive Barry's Bay, stopping en route to visit some points of interest, one day.

A 3.—Sudbury-Cobalt-Porcupine Excursion.

The first two days at Sudbury will be spent in an examination of the mines and geology of the nickel-copper bearing area. The third day an excursion will be made from Sudbury to Moose Mountain, where the iron mine will be visited. The fourth day will be spent on the general geology of the pre-Cambrian; probably a visit will be made to the classic Huronian of Lake Huron. Leaders, T. L. Walker, Dr. Bar Dr. Coleman.

Three days will be devoted to the geology of Te gami, where good contacts of the Huronian and Keewatin are to be seen, and where there is a cha teristie outcrop of Keewatin jaspylite. At Cobalt, day will be spent in visiting the mines and charac istic outcrops of the pre-Cambrian series, which to be seen in striking exposures.

The members will leave Cobalt in the evening about a day will be spent in the Porcupine gold ca Those wishing to proceed to Montreal to take par short excursions will take the main line of the C adian Pacific Railway at North Bay. Leaders Temagami, Cobalt, and Porcupine, Messrs. Mi Knight, and Burrows.

A 4.—Niagara-Iroquois Beach Excursion.

One and a half days at Niagara Falls and Go Road. One day at Hamilton, Silurian on Moun and at quarries. Iroquois Beach, in city, and Burl ton Heights. Leaders, Messrs. Tyrrell, McNairn, nings, and Willmott.

A 5.—Asbestos Excursion.

Spend day at Thetford and take north bound tr arriving East Broughton. See East Broughton currences and mines, and Black Lake. Spend this on Asbestos and next day on Chrome. Leader, Denis.

A 6.—Morin Anorthosite Excursion.

Examine the Anorthosite in the vicinity of St. M guerite. Leave St. Marguerite, arrive St. Jerome. amine the Anorthosite occurrences at St. Jerome. Le St. Jerome, arrive New Glasgow, visit the occurre of Foliated Anorthosite as well as the Dark Gabl Crystalline Limestone, and the Anorthosite which cur in this locality.

A 7.—Excursion to the Monteregian Hills.

Visit Mount Royal, studying the Nepheline-Syen and Essexite Intrusions, as well as the Dykes and Contact Metamorphism of the Intruded Limesto Visit the Breccias at Outremont. Visit St. Hele Island, one day. Study of Mount Johnson. Arrive Gregoire, drive to Mount Johnson. Study there remarkably interesting Intrusive rock, showing varieties of Essexite passing over into Pulaskite, described by Dr. Adams, one day. Leader, Dr. Ada

A 8.—Apatite and Mica Region Around Ottawa.

Visit crystalline limestone and Potsdam escarpm at Lachute, one day. Visit Eozoon locality at Pa eauville. Visit Graphite deposits at Lake Donalds seven miles from Buckingham, and Apatite depo near Poupore, ten miles from Buckingham, one d Gatineau Valley trip. Visit Nellis mica mines, so of Cantley, and other points of interest in the vicin also Blaekburn mine, one day. Leader, Mr. LeRoy.

A 9.—Kingston Mineralogieal Exeursion.

Leave Kingston, visit Sydenham mica mine, Fr tenac lead mine, Apatite deposits, one day. Le Kingston, visit Verona, McDonald feldspar mine. G

wer iron mine. Richardson feldspar mine, one day. aders, Dr. Miller, Prof. Nicol.

A 10.—Excursion to the Drift Deposits of the District about Ottawa and Montreal (Including a Visit to Rigaud Mountain).

At various points in Montreal, study the terraces nich surround Mt. Royal. Visit the Mile End quarries and the brickyards at Maisonneuve. Here excellent sections may be seen of the Bounder Clay overlain the Leda Clay and the Saxicava Sand, the latter rmations holding an abundance of fossils, one day. rrive Ste. Anne de Bellevue. Visit the occurrences the vicinity, and arrive Rigaud Mt. Visit the Devil's arden and study the drift phenomenon in this vicuity, one day. Arrive Green's Creek, collect concreons in the clay. Drive to marine terraces and sands the Quebec side of Ottawa River.

A 11.—The Ordovician of the District about Ottawa and Montreal.

Visit morning at Cap St. Martin and Mile End, and fternoon at Grenville. Night at Hawkesbury, Chazy ossils, one day. Exposures of Chazy to the west. Drive to Caledonia Springs, one day. Ottawa, Queen's ark, Aylmer, Calciferous, Hull, Trenton, Rockcliffe, hazy, one day. Leaders, Messrs. Sowter, Billings nd Narroway.

A 12.—Palaeontological Excursion (Western Ontario.)

Brantford to fossil localities on the Onondaga and riskany, south of Waterford. Evening at Thedford, ne day. Fossils near Thedford and possibly Kettle oint. Evening to Guelph, one day. Fossils at Guelph, alt, Hespeler, etc., one day. Leader, Mr. Stauffer.

"B" Excursions.

B 1.—Niagara Falls. Dr. Coleman.

B 2.—Glacial and Interglacial, Don Valley, Glacial nd Interglacial, and Iroquois Beach, East Toronto nd Scarboro' Heights. Leaders, Dr. Coleman, Walker, and other local geologists.

B 3.—Hamilton excursion.

B 4.—Forks of Credit. Leader, Dr. Parks.

B 5.—Moraine north of Toronto. Leaders, Dr. Coleman, Taylor.

B 6.—Muskoka excursion.

B 7.—Oil Fields excursion. Leader, Dr. Parks.

B 8.—Palaeontological excursion to Streetsville. Leader, Dr. Parks

B 9.—Clay works around Toronto, Don, Milton, etc.

NOTE.—These excursions are left to the Local Committee to complete, they being empowered to arrange further excursions, to be reported to the Executive Committee.

"C" Excursions.

C 1.—C. P. R. Main Line to Vancouver.

Toronto to Sudbury. Nickel copper mines, geological excursion. Sudbury to Port Arthur. Stop en route at Loon Lake. Port Arthur to Kenora. (a) Lake of the Woods excursion. (b) Rainy Lake excursion. (c) Port Arthur excursion, No. 2. Port Arthur to Medicine Hat. Gas wells, coal mines 7 to 10 miles west of Medicine Hat, and Medicine Hat to Banff, coal mines, Bankhead, Anthracite, Canmore. Geological excursion. Banff to Laggan. Excursion to Lake Louise and Victoria Glacier. Laggan to Field. Yoho Valley and Mt. Stephen excursions. Field to Glacier excursions. Glacier to Siccamous, or Kamloops, or Nicola. Arrive Vancouver. Fifteen days.

C 2.—Toronto to Vancouver (via Crow's Nest).

Toronto to Medicine Hat. Visit gas wells, coal mines. Medicine Hat to Lethbridge. Coal mines, Geological excursion. Lethbridge to Coleman, coal mines. Geological excursion. Coleman to Fernie, coal mines. Fernie to Hosmer. Geological excursion. Fernie to Nelson, Moyie mines, geology. Trip on Kootenay Lake, Sheep Creek camp. Geological excursion (alternative with Rossland). Nelson to Rossland, mines, smelter. Geological excursion. Trail to Grand Forks, smelter. Geological excursion. Grand Forks to Eholt mines, at Phoenix and Deadwood. Geological excursion. Grand Forks to Hedley. Nickel Plate mine. Geological excursion. Hedley to Princeton and Tulameen, coal mine. Geological excursion. Diamond fields. Tulameen to Nicola, coal mines. Geological excursion. Nicola to Vancouver. Sixteen days. Leaders, Messrs. Brock, Camsell, Dowling, and LeRoy.

Alternative Route.

Tulameen to Keremeos. Keremeos to Penticton. Penticton to Okanagan Landing. Okanagan Landing to Vancouver; or Tulameen-Vancouver.

C 3.—Toronto to Vancouver, via C. P. R., C. N. R., G. T. R. and C. P. R.

Toronto to Edmonton. Excursions en route, Lake Agassiz, Lake Winnipegosis. Edmonton to Yellowhead Pass. Edmonton to Banff excursions. Banff to Glacier excursion. Glacier to Vancouver, fifteen days. Leaders, Messrs. McEvoy, Tyrrell, Dowling, and Coleman.

C 4.—Toronto to Edmonton (via Great Lakes.)

Stopping at fossil localities in Manitoba, Red Deer, Kicking Horse, with sub-excursions from Edmonton to Lake Athabasca.

C 5.—Excursion Lakes Erie and Huron.

It is proposed to conduct this excursion by means of a chartered steamer. Toronto to St. Catharines, to proceed to Port Colborne. Niagara Falls, one day. Morning at Falls, to Port Colborne, fossils near Port Colborne, or alternative, afternoon on glacial work, one day. Leave Port Colborne to make Pelee Island some time the next night. Physiographic features of Lake Erie shore during the day. Rondeau Park. Night on boat at Pelee Island, one day. Glacial striae and quarries, Pelee Island. Proceed to Amherstburg, quarries and Livingstone cut. Wampole Island, one day. Indians at Wampole Island. Sarnia. Port Frank light. Thedford, Hamilton fossils and Kettle Point, one day. Goderich, salt, one day. Manitowaning. Fossil Hill. Niagara and Clinton fossils, one day. Fossils near Manitowaning. Little Current. Trenton fossils and palaeozoic contacts, one day. Little Current to Parry Sound, via islands, one day. Parry Sound, Grenville, one day. Parry Sound to Collingwood, one day. Utica fossils at Collingwood, one day. Fourteen days.

C 6.—Cobalt-Sudbury Excursion as Before (to be repeated.)

C 7.—Alaska-Yukon Excursion.

This excursion would leave Vancouver after the three parties sent across the continent by different routes had all reached the coast.

The route would be from Vancouver to Skagway by steamer, Skagway to Whitehorse by rail, and Whitehorse to Dawson by river steamer. A short visit to the copper and iron deposits on Texada Island, and a trip up Portland Canal to Stewart. This canal or fiord cuts completely through the Coast Range and an opportunity would be afforded for studying the still unsettled question of fiord origin. The mineral de-

posits and glaciers of the Portland Canal District are also worth visiting.

From Skagway part of the Lewis River Valley is followed down to Whitehorse. The glacial features of the valley are very interesting.

The river trip from Whitehorse to Dawson down the great Yukon River offers many problems for discussion, among them those of peneplanation (the river passes through a typical one), the cause of the absence of glaciation north of the Rink Rapid, and the origin of the huge trough in which the river flows, often sunk for thousands of feet below the bordering uplands. Twenty-three days.

C 8.—Vancouver Island Excursion.

This excursion will occupy two or three days, and will include a visit to Victoria and an examination of the coal fields of Nanaimo.

Excursion to Fort McMurray or Athabasca Lake and Peace River.

The route of travel would be from Edmonton to Athabasca Landing. From Athabasca Landing down Athabasca River to Grand Rapids. From Grand Rapids to Fort McMurray. From Fort McMurray the excursionists, if deemed advisable, could be taken by steamer down the Athabasca River to Athabasca Lake, and up Peace River to Vermilion Falls, also along Athabasca Lake and down Slave River to Slave River Rapids. (Thirteen days.) Economic interest in this trip centres largely in the area of Tar Sands along the Athabasca River. Sections of Cretaceous rocks, often continuous for miles, are exposed along the upper parts of both rivers, and flat-lying Devonian limestone in the lower parts.

OUR EUROPEAN LETTER

Spasmodic revival in Siberians — Rand settling down to an investment level — Giesecke mill — Life of the Rand — Report of Inspector of Scottish Mines —Overwinding appliances — Shaft-sinking by freezing.

(Exclusive correspondence to the Canadian Mining Journal.)

London, July 30, 1911.

A spasmodic revival in Siberians emanating from Paris has been a feature of the half-year, but this movement has since subsided. Favourable developments have given a stimulus to the Barriers, otherwise base-metal stocks have been more or less neglected. Interest in Australians, too, has been practically dormant, apart from the Waihi collapse, and the same may be said of Mexican mining shares, though in the latter direction Paris has been a ready supporter.

Oil, as your correspondent has said, is equally idle, the public continuing apathetic and inside support being weak.

The gradual settling down of the Transvaal to a steady investment level is perhaps fully in accordance with the tremendous development that is taking place there. Reference has been made in these columns to the Giesecke mill which is doing such good work at the Geldenhuis Estate section of the Geldenhuis Deep. Experiments with the Bubola patent are also proceeding on the Stanhope area. This plant consists of a large tank, at the bottom of which the cyanide solution is let in by a pipe which is charged with positive electricity. A slight way up the tank is a grating, the use of which is to conduct the electricity over or through the entire mass of sands. At the top of the tank are two stirrers charged with negative electricity, and these work with a planetary motion. At the first test the boiler broke down before the experiment was completed, and work is delayed until the boiler is again passed for service by the Government Boiler Inspector. Triple tests were taken of the charge which averaged 3.5 dwts. (pennyweights) gold, and after a short period the residues were brought down to 0.6 dwt. Acceleration in recovery is one of the principal advantages claimed. The patent rights are owned by a small syndicate, and there have been dealings in the shares, which have a nominal value of $5, at $100 each. Some influential people have been purchasing shares between $50 and $75. The results of the more extended experiments are being awaited with considerable interest. This is, of course, not the first time that electricity has been used in connection with cyanide, and on the Rand there have been applications of the principle several years ago.

Going back to the Giesecke mill it is stated by the manufacturers that the capital cost with a capacity equal to 50 to 60 stamps plus tube mills is about $30,000. To this would have to be added cost of erection, motive power, etc. Roughly speaking, then, for $50,000 a company would have a crushing plant, and to this would have to be added cost of cyanide equipment. C. O. Schmitt, in his paper on "Future Economies in Rand Reduction Plants," estimates the cost of additional reduction plants at $1,000 per ton milled per day, including cyanide equipment. A plant capable of crushing and cyaniding 500 tons per day on the present style would therefore cost $500,000. Rough figures like these—of course, cyanide plant cost must be added—give some indication of the value of the Giesecke mill and its possibilities, providing it is capable of doing what is claimed for it.

Dr. F. H. Hatch, speaking to the Institution of Civil Engineers in London on June 28th, detailed some calculations he had made to estimate the production of gold to be expected from the main reef series of the Rand, if worked down to a vertical depth of six thousand feet. He estimated that at the present time there remained $5,230,000,000 of gold, which, on the basis of an average output of $150,000,000 per annum, was equivalent to a life of 35 years — namely, down to a vertical depth of 6,000 feet. But if, at still greater depths, the banket should contain sufficient gold to yield a profit, after deducting the cost of working, they may rest assured that it would be worked. What, then, were the limiting factors? They were generally considered to be (1) the mechanical difficulty of raising the ore to the surface from such great depths, and (2) the effect of the temperature gradient.

With regard to the mechanical question, the electrical transmission of power applied to stage-winding had so modified the mining engineer's conception of the depth from which deep hoisting was practicable that it was now generally assumed that there were no mechanical difficulties that could not be overcome if

paid to do so. For all practical purposes, the whole uestion turned solely on the gold eontent, and what hat might be at a vertical depth of 7,000 or 8,000 et no one eould tell. This much, however, might be id: the geological strueture of the country clearly dieated the continuance of the conglomerate or ban- et beds to still greater depths than even 7,000 or ,000 feet before the bottom of the great synelinal asin of the Witwatersrand was reaehed; and beyond hat point, the beds must still eontinue until they rose o form the southern lip of the basin known to exist eyond the Vaal River.

For some time past rumours have been reported ere to be in circulation in Rand mining and engineer- ng eireles relative to defeets which have developed n the battery of the City Deep. In this mill the ferro- oncrete system was adopted, but the results cannot e claimed to be satisfaetory, and the absence of elas- icity is a great drawback. The ordinary type of mill, with wooden King posts, absorbs the impact of the eavy stamps upon the rock. The steel concrete King osts at the City Deep are reported to be giving eon- iderable trouble. The whole plant has been reported pon by Mr. Templer, engineer of the Ferreira, and t is stated in eireles usually well informed, that a con- iderable expenditure will have to be ineurred in order o make the plant thoroughly servieeable. An amount f $850,000 is spoken of, but, inasmueh as a 200- tamp mill — that is, the battery itself, and exclusive f tube mills and eyanide plant — could be erected or about $425,000, it is presumed that this figure in- ludes expenditure in providing additional stoping faces so that the 200 stamps can be properly supplied with ore.

Returning to home topies more particularly, there have been a great many diseussions of the report for 1910 of the Inspector of Seottish Mines — more espe- ially in conneetion with the winding accidents report- ed there. The number of shaft accidents seems to be on the inerease, and the new Mines Bill takes cog- nizance of this fact by providing that a device shall be attached to eaeh winding engine whieh shall pre- vent overwinding or overspeeding. Too often aeci- dents, more or less serious, whieh may or may not have a fatal termination, are caused by a lapse on the part of the engineman. He may be seized with illness, he may forget to stop the engine at the proper moment, or he may start it running in the wrong direetion with equally undesirable results.

Experienee has elearly demonstrated the fact that some deviee must be provided, whieh will operate quickly and effieiently in an emergeney. It must also be quite independent of the human faetor, simple in construetion, and meehanieally perfeet. Such an ap- paratus must, at the moment of need, shut off the steam and apply the brake without an undue strain on the engine. It must act promptly, and be free from eomplicated or delicate parts, whieh might fail when a strain is put upon them.

A eontrolling deviee which claims to fulfil these requirements has been placed upon the market by a Wigan iron company. It takes up a floor space of about 6 feet by 1 foot 6 inches, whieh permits of its being plaeed in any convenient location near the en- gine. Its employment renders unneeessary the use of detaching hooks, whieh have been found by mine managers to be unsatisfaetory in the practieal working of colliery winding gear. It will perform three dis- tinet operations: (1) Prevent overspeeding of the en- gine, (2) prevent overwinding, and (3) stop the en- gine if it is started working in the wrong direction. It can be adjusted to accomplish the two latter within about 2 feet of the regular working limit.

The principal part of the device eonsists of a sub- stantial leading screw driven by a chain and sprockets from the main shaft of the winding engine. On this travels — one way or the other, according to the di- rection of the engine's rotation — a square bloek. Im- mediately above it is a notched bar eontrolled by a governor. It is kept raised above the bloek when the speed is normal, but lowered when the speed becomes excessive. When lowered the notched bar is earried along with the block and puts into action a trip at- tachment which turns off the steam at the main valve and applies the brake forthwith. At either end are notches cut successively lower, so that if the end of the wind be reached, even without the speed having exceeded the normal limit, the bar and trip action operate at once and prevent over-winding. In the same way a wrong start in either direction will be im- mediately checked and the cage stopped before dam- age is done. After the controller has acted it ean be reset with a spanner. These eontrollers have been in use at important collieries in England and Wales for nearly two years.

The freezing proeess of shaft-sinking is eomparatively new so far as this country is eoneerned, although a good deal of work has been done with it in Ger- many, that home of the scientific treatment of indus- trial methods. The objeet, of course, is to freeze wet ground so as to prevent or restriet the influx of water, to harden the ground so that mueh timbering becomes unnecessary, and to facilitate the erection of the lin- ing. Some doubt has been expressed as to the depth to which freezing can be earried, beeause, as is well known, the melting point of ice falls as the pressure inereases. J. Riemen has stated that at about 650 feet depth the ice beeomes too plastie to withstand the pressure, but in a paper read before the North of Eng- land Institution of Mining and Mechanical Engineers, W. B. Wilson pointed out that at Easington in this eountry a depth of 615 feet had been attained without the iee showing any signs of plastieity, whilst at the Deutseher Kaiser Colliery in Germany a depth of no less than 1,366 had been frozen, and the ice was hard and brittle. The explanation whieh suggests itself is that a good deal depends upon the distance to which freezing is earried from the side of the shaft. The outer layers of ice will be exposed to the full earth pressure and may be plastic, but they will partly pro- tect the inner iee at the shaft faee, so that with a deeply frozen ground the face should be relieved of mueh of the pressure. In this conneetion it should be remembered that water expands on freezing, so that eaeh outer layer of ice as it forms tends to hold the ground off from the inner frozen ground.

A NEW PROVINCIAL GOVERNMENT CHEMICAL LABORATORY IN MONTREAL.

With the object of encouraging and helping the development of the mineral resourees of the Province of Quebec, the Honourable Mr. C. R. Devlin, Minister of Colonization, Mines and Fisheries, has eoneluded an arrangement with the corporation of the Polyteelnic School of Laval University, whereby in future the ehemical work of the Government will be done in the laboratories of this institution.

Prospectors and miners wishing to ascertain the value of ores and minerals can get assays, analyses and determinations of samples and specimens made at greatly redueed rates, and the well-equipped laboratories, as well as the staff of trained chemists, ensure prompt and reliable results.

Assays — for gold and silver — for copper — for iron, in specimens from the Province of Quebec, will be made for $1 each. The tariff of analyses of other substances is equally low.

If the interested finder of a mineral wishes only for the determination of a specimen, a report, giving name of mineral. its composition and possible commercial value will be sent upon the receipt of a nominal fee of 25 cents.

Copies of the tariff of the analyses of the various substances, with instructions how to sample a mineral deposit in the field so as to obtain the most reliable results in the laboratory, can be obtained by applying to the Provincial Laboratory, Polytechnic School, 228 St. Denis Street, Montreal, or to the Superintendent of Mines, Parliament Buildings, Quebec.

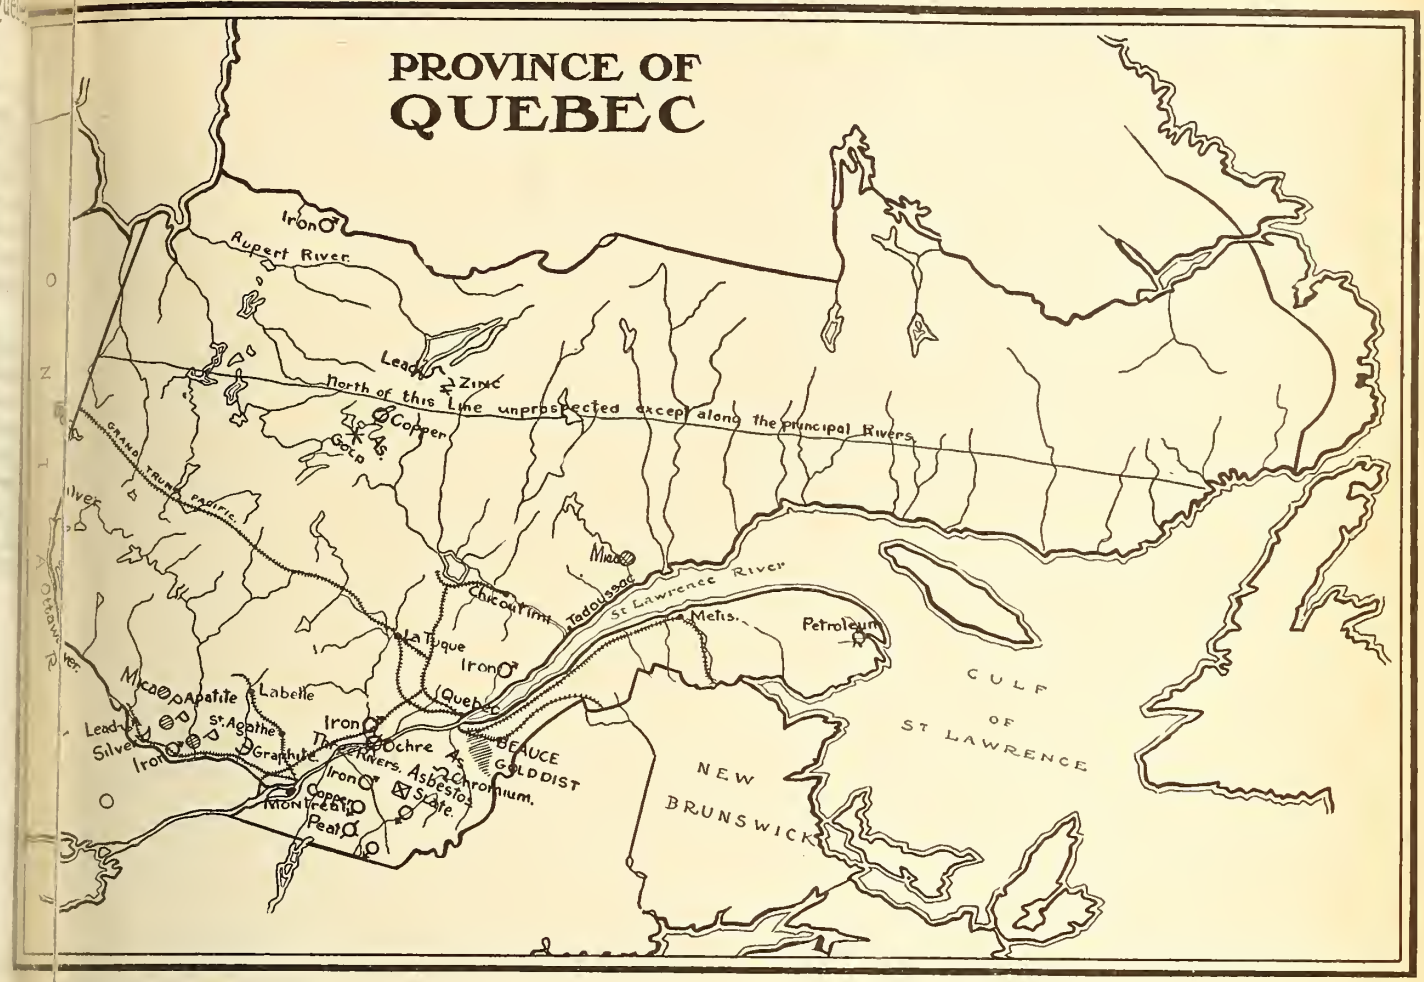
Mining News from Quebec.

(Special Correspondence.)

In the Eastern Townships of Quebec an unprec dented activity in mining is now reported. On th historic Seigniory of Rigaud - Vaudreuil the Dominio Gold Fields, Ltd., has taken over mining rights. Th photograph that accompanies this article shows tha company's elevator and stacker, the first of its kin in Canada. The complete plant is now in operatio Mr. J. R. Duckett, Beauceville, is the managing direc tor.

At Weedon, about 30 miles north of Sherbrooke, o the Quebec Central Railway, the East Canada Smel ing Company is working the MacDonald mine. Thi new field is similar to the well known Eustis deposit which have been worked for a long time by the Genera Chemical Company. The deposits of iron pyrites, wit which is associated copper pyrites, are in a belt tha extends through Weedon and Stratford township Mr. Leland D. Adam is superintendent of the Mac Donald mine.

Elevator and Stacker, Dominion Gold Fields, Ltd.



Mr. B. J. Bennett has been appointed manager of the new asbestos company that has recently acquired the old Ward-Ross mine at Thetford. The price paid was $710,000. A mill is under construction and the mine is being equipped.

* * * * *

The Quebec Mines Branch, of which Mr. Theo. Denis is superintendent, has been most active this year. Dr. J. A. Bancroft, a shining light in the younger firmament of geologists, is striving with the geological problems of the Kewagama and Keekeek Lake regions. Professor Dulieux is investigating the deposits of titaniferous iron ores in the lower St. Lawrence region of the province. He has already finished the examination of the St. Urbain deposits, which were worked 40 years ago. At present Professor Dulieux is working over Seven Islands, 300 miles below Quebec, where exist large bodies of titanium-bearing iron ores.

* * * * *

The Quebec Provincial Laboratory has been transferred to the Polytechnic School, Montreal.

A CANADIAN TALC MILL

(Written for the Canadian Mining Journal.)

Three years ago there was no such thing as a talc-grinding mill in Canada. Shipments of crude talc were made from Madoc, Ontario, to the extent of between 1,000 and 1,500 tons annually. The grinding and marketing were done in the State of New York. As the profits on mining were low, the greater profit accrued to the New York mill owners.

Early in the year 1908, Mr. G. H. Gillespie, a Scotch mining engineer, took in hand the enterprise of equipping a suitable mill for grinding the Madoc talc. It took many months of trial and disappointment to hit upon the proper machinery. The question of grading for the market also gave trouble from the first. Both machinery and grading problems were solved, or, rather, are in constant process of solution. The main drawbacks were overcome early in the game.

The original building selected for the mill was an old, extremely substantial, warehouse, situated a few feet from the Grand Trunk Railway, and almost opposite the station. Alterations were effected and grinding machinery installed. Needless to say, the market had already been as closely investigated as circumstances would permit, and it was known that a foothold could be secured.

In the two photographs that accompany this article, it l be noticed that the mill consists of one large main tion, on lower ground, facing the track. The loading ite can be seen plainly. This building is the original rehouse. The large addition behind and all the aller accretions represent the growth in three years. e mill has grown with the business.

At first the total capacity of the plant was about five s of ground talc per day. The capacity now reaches tons per diem. Even this will have to be enlarged.

In grading, the finished products cover a very wide ge, all the way from material that soothes the irate ant to stuff that goes into the coarsest roofing. And s is the secret of commercial success—a system of ading that eliminates waste.

The amount of hard missionary work that was neces- y to break into the market was a very painful sur- ise to those interested. Once, however, the Madoc talc ame known, the obstacles of competition were not nd to be insuperable. At present Canada sends talc various grades to Great Britain, Europe, United ates, and even farther afield. In three years the larg- talc-grinding industry in the world has grown up nost unsuspected.

A rough flow-sheet, suggestive rather than exact, is en herewith. The massive talc is brought through

cessive stages of comminution until the finest possible sh is reached. Observe, when next the barber decor- es your face with talcum powder, the fineness of the bdivided material. The chance is fair that the com- rting stuff was once handled as ore at Madoc.

Virtue is its own reward. The conscientious reader of the *Canadian Mining Journal* will find in that invaluable paper, in the November 1st, 1907, issue, an article describing the Henderson talc mine—the mine from which comes all the ore supplies for Mr. Gillespie's mill. The mine is under the supervision of Mr. Stephen Wellington, a mining man who has contributed not a little to the development of mining in Eastern Ontario.

Mr. Wellington possesses the mining sense. He knows every outcrop of anything for miles around the country in which he operates.

From the aforementioned back number of the *Journal,* the following descriptive sentences may be quoted:—

"The shaft is 105 feet deep. It bottoms in clean "granular massive talc. Neither hanging nor foot wall "is visible to the deep, where the shaft is 25 feet wide "by 30 feet on the strike. . . . The shaft, or pit, "as it is more properly called, now opens about 40 feet by "35 feet at the mouth, and narrows down irregularly "to the bottom measurements mentioned before. . . . "The maximum width of the vein is about 36 feet. "This measurement is obtainable near the surface, "where, in the pit, the walls are visible. The strike is "north, 40 degrees west. The talc vein cuts across a "tilted deposit of dolomitic limestone. The dip is 80 "degrees south."

The above paragraph was written before the milling enterprise had been attempted. Since then a new, excellently-timbered, shaft has been sunk, and some hundreds of feet of underground work have been done. The amount of talc in sight is enormous. The principal difficulty in estimating it is in keeping within reasonable bounds. Hence the Madoc mill is in the enviable position of having an assured supply for an indefinite period.

A large and cheap supply of ore is not the only advantage that Madoc offers. Cheap hydro-electric power is used at the mill. This implies cleanliness and economy.

HE UNDEVELOPED IRON RESOURCES OF CANADA

By A. B. Willmott, Toronto, Ont.

Abstract of paper read at the Annual Meeting of the Canadian Mining Institute, Quebec, 1911.

We may now fairly assume that the iron and steel dustry is firmly established in this country. Although e steel companies are quite willing that the bounties ould be continued, it is evident from their prosperity at this continuation is not necessary. We may also firm that the system of giving direct grants to en- urage the establishment of basic industries in our country has been fully justified. These bounties have been paid for a term of several years, decreasing in amount each year, and finally terminating on December 31st last. Table 1 shows that the production of pig iron has steadily increased both in tonnage and value.

TABLE 1.

Annual Production of Pig Iron by Provinces, 1887-1909.

Year	Nova Scotia. Tons.	Nova Scotia. Value $	Ontario. Tons	Ontario. Value $	Quebec.		Total.	
1887	19,320	$ 250,000	.....	.....	5,507	116,192	24,827	366,192
1892	40,049	583,556	.....	.....	2,394	53,865	42,443	673,421
1897	22,500	230,000	26,115	$ 291,466	9,392	217,235	58,007	738,701
1902	237,244	2,477,767	112,688	1,584,273	7,970	181,501	357,902	4,243,541
1907	366,456	4,211,913	275,459	4,581,309	10,047	232,004	651,962	9,125,226
1908	352,642	3,554,540	271,484	4,385,271	6,709	171,383	630,835	8,111,194
1909	345,380	3,453,800	407,012	6,002,441	4,770	125,623	757,162	9,581,864

From Table 2 it further appears that there has been an equally encouraging increase in the production of steel.

TABLE 2.

Annual Production of Steel Ingots and Castings 1897-1909.

Calendar Year	Short Tons.
1897	20,608
1902	203,881
1907	706,982
1908	588,763
1909	754,719

It must further be noted that we have made some small exports of both pig iron and steel.

To those who have not considered the subject it will perhaps be a matter of some surprise to note that Canada now ranks eighth among the nations of the world in her production of iron and steel. We have still a long distance to go, however, before overtaking the seventh country on the list, namely Belgium, as shown in Table 3 below.

TABLE 3.

Production of Pig Iron in the Principal Countries of the World.

	1908	1909
United States	16,191,907	26,209,677
Germany	11,805,321	12,625,575
United Kingdom	9,202,280	9,819,469
France	3,400,771	3,544,638
Russia	2,800,653	2,871,332
Austria-Hungary	1,518,549	.....
Belgium	1,270,050	1,632,350
Canada	572,290	686,893
Swedeu	567,821	443,000
Spain	403,554	.....
Italy	112,924	207,800
China	66,409	74,000
Japan	45,396	.....
Australasia	30,393	.....

Notwithstanding this gratifying increase in our production of iron and steel we are still very far from meeting our own requirements. Our imports of manufactured iron and steel goods are still enormous, as shown in Table 4.

TABLE 4.

	1908	190
Imports of iron and steel subject to duty	$51,485,456	$33,08
Imports of iron and steel free of duty	10,334,242	7,31
Total imports	$61,819,698	$40,39

Many of these articles are highly manufactured we can hardly expect that their production should undertaken in Canada. The weight of these iron steel manufactures is largely unknown. Included, h ever, in the figures presented in Table 4 are a la number of partially manufactured products wh could be well made in Canada and of which the t nage is known. These are given in detail in Table

TABLE 5.

Imports of Some Iron and Steel Products of Wh the Quantities are Available.

Material	12 months ending Mch, 1908 Short tons	12 mo endi Mch, Short
Pig iron	212,290	58
Ferro-products and chrome steel	17,661	13
Ingots, blooms, billets, puddled bars, &c.	21,222	8
Scrap and scrap steel	69,213	26
Plates and sheets	126,172	101
Bars, rods, hoops, bands, &c.	98,631	69
Structural iron and steel	373,871	162
Rails and connections	52,706	32
Pipes and fittiugs	25,090	18
Nails and spikes	2,741	1
Wire	57,046	39
Forgings, castings, and manufactures	22,357	13
Total	1,079,000	545

Although a study of Tables 1, 2, and 3 shows t the production of iron and steel is firmly establish it must be admitted that there are some discourag features in the situation. Of the total quantity of required for Canadian furnaces in 1909, only 17 p cent. was of Canadian origin. All the furnaees in O tario and Quebec are dependent on imported coal coke, and two of them are using imported limesto As Ontario and Quebec are devoid of coal, the imp tation of fuel must be continued until such time as further development of the electric process of sm ing will enable us to substitute water power for a p tion of this fuel. These facts are unpleasant; but th should be faced and a serious attempt made to deve our own resources.

A study of the last available statisties shows t iron ore was produced in 1909 in only two of our p vinces, as shown in Table 6.

TABLE 6.

Production of Iron Ore by Provinces, 1908-9.

Provinces	1908 tons	1908 value	1909 tons	1909 val
Nova Scotia	11,802	$ 17,620	.....	.....
Quebec	10,103	22,094	4,150	5,
Ontario	216,177	528,475	263,893	653,
	238,082	568,189	268,043	659,

In 1910 conditions were somewhat improved by small production in both New Brunswick and No Scotia. Our steel industries in Nova Scotia utili nearly altogether iron ore from Newfoundland.

ast a considerable tonnage of ore has been raised Nova Scotian properties; but the cheapness of Newfoundland ores has virtually excluded the Scotian ore from the market.

Ontario and Quebec our furnaces have been sup- in part from Ontario ore and to a small extent Quebec ores; but much more largely by American om the Lake Superior region. This has been part to the cheapness with which American ores be secured, since they are not subject to an im- ax. It should further be noted that American oducers are willing to take contracts for the re- nents of the furnaces and to deliver ores of the ard agreed on. So far there have been practi- no producers of Canadian ore and those who offering to deliver ores were undertaking the ss in a most half-hearted way. Few of them were o accept any considerable contract and from the ness of their operations furnace men were afraid trust them with contracts. Moreover, the ore ced was apt to vary very much in grade and was ently not of an attractive character.

he of the iron and steel companies have been active in looking for Canadian ores and have large sums in the search. It must be confessed o far the results have been rather disappointing. companies have done little in this respect, prob- for the reason that their capital was required in ction with their iron and steel plants. Practi- no money is being spent in Ontario by independ- e companies, a fact, no doubt, partially attribut- o the smallness of the market. While there was y of 40 cents a ton on Canadian ore entering the ican market a producer of Canadian ore had few furnaces with which he might market the ore. Owing to the different grades required by the ent furnaces, and geographical conditions, it of- appened that only one furnace was available. It t surprising that miners have hesitated to em- in the production of iron ore with such a small et open to them. With the reduction of the ican duty to 15 cents a ton this cause is partially ed.

a number of the provinces there are no smelters, iron ore unless within reasonable distance of a ce is of no value. This observation particularly s to British Columbia, where a number of pro- g deposits are known, but where there is no in- e to development because of the lack of a mar- This is also true, though to a much lesser extent, e prairie provinces.

British Columbia.

roughout the coast region of this province nu- us deposits of magnetite are found which are in iron and low in phosphorus. These deposits at the contact of igneous intrusives with some entary rock, usually limestone. These deposits ery irregular in their outcrops and one cannot ct anything definite as to the size and shape of re bodies. They belong to deposits of the peg- e type and presumably have a greater extension pth than they have in either breadth or length. ully a series of outcrops is found along the line of ct varying from a few square feet in area up to sits one hundred and fifty feet wide and several red feet in length. Little is known as to their h, though several deposits have been opened by ls to a depth of one hundred feet. At the Paxton on Texada Island, the ore is exposed by a tun- nel for a width of seventy-five feet, at a depth of about five hundred feet from its highest outcropping on a hill above.

Most of these deposits carry a little sulphur in the form of pyrite or chalcopyrite. In many cases deposits of this type have sufficient copper value to make them attractive from this standpoint and they are operated as copper properties. With the increase in copper there is usually a decrease in iron contents. There are many deposits throughout the coast region too low in both copper and iron to be worked for either.

A long list of these properties is described in the various reports of the Minister of Mines for British Columbia; particularly in that for 1902. Lindeman describes a number of the more important ones. Among these may be mentioned the deposits on the Gordon River, Texada Island, Campbell, and Nimpkish Lake.

The average of all analyses on one of these groups of claims made by the writer yielded iron 56.135 per cent., sulphur 1.34 per cent., phosphorus .101 per cent. On another property the analyses averaged 60.98 per cent. in iron, 1.8 per cent. in sulphur, and .015 per cent. in phosphorus. The average of all analyses in three other private reports on different properties was as follows: iron 62.82 per cent., sulphur 1.54 per cent., phosphorus, .028 per cent.; iron 68.79 per cent., sulphur .35 per cent., phosphorus .056 per cent.; iron 61.47 per cent., sulphur. 67 per cent., phosphorus 021 per cent. The average of these different properties will probably fairly represent this class of ore. The average is iron 58.04 per cent., sulphur 1.14 per cent., phosphorus .044 per cent.

It is estimated by Hayes that these deposits contain at least thirty million tons of ore of present commercial grade and probably a considerably larger amount of low grade and deep ore not now available. My own opinion is that considering the frequency with which this type of deposit has been found in the small area of the province which has been prospected that the total tonnage ultimately available will be much larger than this estimate. Practically only portions of Vancouver and Texada Islands are included in this estimate. Similar deposits are known in the Queen Charlotte Islands and on the Chilcat River, in the extreme northern part of the province. The main land is also likely to show numerous deposits of this class.

Clay ironstones are known to occur in the Queen Charlotte Islands and on Vancouver Island in connection with the coal deposits; but at present are of no commercial value. Possibly they may be of some use in forming a desirable mixture when the smelting of the magnetite is undertaken. At several points deposits of bog iron ore are known and although very great claims have been made as to the value of these deposits I think they may be considered useless at the present time. Some bodies of hematite are reported on Vancouver Island and on the main land near Bute Inlet, but little is known of them. In southeastern Kootenay, at Kitchener and Bull River, deposits of hematite have been partially explored.

The lack of smelters in British Columbia and the Pacific coast of the United States has been a serious drawback to the development of the British Columbian ores. Without a market the mine owner was not warranted in spending money on the development of his property. Per contra, iron men have hesitated to establish furnaces until a sufficient quantity of iron ore was assured them. The coming summer will probably see an end

of this condition of affairs, as two companies are now proposing to establish iron furnaces in the province.

Prairie Provinces.

Throughout Manitoba, Alberta and Saskatchewan almost no iron ore of commercial value is at present known. Naturally in the prairie parts rocky exposures are few and moreover the conditions for the formation of iron ore deposits are absent. In the Pre-Cambrian area, which touches the north-western corners of Manitoba and Saskatchewan, iron deposits of the Lake Superior type will probably be found.

On the outer edge of the Rockies there are numerous occurrences of reddish shales of Triasic age, which in places carry considerable iron. Possibly some of these may yet prove of value as a source of iron ore.

Alberta, particularly on its west boundary, is very rich in coal of good coking quality. There is a large and ever increasing demand for pig iron in the three provinces for local foundry purposes. Such pig at present commands a very high price, due to the high freight charges on pig iron from the east. There does not, however, seem to be any available source of iron ore within these provinces; but the hematite deposits of south-eastern British Columbia, if properly developed, may yield sufficient ore for a furnace situated in the Crow's Nest Pass.

The iron ores already known, and which may be found, in north-eastern Manitoba and Saskatchewan are too far from a source of coke. With the development of the electro-thermic process for smelting iron ore these may, perhaps, become of value.

The Territories.

In the Yukon Territory occurrences of magnetite similar to those occurring in the coast region of British Columbia are known. Cairnes describes the Mack claim on the Hutshi River as "A small hill of almost solid iron ore about two hundred feet long." The Gilltana Lake claim consists of magnetite, with more or less chalcopyrite, as is so often found with these contact deposits.

On the head waters of the Wind, Bonnet Plume and Snake Rivers, tributaries of the Peel, Camsell describes large quantities of float consisting of banded jasper, with hematite or magnetite. On the Rackla, a tributary of the Yukon, Keele finds similar float in large quantities. Apparently around the head waters of these streams there is a large area carrying banded jaspers similar to the Lake Superior type. The iron ore is of course of no commercial value at present and consequently no exploration has been undertaken.

Several occurrences of magnetite and hematite are reported on the islands of the archipelago in the district of Franklin.

In the district of MacKenzie specular hematite is reported to be found in the vicinity of Great Slave Lake. In the territory of Keewatin, magnetite, apparently of the Lake Superior type, is found near Knee Lake. On Berrens River, a magnetite of similar character is reported by Low. There are probably very numerous occurrences of the Lake Superior type stretching far to the north-west through the province of Keewatin. Close examination has not yet been made of this large area.

On Sutton Mill Lake, an expansion of Trout River, south of Hudson Bay, there is an exposure of the Animikie rocks similar in character to those at the west end of Lake Superior. Dowling reports the occurrence of jaspilite interbanded with hematite and magnetite, as in the region around Port Arthur. The deposit observed by him occurs in narrow beds, the iron running fr[om] 6[5] per cent. down to 28 per cent. It would seem pr[o]bable that careful examination of these areas might lead t[o] discovery of iron ore of commercial value. The d[e]posit is seventy miles from Hudson Bay.

In the territory of Ungava, banded jaspers are k[nown] in considerable quantities, and commercial ore ma[y] be found. Leith, Low, and Mickle, together with o[thers] have visited and described these rocks. The Nast[apoka] group consists of chemical and mechanical sedi[ments] closely related in appearance to the Animikie ro[cks] the Lake Superior basin. Interbedded with the [slates] and sandstones of this group are beds of jaspilite [from] to one hundred feet in thickness. In these bed[s] occasional concentrations somewhat richer in iron[ore]. In the natural exposures few cases are found wher[e] than half of the beds are rock and even of the ba[nds] there is considerable silica mixed with the iron[ore]. There are two types of occurrence, one of siliceous h[ema]tite or magnetite ore, and the other manganiferou[s] bonate ore. In both cases the local enrichment do[es] extend more than a few hundred feet in length or d[ip] dip of the beds. The similarity of geological occur[rence] and of the enclosing rocks on the Nastapoka Island[s] in the Mesabi district of Minnesota is striking. Wh[ether] commercial ore bodies will yet be discovered in t[he] former can only be told by extensive exploration.

One hundred and twenty-five miles south of U[ngava] Bay, in the valley of the Koksoak, there is an occur[rence] of rocks apparently of Animikie age. For seve[ral] miles these rocks are exposed along the river valley [from] Shale Falls to the mouth of Swampy-Bay River. L[ow] describes the ore-bearing portion of these rocks as [alter]nating bands of magnetite and jasper in close prox[imity] to cherty limestone. Analyses of the ore run fr[om] per cent. to 54 per cent. in metallic iron. On the na[tural] exposures from which these samples were taken th[e ore] is hardly of high enough grade to be of comm[ercial] value. Such as it is Low states that "The ore in [sight] must be reckoned by hundreds of millions of tons."

On the Ashuanipi branch of the Hamilton River, [one] hundred miles due north of the Seven Islands, o[n the] north shore of the St. Lawrence, there is an occur[rence] of similar rocks. Through faulting four different [belts] of these rocks are exposed. The ore formation co[nsists] of banded magnetite or hematite, with jasper and c[herty] limestone. Assays of natural outcrops showed [iron] varying from 30 per cent. to 40 per cent. Low [states] that "The deposits are widespread and that the or[e will] be found in practically inexhaustible quantity." T[he] striking similarity of these last occurrences to se[veral] of the iron ranges of the Lake Superior district [must] be noted. Whether natural concentration of these [ores] has taken place can be proved by careful explor[ation]. The large area over which the occurrences are f[ound] renders it probable that in some cases concentration [will] have occurred.

On the Stillwater River, in Ungava, Low repo[rts] large area of iron-bearing ore in gneiss. Beds of in[ferior] iron ore are also reported from the shore of Hu[dson] Strait.

Ontario.

The iron ores of Ontario have been the subje[ct of] numerous papers and for that reason only a brief [sum]mary will be given here. From the standpoint o[f the] present demand for iron ore the deposits of Ontari[o are] the most important in the Dominion and consequ[ently] are not receiving the space in this paper which [their] commercial importance would warrant. A consider[able]

more remote portions of the Dominion has, how- taken so much time that I shall content myself y referring the interested readers to other papers. eleventh volume of the journal of this institute, ished a paper on the iron ores of Ontario, which rized fairly well the known occurrences of iron Ontario. To those seeking more detailed informa- would refer to the index to the reports of the u of Mines of Ontario, 1891-1907.

Iron ores of the magmatic type are represented in On- by deposits at Nemogosenda, on the Canadian Railway; at Bushnell, on the Temiskaming and rn Ontario Railway; at Gooderham, on the Iron- Baneroft and Ottawa Railway, and elsewhere. All se ores are magnetite and most of them are con- ted with more or less titanium and frequently ulphur. That at Nemogosenda has been worked ar, and some others have been worked in the past. yrrhotite of Sudbury, which carries the Ontario belongs to this type.

The Pegmatite type is represented by such properties Belmont, in Central Ontario. This is a magnetite, phosphorus, high in iron and with some sulphur. nber of deposits of a similar type are known h Eastern Ontario.

The Vein type is represented by a number of small nimportant deposits occurring in the quartzites lower Huronian, north of the Georgian Bay. De- of this kind are known in Aberdeen Township, Algoma Mills, and in the vicinity of Killarney.

The Carbonate type is represented by the siderite of ian age occurring on the Opazitika, in Northern o. Deposits of siderite of Keewatin age are found Helen Mine, Josephine Mine, Magpie Mine, in chipicoten district, and at Steep Rock Lake, in the River district. These siderites run around 35 per n iron, are very low in phosphorus, and with some r. They exist in considerable amounts and on g would yield a fairly good ore.

The most important ores of Ontario belong to the Lake or bedded type. They are restricted almost en- to beds of Keewatin age and occur at scores of throughout the province from the Manitoba ary to the Ottawa River. The different ranges been described by Miller, Coleman and Willmott, an, Miller, Leith, Smith, Bell, Silver, Coleman, an and Moore, MacKenzie, Moore, Allen. The for- consists of chert or jasper interbanded with te, magnetite, siderite, or pyrite. These beds are standing vertical and their total length within province must amount to several hundred miles. The ity between these ranges and the Vermilion iron of Minnesota is very close. Natural concentra- re to be looked for in these iron formations, and e, if found, will likely be deep. Comparatively xploration has yet taken place on these Ontario . It is probably safe to assert that there has been xploration on the twenty-three miles of the Ver- iron range than on the several hundred miles in o.

There are four producing mines in Ontario located s class of deposit, namely: the Helen, Magpie, an, and Moose Mountain mines. At least three properties have been drilled, with satisfactory re- but have not yet been opened up.

Limonite type is represented by a number of bog eposits in the older parts of the province, which een slightly exploited in years gone by. Some de- posits of this character in the Metagami Valley are the subject of a paper before the institute this year.

The Metamorphic type is represented by many of the magnetite deposits along the Kingston and Pembroke Railway, which have been described by Ingall. Other deposits of this character have been worked along the lines of the Central Ontario Railway and the Iron- dale, Baneroft and Ottawa Railway.

Quebec.

Iron ores of the Magmatic type are of frequent occur- rence throughout the province of Quebec. Deposits at Bay St. Paul, Seven Island, St. Jerome, St. Lin, Lake Kenogami, and on the Chaudière are described by Ellis. Many of these deposits are of large size and some of them are high in iron, all of them carry titanium and many of them in large amounts.

Deposits of the Beach Sand type are also of frequent occurrence in the province. They are particularly abundant along the shores of the St. Lawrence, where they occur in beds from six inches to two feet in thick- ness. Among the more important are those at Moisee, Mingan, Bersimis, Tadousac, which are described by Ellis.

Bog ore deposits are widely scattered throughout the province, and have been mined in small quantities for many years. In the district of Three Rivers small fur- naces have been at work for a long time using the local ore supplies. Bog ores have been mined in Drummond and Vaudreuil Counties.

Ores of the Lake Superior bedded type do not seem to have been recognized to any large extent. Their occur- rence has been noted on Lake Opazitika, on the boundary between Ontario and Quebec, and also near Lake Megan- tic, in the south-eastern corner of the province. As there are numerous areas of the Keewatin rocks through- out Quebec (usually mapped as Huronian in the Geological Survey reports) there is every reason to think that with proper prospecting many occurrences of this type will be found.

Ore of the Pegmatite type is found at a number of places, particularly in the counties of Pontiac and Ot- tawa. The Ironside Mine and the Bristol Mine have both produced a small amount of magnetic ore. Throughout the Eastern Townships a number of magne- tite deposits are known in the townships of Brome, Sut- ton, St. Armand, and near Sherbrooke. These prob- ably belong to the Metamorphic type.

A number of deposits of chromite are known in the Eastern Townships and some production takes place an- nually. They have been described by Cirkel.

New Brunswick.

During 1910, iron mining in New Brunswick has taken on a new lease of life. This is due to the discovery and exploitation of some large deposits of iron ore near Bathurst by the Canadian Iron Corporation. These ores were described by Hardman before the institute two years ago. There are three separate areas, one of them two thousand one hundred and forty feet long proved to a depth of five hundred feet by drilling. Mr. Hardman estimated that half of these beds would aver- age 53 per cent. iron and not over 15 per cent. silica; phosphorus would be high, possibly .75 per cent. The second area after hand sorting was expected to yield a product 58 per cent. in iron, 10 per cent. silica, 0.88 per cent. phosphorus, and 0.055 per cent. sulphur. During the past year the property has been opened and machin- ery installed for the production of one thousand tons

of crushed ore per day. A railway has been built and a dock completed at Newcastle, New Brunswick. Seven thousand tons of ore were shipped before the close of navigation. This ore belongs to the Lake Superior bedded type and seems closely related in origin to the deposits at Moose Mountain and Atikokan, Ontario.

Years ago some iron ore was mined in the county of Carleton and smelted locally. The ore is a hematite, occurring in numerous veins, one to sixteen feet in width. The ore was very low in iron and high in sulphur and phosphorus, and the enterprise failed. Some small deposits of hematite are known in St. John County and some magnetite deposits in St. John and Carleton Counties. These latter deposits have been described by Bailey. Bog ore is of frequent occurrence throughout the province, but is not at present utilized.

Nova Scotia.

Years ago Nova Scotia produced considerable iron ore; but the output diminished until it reached the vanishing point. Last year, however, witnessed a moderate revival of shipments. This decrease has been due to the ease and cheapness with which our eastern steel plants can procure suitable ore from Newfoundland.

The iron ores of Nova Scotia have been the subject of an exhaustive monograph by Woodman, published by the Mines Branch of the Department of Mines at Ottawa. According to Woodman, the Nictaux-Torbrook Basin is the most important and promising field in the province. The ores are Clinton hematites, and bedded magnetites metamorphosed from it. The ores occur in two zones striking north-east. On the north one are two ore bodies, the Leckie and the Shell, of economic value. The ores run 44 per cent. to 49 per cent. iron, 15 per cent. to 17 per cent. insoluble, .7 per cent. to .9 per cent. phosphorus, and sulphur nearly .01 per cent. The ore is used largely at Londonderry for mixing with local limonite and carbonate. The Clementsport district is regarded as a promising field for exploration. In Antigonish County are other Clinton hematites, which may be of value.

Along the Cobequid Hills, in Cumberland and Colchester Counties, there are many isolated localities, in the Devonian, where siderite and ankerite occur. In places these have altered to oxides at the surface, but rapidly changed into the unaltered carbonate in depth. Acadia Mines has been intermittently active for years as a mining and smelting centre. The ore is very low in phosphorus and sulphur and exceedingly low in iron.

Summary.

No estimates of the amount of available iron ore in Canada have been made by any of the various Governmental officials. In a report by Hayes on the Conservation of Natural Resources in the United States, an estimate is made of the iron ores in the countries adjoining the United States. The estimate is there made of available ore as follows: British Columbia, thirty million tons; Ontario, nine million tons; Nova Scotia, four million tons; total, forty-three million tons. This I would consider a sufficiently high figure for ore already known. At the same time the possibilities and indeed probabilities are so great that a much larger tonnage must be considered as likely to be found. The Lake Superior type of bedded deposit is known to occur in the extreme north-west of our country in the Yukon Territory and in the south-east in New Brunswick, a distance of twenty-eight hundred miles. At numerous points between these extremes, Keewatin rocks of the great Archæan shield are known to occur, and in every case where these have been carefully searched for iron formation has been found. In far from all of these occurrences will the iron formation be productive of commercial ore, but we have every reason to believe that with careful and detailed exploration many of them will. It is true that large areas at present are so far from transportation that they cannot be considered as possible sources of iron ore for years to come.

On either side of the shores of Hudson Bay Archæan rocks are found much as they border the sides of Lake Superior. Already, with a most limited amount of exploration, we know that rocks of Keewatin and Huronian age are found bordering the shores of this inland sea and that these series of rocks carry iron formations just as they do around the basin of Lake Superior. Sixty years ago the production of iron ore on Lake Superior in the quantity in which it is produced to-day would have been looked on as an utter impossibility. It was urged that the district was so remote from supplies of coal that the ore even if found could not be profitably smelted. With the tremendous cheapening of transportation this has proved to be a false prophecy, and it is quite possible that water carriage from Hudson Bay may yet solve the transportation problem for that great region. It should further be remembered that Hudson Bay itself is navigable for quite as long a period each year as Lake Superior.

In considering the possibilities of our great northern areas it would be well, also, to bear in mind what has been accomplished in Sweden during the last few years. Some of the largest deposits of iron ore in the world are now being mined in that country within the Arctic Circle. Geologically these ores occur in the Pre-Cambrian rocks found to such a large extent in our own country. The exact equivalent in type of ore deposit is at present not known here; but it is quite within the bounds of possibility that such may yet be found.

The Clinton ore deposits, which yield such a large portion of iron ores of the United States, occur but to a limited extent in Canada, and cannot be looked upon as probable large producers. In Newfoundland, however, two of our eastern steel companies have very large iron ore reserves in beds of this type.

Editor's Note:—In the original paper reference numbers are affixed to each author mentioned. These are omitted in the above abstract.

MINING RIGHTS IN QUEBEC SEIGNIORIES

The last title to a Quebec seigniory was issued in 1762, under the French regime. All mining rights, all except a few seigniories were reserved to the Crown. After the British occupation in 1763, the townships were granted or sold with reservation of mineral rights. Thus, on concessions of lands made before 1763 the Crown still possesses the mining rights; whilst on lands patented between 1763 and 1880 the mining rights belong to the surface owners, except for gold and silver, which were always specifically reserved.

The provision as to seigniories affects 11½ million acres, and hence is of some importance.

SOME COAL MINING DATA

Excerpts from the Provincial Mineralogist's B.C. review of "Coal Mining in the Province."

The following table shows, for the past four years, the output and the *per capita* production of the various districts:—

Year and District.	Gross tons of coal mined.	Total No. of employees at colliery.	Tons of coal mined per employed	No. of men underg'd.	Tons of coal mined per underg'd employee.
1907—					
East Kootenay District	876,731	2,290	383	1,527	574
Coast District	1,342,877	3,769	356	2,862	469
Whole Province	2,219,608	6,059	366	4,389	506
1908—					
East Kootenay District	883,205	2,524	350	1,746	506
Coast District	1,226,182	3,549	345	2,686	456
Whole Province	2,109,387	6,073	347	4,432	476
1909—					
East Kootenay District	923,865	2,427	380	1,737	532
Coast District	1,476,735	3,991	370	2,976	496
Whole Province	2,400,600	6,418	374	4,713	509
1910—					
East Kootenay District	1,365,119	3,111	439	2,374	575
Coast District	1,774,116	4,647	382	3,529	502
Whole Province	3,139,235	7,758	404	5,903	532

It will be seen from the above that the production employee' has materially increased, particularly in last year. This increased effectiveness of the labour loyed is largely due to better methods, better equipt, and greater volume of output.

During the year 1910 there were 404 tons (2,240 of coal mined per employee, or 532 tons for each erground employee. According to the 'Report of the pector of Coal Mines for the State of Washington,' ppears that in the mines in that State there was ed in 1909 3,205,900 long tons (2,240 lbs.) of coal 90,639 tons of 2,000 lbs.), with a *per capita* proion of employee equal to 560 long tons per annum; e in 1910 each employee represented 590 long tons luction, or an output of 3,553,200 tons (2,240 lbs.). m this it appears that the effectiveness of the emee is greater in Washington than in British Colum--whether due to the nature and occurrence of the seams, equipment, or other causes is not known.

It is, however, to be noted that this increased *per ta* production has been obtained at a greater list ccidents than in British Columbia mines, as in hington there was 92,548 tons (2,000 lbs.), or 82,632 of 2,240 lbs., while in British Columbia there was ed some 112,116 tons (2,240 lbs.) for each life lost."

he next table gives analyses of accidents in British mbia coal mines in 1910:—

"The gross output of coal for the year was 3,139,235 tons (2,240 lbs.), which represents an increase over that of the year 1908 of about 48.8 per cent., and over that of 1909—formerly the 'banner year'—of about 30.7 per cent.

"Of this gross tonnage of coal mined, 2,800,046 tons was used as coal, while 339,189 tons was utilized in making coke, of which there was produced 218,029 long tons.

The total value of the product of the collieries of the Province for 1910 was $11,108,335, an increase over the highest previous record—that of 1909—of $2,533,451, or nearly 130 per cent.

"As in former years, the greater proportion of this product was made by three larger companies—the Crow's Nest Pass Coal Co., with two collieries in East Kootenay, and the Western Fuel Co., of Nanaimo, and the Canadian Collieries (Dunsmuir), Ltd. (formerly the Wellington Colliery Co.), both operating on Vancouver island.

"In addition to these larger shippers, appreciable shipments were made by the Hosmer Mines, Ltd., and the Corbin Coal and Coke Co., in East Kootenay, by the Nicola Valley Coal and Coke Co., the Diamond Vale Collieries, and the Coal Hill Syndicate, all of Nicola valley; and by the Pacific Coast Coal Mines, Ltd., and the Vancouver and Nanaimo Coal Mining Co., both operating on Vancouver island, near Nanaimo.

	No. of accidents per 1,000 men employed.				Tons of coal mined per accident.			
	Fatal.	Serious.	Slight.	Total.	Fatal.	Serious.	Slight.	Total.
East Kootenay District	5.46	15.75	5.78	27.00	80,301	27,860	75,840	16,251
Coast District	2.36	9 89	10.32	22.59	161,283	38,568	36,961	16,896
Total Province	3.61	12.24	8.51	24.36	112,116	33,044	47,564	16,610

"During the year 1910 about 51.3 per cent. of the coal, sold as such, produced by the collieries of the Province, was consumed in British Columbia; about 46.2 per cent. was exported to the United States, including Alaska; and 2.5 per cent. was exported to other countries, chiefly to Mexico. Of the coke sold, about 96 per cent. was consumed in British Columbia, and the remainder was exported to the United States." (Note by Ed.—In 1908, 19 per cent., and in 1909, 19 per cent of the output of coke was exported to the United States.

The distribution of this output of coal and coke is shown in the next table, which is followed by another showing the number of employees at the coal mines and coke ovens.

Coal and Coke Produced, Exported, Etc.

Sales and Output for 1910. (Tons of 2,240 lbs.)	Coal		Coke	
	Tons.	Tons.	Tons.	Tons.

The Porcupine Gold Area

(Extracts from report by A. G. Burrows, Ontario Bureau of Mines.)

Character of the Gold-Bearing Deposits.

The occurrence of gold at Porcupine is associated with the quartz solutions which circulated through the fissures in the Keewatin and Huronian series. The irregular fissuring has produced a great variety of quartz structures, varying from the tabular, though often irregular or lenticular, vein which may be traced several hundred feet, to mere veinlets, often only a fraction of an inch in width and a few feet in length, which ramify through a rock that has been subjected to small irregular fissuring. This latter variety is well illustrated in the fissuring of ankerite bands, so characteristic of many of the gold deposits of Porcupine. Irregular and lenticular bodies of quartz often occur which may have a width of ten or twenty feet, which die away in a distance of fifty feet. Again there are dome-like masses of quartz which are elliptical or oval in surface outline, but whose underground extension has not been examined closely. In some parts at least these masses can be seen in contact with underlying rocks at a low angle, which would suggest that they are broad lenticular masses which have filled lateral fissures in the country rock. The most conspicuous dome masses are those of the Dome property where the two largest are about 125 feet by 100 feet. A fissure may be vertical and regular at some points. At others it may incline at a lower angle to the ho-

l or take on a more or less lenticular form.

e relationship of the strike of the veins to that of the nclosing rock is often difficult to determine, since generally along the veins there has been shearing of the country rock which may conform to the general direction of the strike of the veins. However, by determining numerous strikes in the schist away from the veins, it is seen that the majority of them are inclined to the direction of strike of the enclosing rocks. In dip the veins vary from vertical to nearly horizontal. In No. 1 shaft of the Hollinger the vein is practically vertical, while a series of narrow quartz veins, 6 to 18 inches wide on the Lindburg claim, have a dip at the surface of only 20 degrees. The prevailing dip of the schist in the Porcupine area is to the north at high angle, and frequently the veins dip distinctly to the south across the cleavage of the schist. While it is apparent that most of the deformation of the country antedates the vein formation, nevertheless there is a decided tendency in many cases for the fissuring to be influenced by the direction of schistosity, which is also a direction of weakness; hence we find veins having a more or less lenticular structure the strike of which closely corresponds to that of the country rock.

Distribution of Veins.

While gold-bearing veins occur over a wide area and are often isolated, it is seen, from a number of those already discovered, that they occur in groups along certain lines. For instance, in Tisdale Township there are at least three distinct areas where the fissuring has been most pronounced. One such area extends from the southeast end of Miller Lake, on lot 11 in the first concession, in a northeasterly direction for three miles, and includes such veins as the Miller-Middleton, Hollinger, McIntyre, and Connell or Rea, and in addition many others with visible gold. The average strike of the veins here is **northeast-southwest.** Another series, including the Davidson, Crown-Chartered, Armstrong-McGibbon, and Bannerman (in Whitney), occurs in the northeast part of the township in the first concession. The general direction of the veins is east and west. Again in the southeast part of the township is a group including the Foster, Dome, and Dome Extension, with general strike somewhat south of west. Similar groupings could be mentioned in other parts of the area.

In these disturbed zones the country rock is generally schistose in character. At the Dome mine the disturbed area has a width of about 600 feet, in which there are numerous narrow quartz veins in addition to large irregular quartz masses.

Well defined, disturbed zones occur in the fifth concession of Tisdale. In this locality the main rock is a light greenish, fine-grained. rather massive greenstone. This greenish rock is itself not much fissured, but here and there through it are bands of rusty-weathering carbonate, which is generally schistose, striking east and west. I think that much of the carbonate associated with this greenstone is of secondary origin. It is possible that the shattering and fissuring of the greenstone in an east and west direction may have caused a deposition of migrating carbonate solutions, partly filling fissures and partly replacing the greenstone. These carbonate bands were later fissured, and gold-bearing quartz solutions deposited in them. The fissuring of the carbonate is generally irregular, and hence we find veins with steep or low dip striking with the schist and across it. This irregular series of veins is seen at the Crown-Chartered and Armstrong-McGibbon properties. Where the veins are small, it becomes necessary to mine both the carbonate and the intersecting quartz veins. Gold often occurs in the carbonate near the contact with the quartz veins, as well as in the quartz.

Distribution of the Gold.

While the quartz is considered to carry the gold, it was noted at many properties that the metal occurs in greatest quantity along certain lines which give a streaky character to the ore. On the surface these streaks are rusty, due to the oxidation of pyrites, while at depth they are dark gray or greenish in colour.

Thin sections of quartz from the main Hollinger vein show grains of quartz with irregular outline, which often contain liquid and gas inclusions. There has also been much secondary pressure, indicated by strain shadows or wavy extinction, and along lines of slip or fracture planes there has been much crushing of the quartz to finer grains. In these crushed areas are secondary minerals like calcite, sericite, etc., while iron pyrites is also present in cubical form and has evidently crystallized, subsequent to the crushing.

Some thin sections from the Rea mine main vein also show much secondary crushing along lines. Calcite and sericite are present in the crushed quartz generally in linear arrangement, and in addition there are several rough crystal outlines of free gold which were formed subsequent to the crushing.

These fine dark streaks may have resulted from a solidification and shrinkage of the quartz forming filmy cracks, which may have become slip or crushing planes along which the richer gold-bearing solutions were deposited at a later period.

These minute dark streaks in the quartz are frequently slickensided, and this character may often be seen in hand specimens, as from the Rea or Vipond mines.

It should be noted that where cracks or fracture planes have been produced in a quartz vein and subsequently filled by minerals from solution, secondary quartz can be distinguished with difficulty, if at all, from the original quartz. Hence it is not always possible to say whether visible gold in such a vein occurs in the original or in secondary quartz.

Carbonates of lime, magnesia, and iron occur with the quartz in practically all the veins in the area. This material may have been absorbed from the wall rock, which is frequently dolomite or rock impregnated with dolomite or calcite. Fragments of country rock are often included in the veins. Veinlets of clear calcite occasionally cut the quartz veins.

The distribution of the gold is generally irregular, occurring along one or both walls, while other portions of the veins may be very low grade. Most spectacular showings occur on many properties, but these are limited to portions of the veins. Considering the irregular character of certain veins and the quantity of country rock which will need to be mined, the ore must be considered low grade

Iron pyrites occurs in massive and crystallized forms, somewhat sparingly in most of the veins. Cubes of pyrites are frequently abundant in the enclosing rocks, especially where sericite or dolomite schist occur. A sample of cube pyrites was separated from the schist, obtained from a shaft of a principal property, and an assay gave a gold content of $10.40 per ton.

Copper pyrites, galena, zincblende, and pyrrhotite are found in some veins in very minor quantity. Sulphide of silver, argentite, occurs in association with the gold on the Powell property in Deloro township.

It will be seen from an examination of the ore from most of the properties that it is largely free milling, while the concentrates should be amenable to cyanide treatment.

Little is said in this report as to actual values of properties, since their sampling is the prerogative of their owners. Many samples were taken for assay, rather for the determination of the distribution of the gold, which was found to be irregular and to be associated with the secondary fracturing of the quartz (and schist) in many cases. The determination of the value of properties is a matter requiring considerable development accompanied by extended sampling and mill tests.

In the following is a brief description of a few of the working properties. Gold has been discovered on many claims, some of which discoveries are of recent date. A part of the coming summer will be devoted to an examination of these properties.

The Dome Mine.

This property, comprising six claims, is situated in the first concession of Tisdale, and includes parts of lots four and five. The main workings are on the northwest forty acres of lot four. In an area, which is roughly 600 feet wide north and south, and 800 long east and west, there are frequent occurrences of quartz in irregular masses and narrow quartz veins, in some of which there is visible gold. Toward the east end of the workings there are large dome-like masses of quartz in contact with Huronian conglomerate and slate-like greywacke, while to the west the quartz occurs chiefly as narrow veinlets associated with Kewatin schist which is impregnated with carbonate. The country rock in the proximity of the veins contains considerable crystallized iron pyrites.

The surface of this deposit was sampled during the summer of 1910, while a part of it was tested by underground workings, consisting of five shafts, one raise, and about 1,000 feet of drifting and cross-cutting at the 40-foot level. In addition, seven diamond drill holes averaging 400 feet tested the property at various points. During the latter part of the summer a 100-pound Nissen stamp was used for sampling purposes. As the result of this prospecting the company decided to equip the property with a modern 40-

pump. The solution will be pumped to triangular precipitating presses, precipitation taking place entirely during the passage of the solution through the pump, pump-column, and presses. The precipitates will be acid-treated, fluxed and smelted.*

West Dome Mines.

This property, commonly known as the Foster, is directly southwest of the Dome in lots five and six. There are several veins on this property, some of which occur near the Dome boundary. These are narrow, averaging possibly two feet in width, and consist of ankerite and quartz. One shaft has been sunk to a depth of 25 feet on a vein which dips about 75 degrees to the north. The greatest attention, however, has been paid to the deposit known as the "Curts vein," which is situated in the southwest part of the property. This vein has been stripped at various points, over a distance of 1,200 feet, showing a width of about three feet up to twenty-two feet. The deposit has well-defined schist walls, and dips steeply to the north. In proximity to the vein the country rock is rusty weathering, but away from the vein is a greenish Keewatin schist. The main mass of the lode is a lime-magnesia-iron carbonate, the composition of which is given earlier in the report. This mass is variously called ankerite or ferruginous carbonate. In fresh material the carbonate has a gray to light bluish colour, but on the surface is much stained to a rusty brown, which has resulted partially from the oxidation of iron pyrites but chiefly from ferrous carbonate. In parts of this carbonate rock there has been fracturing and filling with quartz and a later carbonate. The quartz veinlets vary from mere threads up to two feet in width, the widest of which are mostly transverse to the strike of the lode and end abruptly at the schist walls. Unequal weathering of carbonate and quartz has resulted in a striking ribbed structure. Native gold occurs in patches in the quartz and also in the carbonate near the quartz, indicating an enrichment of the carbonate from the quartz veins. When the property was visited on February 21st the development consisted of only two shafts, which were down 32 feet and 45 feet respectively, so that little was known at that time as to the actual value of the deposit.

The Hollinger Mines

The property consists of four claims lying to the east of Miller Lake in the southwest part of Tisdale. There are a number of quartz veins which have a general northeast and southwest strike. Development has been largely confined to the southeasterly vein of the series, which is generally known as the main Hollinger vein. This vein has the characteristic lenticular structure, which is frequently seen in this area, widening in places to 15 feet and again narrowing to a few feet. Two vertical shafts No. 1 and No. 3 625 feet apart, have been sunk 100 feet. Of these No. 1 is a 14 x 6½ foot 3-compartment shaft, and has been used as the main working shaft. No. 2 shaft, which is midway between the others, was discontinued at 60 feet. No. 1 and No. 3 have been connected at the 100-foot level by a drift along the vein. On February 19th this drift had been extended 300 feet northeast of No. 1 shaft, and at a point 120 feet from No. 1 shaft a 6 x 9-foot winze had been sunk 114 feet. The vein, as exposed at the surface, at the bottom of No. 1 shaft and at the bottom of the winze, is nearly vertical. A cross-cut had also been run from a point 110 feet south of No. 1 shaft 100 feet to the southwest towards the second vein of the series.

The gold in the ore occurs chiefly along dark seams in the quartz in which there is iron pyrites. These seams are well distributed in much of the quartz in this vein. Copper pyrites, zincblende, and galena occur in minor quantity. Other minerals in the vein are calcite, dolomite, sericite, and chlorite. Fragments of wall rock are frequently included in the vein. The wall rock is a grey sericite schist impregnated with carbonate and iron pyrites.

For the past year a 2-stamp Tremaine mill has been treating about 4 tons of ore per day, which represented only a small portion of the ore raised from the mine during development.

Much of the wall rock, which is impregnated with iron pyrites, is said to carry gold values for some distance from the veins. This can be treated with better results by cyaniding.

A mill will be erected during the coming year.

The Rea Mine.

The Rea property consists of two adjoining 160-acre veteran claims in the north half of lots 6 and 7 in the third concession of Tisdale. Several veins, with visible gold, have been discovered on the property, but most of them, beyond stripping, have not been developed. Attention has been chiefly confined to the vein known as the Connell, which is on the lot line between the claims. This vein strikes north 47 degrees east magnetic, and has been traced, partly by trenching in the low ground to the northeast, a distance of 0 feet. When seen in February this vein was being tested by two shafts 150 feet apart. The more northerly, No. 1, or "Kingsmill," shaft had been sunk vertically to 85 feet, while at 75 feet cross-cuts had just been started. The vein where exposed at a depth of 30 feet has a dip of 85 degrees northwest. The hanging wall, which is well defined, is much slickensided and grooved vertically. The quartz has been subjected to much movement, showing frequently slickensides along dark seams, which occur for the greater part in the direction of the vein and show over a width of about two feet. Numerous stringers of quartz, from a few inches to two feet in width, extend from the main vein into the foot wall. The greater enrichment occurs along the north wall, where gold is frequently seen along the dark seams in association with iron and copper pyrites. A little native copper was found near the surface in No. 2 shaft. This shaft, the "Eakins" was being sunk on the inclination of the vein and had reached a depth of 25 feet.

Preston East Dome Mines.

On the Preston claim, H. R. 826, in Deloro township adjoining Tisdale, the rock associated with the gold veins is a quartz-porphyry, which in part has been fractured and filled with narrow quartz veins, some of which will average from 5 inches to 15 inches in width. These narrow veins cut across the general strike of the formation in a north and south direction. In places the porphyry has been sheared and fractured, showing dark seams along which gold sometimes occurs. When seen in November, 1910, the property had not been developed beyond some stripping and

*Can. Mining Journal, Vol. XXXII., No. 4, p. 126.

shallow pits. During the winter a compressor nt and 2 Nissen stamps were taken in to test the perty.

Armstrong-McGibbon.

n the Armstrong-McGibbon claim, the northwest quarter of the south half of lot 1 in the fifth concession of Tisdale, there is a band of impure carbonate rock with an east and west strike, which towards the west is exposed for a width of 50 feet. This rock has been considerably fractured in an irregular manner, and quartz veins occur at many points. These veins, towards the west part of the band, have a dip to the south at about 35 degrees, whereas the schistose carbonate rock dips to the north. Gold has been found in very coarse and spectacular form at several places in the quartz, and the best values are obtained along the line of quartz and schist, especially where slips occur. On the west part of this band of fractured rock a 7 x 9-foot shaft had been sunk 65 feet, encountering narrow veins of quartz dipping to the south, in all totalling about six feet. Six hundred feet to the east a second shaft had been sunk 30 feet. Here the quartz veins have a decided dip to the north.

The property was equipped with a 30 h.p. boiler and a 6 x 8-foot hoist, and drilling was being done by hand.

Scottish Ontario.

On the Scottish Ontario property in northwest Whitney there are several veins exposed on the surface with approximately east and west strike.

An 8½ x 5-foot shaft had been sunk 100 feet and 90 feet cross-cuts had been started north and south. The north cut had been extended 80 feet, while at 50 feet it cut a mass of quartz on which drifting had just begun. The rock in the cross-cut is Keewatin greenstone, a soft decomposed basalt at the breast and a hard quartz diorite at 30 feet from the shaft. This hard rock was also exposed in the shaft at 40 feet. The cross-cut was to be continued northward to cut two well-defined veins which were exposed on the surface for over 400 feet.

A 24 h.p. boiler is used to run the hoist, and drilling is done by hand.

Powell Claims.

The claims of the Powell group are in the northeast part of Deloro township. A band of rusty weathering carbonate with much serpentine occurs on M. E. 22, M. E. 21, and adjoining claims This band has a strike somewhat south of west, varies in width from 35 feet to 75 feet and dips to the north at about 60 degrees. In parts of this band there are veinlets of quartz and dolomite in which visible gold has been found. The veinlets of quartz have a general strike of northeast and southwest. In one part argentite occurs in association with the gold.

Two 50-foot shafts one-half mile apart have been sunk in the hanging wall of the carbonate band at points where the rock is much intersected by quartz veins.

Vipond.

This property is the principal claim of the Porcupine Gold Mines Company.

There are several narrow quartz-ankerite veins having a general northeast and southwest strike. When visited in February last the main development had been confined to No. 3 vein, which had been traced for several hundred feet on the surface. A 4½ x 9-foot 2-compartment shaft had been sunk to the south of the vein a depth of 100 feet, and a cross-cut of 42 feet made to the vein. Drifting had been started in both directions along the vein, which at this depth showed a width of 18 inches to 2 feet, dipping to the southeast at about 83 degrees. The vein consists largely of quartz, but in addition there is considerable carbonate, some in the form of clear calcite.

On No. 3 vein a shaft had been sunk 50 feet, but at 23 feet the vein dipped out of the shaft and no cross-cut to it had been made.

One Nissen stamp was in operation and a small amount of bullion had been produced.

Foley-O'Brien.

This property is situated half a mile west of the south end of Porcupine Lake, where, on a ridge of Huronian rock which outcrops through the drift, the main workings are located to the north of the main road.

No. 1 shaft has been sunk 70 feet. The surface was not exposed, but it was stated that this shaft had been sunk on a quartz outcropping. As seen underground, the quartz appears to occur as a lens, but more development is necessary before the character of the ore body can be determined.

At the 37-foot level the quartz mass is about 26 x 35 feet in horizontal dimensions, while it shows in the shaft for 20 feet deeper, and from a lower cross-cutting appeared to be dipping to the east.

A second shaft had been started to the south of No. 1 shaft on high ground, since the first shaft was located close to a creek and much water was encountered.

A 4-drill compressor plant had been installed and 3 drills were in operation.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

The inundation of Port Hood Colliery.

Later information does not throw much light on the cause of the flooding of Port Hood Colliery, but it is now clear that the inrush could not have been predicted, and that, under the circumstances, and with the pumping equipment available, it was quite impossible to do any more than was done to save the mine. Some very uncalled for and injudicious attacks have been made on the management, and inuendoes have not been low that the mine was lost through improper working.

The water broke in at a point where the vertical cover measured 941 feet, in a portion of the workings where no faults had ever been encountered and no signs of water had ever been noticed. When first the water made its appearance it was the merest trickle, but it was regarded seriously because hitherto the mine had been quite dry in this section. The inflow is calculated to have been about 300 gallons per minute, and the low level pump could only handle 54 gallons per minute at the best. It was speedily drowned. Two attempts were made to put in dams, but before they could be completed the water overflowed them. Had there been time to have finished the dams it is extremely doubtful if they could have

been made effective, because of the enormous pressure of the rising water and the broken nature of the roof. The inundation was so utterly unexpected that no proper dam material was at hand, but even had material been ready, it is more than doubtful if it would have availed anything.

The depth of water at a point vertically overlying the place where the water broke in is only 17 feet, and the sea-bottom is bare at low-tide. It is, in fact, just at the end of the shipping pier.

The whole affair is inexplicable, but so far as can be learned no blame can be laid upon the management, except it be that they failed to anticipate the unexpected.

The Port Hood incident makes it evident that in submarine mining nothing should be taken for granted. All possible information should be collected as to the depth and the nature of the cover, and the position and size of any faults or crevices in the strata. The depth of the sand should be tested by drills, and the soundings should be accurate and so arranged to show, if possible, the presence of any hollows or pits in the sea-floor.

No rules can be laid down for pillar-drawing, or the system of working to be pursued in submarine territory, because the local conditions must rule, and local experience must guide the operations. It is obvious, however, that pillar-drawing should be undertaken with great judgment, and that every possible means should be adopted to prevent any decided break in the sea-floor. Such precautions will be especially necessary in the case of submarine territories where more than one seam is being extracted, and where barrier pillars may be superimposed. It may be possible to use with advantage the system of packing the waste by "flushing" with sand, which system has been largely used in Germany and is being now used in the United States.

A reasonable precaution in all submarine mining would be to have in readiness suitable material for building dams quickly. In some places it may be advisable to put in permanent dams, so arranged as to swing or slide into position when required. Ample pumping capacity should, of course, be provided.

So far as is now known, the submarine areas around Sydney and Glace Bay are of a very different character to those of Inverness County. In the Sydney coalfield the sea-bottom slopes very slowly from the shore, and the submersion of much of the coast is evidently the result of slow erosion extending over an incalculable period. There are practically no faults or dislocations in this field, and both the measures and the coal seams maintain a surprising regularity and sameness. The conditions for submarine mining are very favourable, and given only reasonable precautions there is absolutely no reason to anticipate any such occurrence in the Sydney coalfield as has unfortunately befallen Port Hood Colliery. That reasonable precautions are being taken is more than assured, and it may be confidently stated that the people in charge of the mining operations in the Sydney coalfield are fully alive to all the possibilities of submarine coal-mining.

Dominion Coal Outputs.

The outputs for July total approximately 369,000 tons, or 600 tons more than the largest monthly output yet obtained from the Dominion Coal Company's mines. The largest previous monthly production was 368,400 tons, in July, 1908. The figures for July this year are, however, really better than would appear, because in July, 1908, the month had 26 working days, and in the same month this year there were only 25. The average daily output in July of this year was 14,710 tons, comparing with 14,170 tons in July, 1908. The steadiness of the outputs has been noteworthy.

No. 9 Colliery (Harbour Seam) put out 39,920 tons, beating its own record of 38,655 tons in October, 1906. All the Lingan collieries exceeded their best previous performances, contributing 52,000 tons, or one-seventh of the entire monthly tonnage.

No. 14 Colliery is now almost up to its full production, and when the permanent hoisting engine is installed, the equipment of this mine will be complete. It is practically settled that the hoist will be an electrically operated one, and if this intention is carried out, No. 14 will be a colliery without boilers, and consequently without smoke.

In very many respects the new collieries at Lingan will be in advance of the older collieries on the Glace Bay side, but in no respect will the improvement be more marked than in the housing accommodation, and the general surroundings of the colliery houses. It is not so generally realized as it might be how great an influence on the steadiness and morale of a mining population is brought about by decent housing and pleasing natural surroundings. The new houses being built for the colliery workers have rear kitchens and front verandahs, and care has been taken in clearing the woods to leave as many of the hardwood trees as possible. It is pleasing to note how many of the residents have cultivated kitchen gardens, and to observe flowers and creepers around the house fronts.

The improvement in the Springhill output continues, and from 1,000 to 1,400 tons a day are now being mined. The July output was about 27,000 tons.

ONTARIO.

Cobalt and Gowganda.

While the tonnage shipments from the Cobalt camp for the first six months of this year are almost 3,000 tons less than for the first six months of 1910 the value of the ore sent out is almost two million dollars higher. The figures for the first quarter of the year are official, those for the second quarter are based on the tonnage shipped, the same ratio of silver ounces per ton being allowed as in the first quarter. As concentration has increased during this period and the shipments of low grade ore decreased, the estimate should be exceeded. The official return for the first quarter of the year was:

First Quarter.	
Ore	$3,358,273
Bullion	350,271
	$3,708,544
Second Quarter.	
Ore	$3,883,460
Bullion	380,329
	$4,263,789
First six months of 1911	$7,972,333
First six months of 1910	6,103,372
Increase for 1911	$1,868,961

The La Rose Consolidated is now for the first time since the property was taken over, working the Violet mine, near Cross Lake. The old shaft, sunk five years ago by the original owners, has been pumped out and work may be resumed from it. Under the old owners this property yielded two cars of ore. It is in the diabase formation, which has not been very profitable digging for mine operators.

Having secured some fresh capital, the Rochester Mining Company has let a contract to the Lumsden Mining Company to open up its property from the 200-foot level of the contractor's shaft. At this depth the Lumsden opened up a vein carrying much smaltite and some native silver, and it is proposed to follow this and other veins over the boundary of the property on to the Rochester, which has been idle for some time. It is interesting to geologists to notice that, like the Temiskaming, the Lumsden has found the diabase under the Kewatin, and, like them too, find that the values do not persist

The probability of this development was discussed by ril Knight in a paper he read before the Cobalt branch Canadian Mining Institute some months ago. He then ed that after about 600 feet of diabase had been pene- the Keewatin would be encountered again, and with it five—Mining journal 8 point .... ce of getting more silver values. It remains to be seen of the South Coleman operators will have the courage ir convictions and expend money in sinking and dia- drilling for the Keewatin underneath.

Ca ain A. A. Hassan has returned to the Cobalt field and s that he has a considerable sum of money to continue pment at the Cobalt Station Grounds. Contracts may be her to the Cobalt Lake Mining Company or the City of to continue their drifts into the Station Grounds pro- and so develop it.

It s again reported, with some colour of probability, that & N. O. Commission is going to build an electric line lk Lake and Gowganda. It is likely that the line, if it t at all, will be constructed on the same terms as the ger extension from South Porcupine, namely, that the for the scheme is to be provided by a private company, vill receive back its money in a percentage of the returns. It is said power is to be developed at Engle-

Elk Lake some bags of ore have been discovered, stolen, aid, from the Lucky Godfrey shipment more than a year Some 25 bags have been discovered, and it is said that nstable who has made the find it hot on the trail of more. well posted mining men it has always been doubted if ss through the highgrading operations was quite as high company imagined, though it has always been conceded ome high grade ore had been taken and rock substituted place.

Crown Reserve has completed its contract with the Prus- overnment. The million ounces were contained in seven f high grade ore, the last of which left Cobalt the end month.

standing of the Temiskaming Mining Company on July cording to its own statement, was:

in banks	$247,902.38
from smelters	42,659.00
hand	35,944.85
nts receivable and stock in hand	25,119.86
ned insurance	3,138.05
	$354,764.14
nt and taxes payable	44,812.41
	$309,951.73

Philadelphia Syndicate which purchased the Cobalt Cen- ine, is now attempting to induce old stockholders in the t Central to put up more money to further develop the rty at Diabase Mountain. The committee representing hiladelphia Syndicate consists of Alfred S. Elliott, Wil- J. Haines, and Spencer W. Wright, with head office at Chestnut Street, Philadelphia.

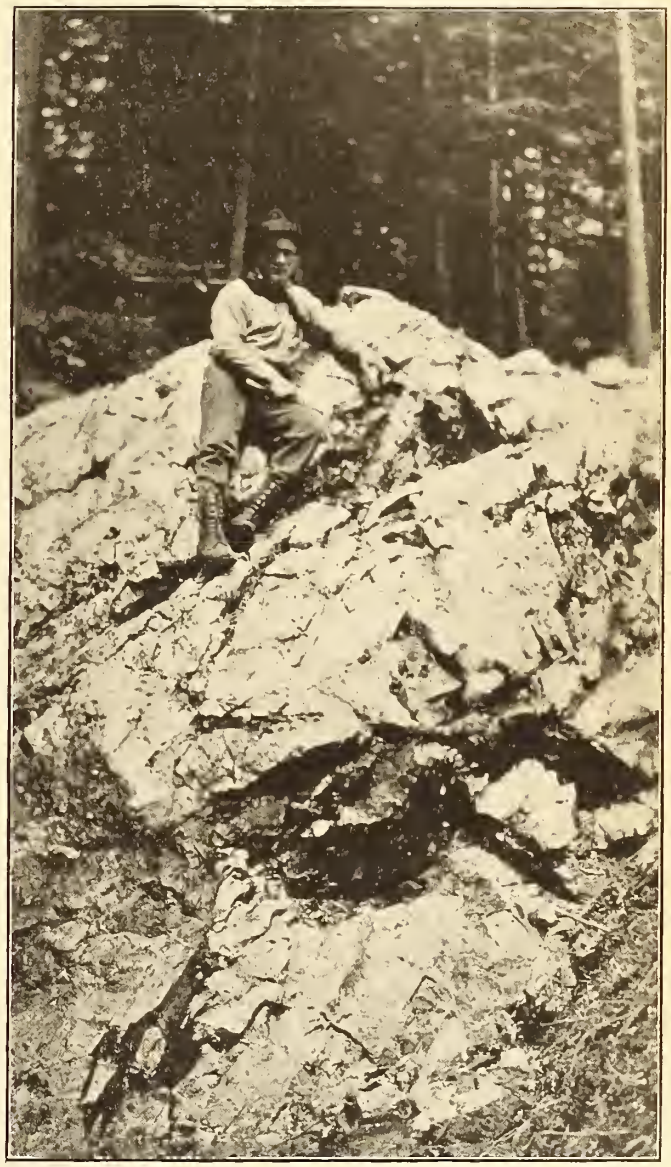
ing the first six months of 1911 the Crown Reserve mined the amount of $795,829, while the mining profits amount- $654,287. The cost of mining was 11.467 cents per , a third of a cent lower than the cost for last year. Dur- he six months $53,644 was paid out in dividends, leaving h surplus of $45,582.

itration is still in progress in relation to the strip of expropriated from the Cobalt Lake Mining Company by '. & N. O. Railway. Two sittings have now been held, he third will be opened shortly in Toronto.

Coniagas paid another 6 per cent. regular and 3 per extra dividend on August 1st, which meant a disburse- of $360,000. The company has to date paid 62 per cent., or $2,480,000. With ore reserves of 16,000,000 ounces almost untouched, the Coniagas holds a very strong position in the Cobalt camp.

Porcupine and Swastika.

The general work of reconstruction after the fire has hardly commenced at the mines affected with the one exception of the Dome. They were not in a sufficiently forward position to have any extensive plant, and since the fire wiped everything out there has been considerable deliberation before ordering fresh plants. Much good work has been accomplished fixing up the mine roads, clearing and preparing for the erection of



Quartz Outcrop on Martin Group.

the plants. The Dome, having plans fully matured, commenced with the utmost speed to replace what it had lost. It employed every man it could find to build a spur out from the main line to the mine, so that the new and very heavy machinery could be unloaded right at the foundations of the plant. It secured a second-hand plant exactly similar to the one burnt, so it will be able to place it on the old foundations. It is very desirous of immediately proceeding with underground work so as to open up other levels.

It is now known exactly where the spur line to the Hollinger will go. By extending the line somewhat it has been possible to avoid a very heavy rock cut, and the line should be running into the Hollinger by the first of October. Now that the T.

& N. O. Commission has definitely picked the spot for the station at the Timmins townsite, the lots should be on the market in a few days. So heavy has been the demand that it has been decided to auction them on the understanding that every lot will be furnished with water and drainage by the vendors.

The Jupiter mine has continued to be the scene of good discoveries. On what may possibly be another vein running parallel to the first at the hundred foot level, another extremely rich lens of ore has been struck about 40 feet from the former. So rich is the ore that after it had been picked over several times it still yielded minute nuggets and fine gold on panning.

There is now a very bad congestion of traffic on all the sidings in Porcupine or on the Porcupine branch. It is estimated that 380 cars are lying between North Bay and Porcupine waiting to go in and the merchants at the gold camp have not been able to unload the freight as fast as they hoped. There was a dearth of teams and the road between the railroad and South Porcupine was long delayed. It is claimed that to-day there are a million and a half feet of lumber required in Porcupine, and only 350,000 feet have so far reached the gold camp. The same conditions prevailed at Cobalt after the fire, and only time can remedy the state of affairs.

The Brydge McAulay claims in Bristol township have been sold to B. E. Cartwright, of Toronto, president of the Temiskaming mine at Cobalt, for half a million dollars. The first payment is small and the installments are spread over two years. The vein is of quartz and ankerite and free gold can be discovered in the quartz all across the vein, and it is fully twenty feet wide on the average. An action for an interest has been started, but it is not expected to form any impediment to the deal.

The British Canadian Power Company has finished its surveys at Waiwaitan Falls on the Matagami River, and 25 men are now employed laying out camps for the 250 men who are to be employed at the work of erecting a dam and putting in machinery for a plant to supply 800 horse power. The water power consists of a series of falls about 18 miles from Porcupine.

Work recommenced on the Hughes property has already brought results. Two new veins running parallel to the first find have been opened up and traced for a distance of 200 feet.

Mr. Walker Ross, who has been put in charge of the Standard Mines, where everything was lost in the fire, will not bring in a fresh plant till he has done a very considerable amount of diamond drilling and prospecting. It is said the Imperial Porcupine will soon start up again after its complete demolition by the flames.

After duly considering the claims of the prospectors for extension of time in which to do assessment work, the Government has decided to grant a general extension of 60 days, with power to Mr. Bruce, the local Recorder, to still further extend the time limit in any cases he thinks particularly hard. It was at first proposed to make a year's extension, but this was opposed as likely to foster the speculative spirit in the camp.

Under Mr. Rickart, the new manager of the Foley-O'Brian, work has been resumed and new camps are being built. The Foley-O'Brian was fortunate enough to save its plant, and the principal loss it sustained was loss of time owing to the impossibility of housing the men. Work has also been resumed on the Vipond and the ten stamp mill which was to have been installed this fall will probably now be brought in as soon as it can be supplied and hauled over the road.

It is now anticipated that the Swastika plant will be set up and in running order by the end of August. The new plant consists of an eight drill compressor, two 125 horse power boilers, and a complete equipment. It will now be possible to continue development on a much larger scale, former operations being very largely curtailed by the small and antiquated plant.

An excellent discovery has been made on the claims of the Pike Lake Mining Company at Swastika. There had previously been discovered a wide vein of quartz and ankerite, and in it a very little fine gold. Recent developments have opened a rich section in this vein. Another good discovery has been made on the Hurd claims on the north side of the track. This property is now known as the Lucky Cross Mines of Swastika.

The Porcupine Canada Gold Mines, Limited, has purchased through Baron von Polenz, the Joslyn, the Canadian North Explorers, and the Kahle claims in Tisdale township. The people interested are mainly Germans and Englishmen.

Captain A. S. T. Stevens, who has resigned from the management of the City of Cobalt mine at Cobalt, was given a handsome present by the men when he left the company. The contract made with the Northern Customs plant to mill ore of Cobalt ore has expired and has not been renewed, the Customs company desiring to turn its attention to Cobalt site ore in preference.

BRITISH COLUMBIA.

At the time of writing (August 1) the outlook for a resumption of work at the coal mines of the Crow's Nest district is not thought to be encouraging, except that information has been received of the intention of the Corbin Coal and Land Company to reopen its mine at once. This company, however, is differently situated to others in the district, in that it has an immense body of coal which can be mined—practically quarried—from the surface, and this will give a large tonnage over a long period. A press despatch from Fernie contains the information that the Crow's Nest Pass Coal Company's employees near there, numbering more than one thousand men, have decided not to support resuming work on the conditions proposed by the Board of Conciliation contained in the majority report made to the Minister of Labour. Meanwhile the exigencies of the situation are being improved by a reduction of railway freight rates on coal from the United States and the announcement that a rebate of the Customs duty will be made on coal shipped from the States to the parts of Western Canada most affected by failure of the ordinary sources of coal supply.

East Kootenay.—The Sullivan mine continues to be one of the chief sources of lead ore supply for the Consolidated M. & S. Company's smeltery at Trail. The output for the seven expired months of this year has totalled between 9,000 and 10,000 tons. The St. Eugene, for many years the largest and most productive lead mine in Canada, has shipped about 8,000 tons of lead-silver concentrate during the same period, being the product of between 20,000 and 25,000 tons of ore mined and put through the concentrating mill. Several other properties in Fort Steele mining division are being worked, but as yet their production is insignificant. Placer mining is being carried on in several parts of the district—on Wild Horse, Perry, and other known gold-bearing creeks.

Slocan.—The Canadian Pacific Railway Company having let a contract for the construction of a spur line, to be about four miles in length, from its Slocan railway at Three Forks to near Bear Lake, chiefly to provide railway transportation for the Rambler-Cariboo and Lucky Jim mines, an aerial tramway is to be erected from the former mine to the site to which its concentrating mill is to be removed. The distance from mine to railway will be approximately two miles. The mill site will probably be near the railway, so as to admit of economic shipment of concentrates from the mill to the smeltery. Financial arrangements have been made for the improvements decided upon. Much ore of good grade has been opened on five levels, namely on the 700, 800, 900, 1050, and 1250 foot levels, and the main adit is being extended on the 1400 foot

el to cut the downward extension of the three oreshoots ened in the higher levels. Several years ago this main adit s driven 4500 feet with the object of draining the old work- s of the mine and doing away with pumping and hoisting. ce then connection has been made with the old shaft at the -foot level and other levels below that have been opened. w there is a comparatively large tonnage of ore available extraction, but since the forest fires of last summer de- oyed the railway for several miles, it has not been prac- able to ship a large quantity of ore. The construction of C. P. R. spur line will do away with this disability. Ship- nts of ore from this mine during an earlier four-year period alled 14,500 tons, having average metal contents as follows: ver, 127 ounces per ton; lead, 37 per cent.; zinc, 14 per t. Average metal contents were rather lower last year, but some shoots of high-grade ore have since been opened, good urns are looked for. Last winter, when snow was on the und and hauling was good, shipments of ore were at the e of about 200 tons per month. Preparations for shipping from the Lucky Jim mine, which in past years has been largest shipper of zinc ore in Canada, are being made, so to be in a position to regularly maintain a fairly large out- t after the railway spur shall be completed to within a short tance of the mine. The Lucky Jim also has large reserves ore, and the mine has been developed to an extent that will mit of its production being an important one.

Nelson.—Lode-gold mining in Sheep Creek camp is on a adually increasing scale. Mill plant and machinery is being talled at the Mother Lode mine; the Nugget is being sely examined by representatives of United States capi- lists who have this property under bond; the Queen is be- g opened to a deeper level; and the Kootenay Belle is also aping well for future production. Several other properties e being developed, some of them with good prospects of be- ming producers. Lead ore has lately been found in the cinity of Sheep Creek camp, and some prospectors are now ving attention to this mineral. The Emerald lead mine, near lmo, in this district, has shipped much lead ore in recent ars, and has heretofore been the only lead mine in the Nel- n mining division. Mining in Erie and Ymir camps is still progress, but without much ore production just now. Near e town of Nelson the chief producer is the Granite-Poorman roperty, on which a 20-stamp mill is kept running.

Boundary.—The smelting works of the Granby and British olumbia Copper Companies have been kept in operation, sup- lies of coke having been obtained from Pennsylvania during ie last three months. There is not much being done in the ay of producing ore in this district other than the operations the two companies just mentioned. The Greenwood-Phoenix ramway Company is persisting in its work of driving a long nnel from Boundary Creek near Greenwood into the moun- in in the direction of Phoenix, but so far no orebody of com- ercial importance has been encountered. Good results are xpected ere long, though.

Portland Canal.—The most important mining operations in rogress in this district are those of the Granby Company in ie vicinity of Goose Bay, Observatory Inlet, the latter being n arm of Portland canal. The company has about 80 miners t work developing the Hidden Creek copper mine, and a num- er of mechanics and other employees making surface im- rovements. The mine is stated to be developing satisfac- orily, giving promise of proving a large copper mine. It is nlikely, though, that much ore will be shipped to smelteries his year, the company's present policy being to further develop large tonnage and to otherwise prepare for putting in its wn smelting works at such a place as shall be found most dvantageous.

In Portland Canal camp proper the Portland Canal Mining Company and the Red Cliff Company are operating energetically. The former company has added more machinery and plant to the equipment of its concentrating mill, which was running to full capacity by the end of July. The mine is in excellent condition for regularly maintaining a sufficient supply of ore to keep the mill fully supplied, and development work is being kept well ahead. The Red Cliff Company has been awaiting the completion of the 12 miles of railway that will provide transportation facilities for shipment of ore to Stewart, where it will be loaded on steamers for conveyance thence to the Tyee Copper Company's smeltery at Ladysmith, Vancouver Island. It is stated to be the intention of the management to ship 100 tons of ore per day. Ore is being opened on three levels in the mine. Water power has been substituted for steam to drive the compressor. A gravity tramway down to the shipping bunkers is about completed, and other preparations for sending ore out are also reported to be well forward.

Skeena.—This district is receiving much attention this year, particularly the part of it with Hazelton as its centre. The development of a number of promising silver-lead properties is being proceeded with, there now being a prospect of trans- information relative to the known mineral deposits of this portation difficulties being much lessened by the progress made with construction of the Grand Trunk Pacific Railway. Much district is contained in the reports of Mr. W. W. Leach, printed in the "Summary Report" of the Geological Survey of Canada for 1909 and 1910, respectively. Mr. Jas. McEvoy is opening coal measures in the northern part of Skeena district for a syndicate in which Toronto capitalists are largely interested. It is expected that this property will be visited late in August by Mr. G. G. S. Lindsey, and Messrs. Louis Reyersbach and Hugh F. Marriott, of the Central Mining and Investment Corporation, London, these gentlemen being scheduled to make a trip to western mining districts shortly.

Other Coast Districts.—Metalliferous mining on Queen Charlotte Islands seems to be quite unimportant at present. Several years ago many glowing statements were published concerning the big ore deposits reported to have been opened on Moresby Island of this group, but little or nothing is heard of them these days. Prospecting for coal is being carried on in parts of Graham Island, but the gross exaggerations of company promoters, as advertised in some of the provincial newspapers have made many people suspicious of the bona fides of the companies spending so much money in flamboyant advertising. One of the worst offenders in this direction is the "trustee" of the British Pacific Coal Company, which is alleged, among other things, to control "practically the only body of anthracite coal land in Western Canada."

Much activity prevails on one or two of the creeks in Atlin camp, where returns from placer mining were larger in 1910 than in either of the two immediately preceding years. Information concerning gold-quartz mining in Atlin district is given in the report of Mr. D. D. Cairnes, printed in the "Summary Report" for 1910 of the Geological Survey of Canada, including the fullest particulars yet published relative to the pockets of rich gold-tellurium ore found at the Engineer mine, Taku arm.

Vancouver and Texada Islands.—Coal mining on Vancouver Island is on a larger scale this year than in any previous year in the history of this industry, so that last year's record output of more than 1,600,000 long tons of coal is likely to be exceeded this year. There is no metal mining of consequence being done, save that it is reported a large deposit of iron ore, in the vicinity of upper Quinsam and Buttle Lakes is being opened, with promise of results of commercial importance. The mining of gold-copper ore in the vicinity of Van Anda, Texada Island, is being continued, though recent production has been largely restricted to the Marble Bay mine.

GENERAL MINING NEWS.

NOVA SCOTIA.

Glace Bay.—A new record for coal production was hung up at the collieries of the Dominion Coal Company last month. The output reached the splendid figures of approximately 369,000 tons. This is the largest output in any one month at these collieries. The best previous month was July, 1908, when 368,324 tons were produced. That month, however, contained 26 working days, while there were only 25 in the month just closed, which, therefore, in addition furnished a record for the best daily average production all around.

Other features of the output figures for the month are that the men at No. 9 made a new record for that time, getting out 39,920 tons—the best previous month's work at No. 9 resulting in an output of 38,600 tons in October, 1906—and the rapid growth in the output figures for the new collieries in the Waterford district. As will be seen by the figures given below, these new collieries produced about one-seventh of the company's total.

The approximate outputs by the collieries in detail were as follows:

No. 1	50,940
No. 2	68,320
No. 3	16,240
No. 4	36,590
No. 5	29,570
No. 6	22,750
No. 7	17,770
No. 8	17,970
No. 9	39,920
No. 10	15,680
No. 12	25,290
No. 14	21,820
No. 15	3,820
No. 16	1,180
No. 20 (Birch Grove)	1,130
Total	368,990

ONTARIO.

Ottawa, July 31.—Hon. Mackenzie King to-night made the following announcement:

"With a view to relieving the situation as it has developed in the Canadian West in consequence of the prolonged cessation of operations at the coal mines in southern British Columbia and Alberta, an order in council was passed by the Government to-day providing that on and after August 7th the duties on coal will be removed on the southern frontier, west of Sault Ste. Marie for consumption in British Columbia east of the 122nd meridian of longitude, and in the Provinces of Alberta, Saskatchewan, and Manitoba."

The action taken by the Government is based on representations which have been made by the Premiers of Alberta and Saskatchewan, by boards of trade and the authorities of the mining localities in provinces concerned to the effect that a serious shortage of coal in eastern British Columbia and in the Provinces of Alberta and Saskatchewan and Manitoba is likely to result from the prolonged cessation of work in the various coal mines, and that such shortage will be liable to be the occasion of widespread privation and possible disaster among the inhabitants of the provinces referred to. In these circumstances and having in mind the situation as it developed in the Canadian West at the time of the threatened fuel famine [illegible] years ago, it has seemed right and conducive to the pu[illegible] good that exceptional steps should be taken to assist in br[illegible]ing about an avoidance of dangers which might arise fro[illegible] a fuel famine.

It is stated in the order in council that the proposed re[illegible]sion of duties shall take effect on and after August 7th n[illegible]t. and shall continue so long as in the opinion of the governo[illegible]n council the mines may, through lack of operation, fail to [illegible]cure sufficient coal to meet present requirements and fo[illegible]a period of two weeks after the passing of an order revoking [illegible]e order which authorizes the remission of duties. From thi[illegible] will be apparent that if the authorities between now and [illegible]e close of the present week affect a settlement and work is [illegible]o be resumed on Monday next, no remission of duties will ta[illegible]e place. On the other hand, if work should not be resumed [illegible]n Monday next, then practically all coal brought into the P[illegible] vinces of Manitoba, Alberta, Saskatchewan, and British C[illegible] umbia will come in free of duty for such time as the work n[illegible] not have been resumed at the mines and for a period of t[illegible] weeks thereafter.

Porcupine, Ont.—Railway sidings are practically comple[illegible]l into the Dome mill site, over which new machinery will [illegible] taken as the beginning of another forty stamp mill and cy[illegible]ide plant.

Railway building is being pushed in Tisdale, and within [illegible] days mines will be able to get sidings for the shipment of p[illegible] visions and building material. The Government waggon ro[illegible] from South Porcupine to Pearl Lake is about completed.

A twelve-drill compressor plant has been ordered for t[illegible] Pearl Lake gold mines.

Cobalt.—The Violet property, adjoining the Colonial, ne[illegible] Cross Lake, owned by the La Rose Consolidated, is again bei[illegible] worked, after a suspension of nearly five years.

BRITISH COLUMBIA.

Fernie.—The executive of District No. 18 of the United Mi[illegible] Workers of America has acted wisely in deciding to subm[illegible] the question of the acceptance of Dr. Gordon's award as chai[illegible] man of the Board of Conciliation, which recently inquired in[illegible] the differences between the miners and mine owners of th[illegible] Crow's Nest Pass and Southern Alberta, to a vote of the me[illegible] By so doing they relieve themselves of any implication of pr[illegible] longing the dispute for personal ends of any kind which migh[illegible] be levelled at them by persons not conversant with the situa[illegible] tion. As a result of the executive's action the decision is le[illegible] with those who are vitally and directly interested. The resu[illegible] of the vote will be awaited with the greatest interest.

YUKON.

Dawson, August 2.—The largest concern ever organized fo[illegible] Yukon, excepting Yukon Gold of Guggenheims, is now the eigh[illegible] millions company reported from London by cable as havin[illegible] been formed by the South African Gold Field Companies' capi[illegible] tal on advance of John Hays Hammond. It is believed here tha[illegible] the concern takes extensive holdings on the Dominion Quart[illegible] and other creeks organized during the last two years by Arthu[illegible] N. Treadgold, in his giant fight against Yukon Gold. It i[illegible] also reported that the company absorbs Northern Light Powe[illegible] & Coal Company, which invested three million dollars som[illegible] years ago installing electric power. Treadgold has already acquired vast holdings of the Canadian Klondike Mining Com[illegible] pany, including the Boyle concession and dredges.

COMPANY NOTES

TARIO PORCUPINE GOLDFIELDS DEVELOPMENT.

Property Unharmed by the Recent Forest Fires.

e statutory meeting of the shareholders of the Ontario Pupine Goldfields Development Company, Limited, was held at e registered office of the company, 20 Copthall Avenue, Lon, E.C., July 24, Mr. Cyril Wanklyn (the chairman of the pany) presiding.

e secretary (Mr. F. C. Heley, F.C.I.S.) having read the e convening the meeting.

e chairman said: Gentlemen, Forest fires, as you know, are requent occurrence in Canada, but they do not generally a much loss of life. Two years ago in Porcupine the loss fe from a forest fire would have been very small indeed—act, it is quite possible that there might have been no loss fe at all. But since the summer of 1909 growing and flour-g townships have sprung up, a railway has been brought o the field, and settlers of every class have crowded in. In e two years the population of the district has probably in-sed more than a hundred fold, and Porcupine, which a short ago was a simple desert, is now the centre of a very ishing and important community. Happily the loss of life no means so great as was at one time feared would be the ; but a sacrifice of life among men who are practically neers in a new region is always sad, and I feel sure that to e who have suffered, or who may be suffering to-day, the pathy of all present here to-day will be cordially extended. In loss of life and in loss of property this company es-d almost as by a miracle. We had news of forest fires in district towards the end of June, but the principal fire h caused all the mischief in this case seems to have start-n 7th July in the southwest. It swept across the east side he Porcupine field, in a line from southwest to northeast, practically wiped out all it met. It descended in its course ur Camp No. 4, on the Dome mines, and on the townships nd Porcupine Lake. Our other camps were in very serious ger at one time, but in the end they, with the Hollinger the Rae mines, escaped unhurt. Above all, not one single nber of the company's staff was hurt. Our principal danger at No. 4 camp, as I said just now, but here everything was ed by the prompt action of our foreman. What occurred is ribed in a letter dated 10th July, from which I will read an extract. The extract is to the following effect: "The swept over our No. 4 camp, and would have resulted in the plete loss of all our camp equipment had it not been for foresight of the foreman in charge, who, realizing the ger, struck all the tents and buried the whole of our outfit trenches. When the fire had passed, it was difficult to see ere the site of the camp had been." The very latest news, r than that letter, is contained in a cablegram dated 18th y, which is as follows: "Railway opened 1st July; not naged fire; official statement, dead under 70, our camps not naged; no loss of life our staff; fire facilitate prospecting y much." Altogether we may congratulate ourselves upon host fortunate escape, and I think that more than a word of nks is due to the staff and management on the spot for the mpt measures which they took at the time to minimize what ght have been a very terrible catastrophe.

With these few words on the recent fire, I pass to the im-diate affairs of the company. The company proceeded to otment on 26th April, and since then the entire purchase sideration, whether in cash or shares, has been paid. More-er, the fifty mining claims in Porcupine, which we were med to explore, have been registered in the company's me. I hope that this distinct statement will put an end to ggestions to the contrary which have been made, and to the ect that there has even been any difficulty about our titles. No difficulty of any sort ever existed, and the claims are now not only our own, but are registered in our own name. In addition to the mining claims, we also took over some machinery, plant and buildings, to the value of £10,000 or thereabouts. The machinery includes boilers and a winding and compressor plant, and is practically new. As regards working capital, the prospectus stated that the issue would provide approximately £89,000. As a matter of fact, after payment of the vendors, we were left with £90,000, and of this sum £80,000 is still available for working capital and for the general purposes of the company. We were formed then to acquire and explore 50 mining claims in Porcupine. The area of these 50 claims is about 2,000 acroes, and they are not in one block, but are dotted about the field. Yet there was nothing whatever haphazard in the selection of these claims; in fact they were pegged out by Messrs. Timmins and their friends in the early days of the field. At that time competition for claims was not so strenuous or severe as it became later on, and it was only natural that these gentlemen, who were not in any way hampered in their selection, should have chosen positions which, as it seemed to them, would repay subsequent investigation. The expression "early days of the field" in the case of Porcupine means about two years ago. Little, in fact, was known of this district till towards the end of 1909; we have, therefore, behind us the advantage of all the knowledge of people who were among those who led the way into this new district. Our 50 claims occupy no fewer than 14 different points on the main portion of the Porcupine field. This fact inereases our chance of finding a successful mine, but it also involves a more extended and perhaps more expensive search than would be the case if our claims were all concentrated at one point. There is a distance of seven miles between our extreme north and our extreme south claims; there is a similar distance between our extreme east and our extreme west claims. We shall in our researches be attacking the field simultaneously at several different points. This advantage, in my opinion, far outweighs anything that might be gained by the concentration of our leases in one spot.

For carrying on the work we have established four mining camps at four principal points. Two of these are important head camps, the other two are small subsidiary camps formed for prospecting purposes only. It was on one of the latter—the No. 4 camp—that the fire descended the other day. Other small prospecting camps will be formed at likely points as time goes on. At these camps we have recently been employing from 100 to 150 men. From them as a centre, exploration of the surrounding plains will be vigorously carried out. To assist towards this end we have offered a stimulus, or what I hope will be a stimulus, to our working miners; we have promised a reward of $250 for the discovery of any quartz vein of sufficient value to be opened up. This, I think, will encourage our men to do their best, and in any event it will be particularly useful on outlying claims where supervision might be rather difficult. In the work that lies before us the first essential is a thorough search for surface indications on all our leases. I do not say that here or there we may not sink trial shafts; I do not say that here or there we may not drive on any vein channel that seems important. We have already, in fact, done both of these things on a small scale; but the first essential is a thorough search for surface indications. On this account the character of the surface covering of all our leases is very important. Now our leases are largely covered with trees and with a growth which is called muskeg. This muskeg is a thiek mass on a sediment of fallen leaves and other forest matter. All this has to be cleared away before the real character of the surface can be ascertained. Moreover, until April

in the present year, another obstacle in our way was snow. In March the trees were actually standing in from 4 feet to 6 feet of snow. You must not on this account suppose that the field is unworkable in the winter months; indeed, judged by parallels of latitude, Porcupine is some 3 degrees nearer the equator than London itself. But certain factors which make for mildness in our insular climate are entirely absent at Porcupine. In England, when snow falls, it seldom lies for any length of time, but Porcupine is part of a large continent, and when snow falls there, there it may stay for many weeks. This matter, of course, only affects the question of surface examination. In all other respects work underground or overground can be carried on without let or hindrance throughout the year. But our surface examination must clearly be prosecuted with thoroughness in the coming months. Some promising places must be opened up which in the subsequent winter months can be developed underground. Wherever outcrop indications are favourable there must be trenching and costeaning, and if there are no outcrop indications costeaning must be done at all likely spots. Later on, small trial shafts may be sunk and the veins themselves explored. But a systematic and thorough surface examination is the first essential. It should be all the more systematic because the field is a virgin field, and it should be all the more thorough because purely surface work is limited to the open months of the year.

To assist us in all this work we are having a geological survey made of all our leases. This survey is being carried out by Dr. Malcolm Maclaren, who has already been engaged upon it for some time. Dr. Maclaren is a leading expert on the question of the geological distribution of gold, and many who are interested in good mining know of Dr. Maclaren's work in other connections and in other countries. All speak of his ability and of the value of his experience in the highest terms. I myself have seen the results of his work elsewhere, and I shall look forward to reading his report on our Porcupine claims with the utmost interest. I feel sure that in this report we shall have a document of the greatest possible value to guide us in the work we have now in hand. The branch line from the railway at Kelso is now working as far as Porcupine. The station is near our No. 4 camp, and the line will be continued four miles further west to the Hollinger mine. We shall then have direct railway communication with our No. 1 camp, and the journey from Montreal, which until recently occupied three or four days, will now be accomplished in about 24 hours. In conclusion, I may mention that both Mr. Moreing and Mr. Loring are now on the spot. Mr. Moreing is the head of the firm that is managing our affairs in Canada, and is well known to you all. Mr. Loring is a partner in that firm, and I think he is also their chief mining engineer, and his advice, I think, is second to none in the profession. His acquaintance with the Porcupine field dates from the autumn of 1909. These two gentlemen left London a fortnight ago, and they will have arrived just after the recent great fire. They are both of them directors of this company, and their visit will be most timely. If anything could be considered as wanting to the management on the spot at such a moment, the presence of Mr. Moreing and Mr. Loring will amply supply that want. We have, gentlemen, entered upon a field of great perhaps of unique—possibilities. Everything that can be done is being done to further the company's interests and to push on with the company's work. It is early days yet to talk of actual and definite specific performance; much work has still to be done—work that will take considerable time. I am therefore only able to speak of mere preliminaries to-day and nothing more. There is, however, one impression which I hope I shall leave behind me, and that is the feeling that we are doing everything in our power to make this undertaking a success. There is no resolution to submit to you, gentlemen, to-day. Our business was simply to place before you the statutory report, but my friend, Mr. Richards, who was absent in Canada on the business of the company for some weeks early in the ar, I think, would like to make a few remarks with referenc to the company and its work. (Applause.)

Mr. David Richards: Gentlemen, I am not anxious to m ke a few remarks, but having only just returned from Ca la after an absence of from four to five months, and being ar ticularly identified with this company from its inceptio is very interesting to me to be present at the first ge a meeting of the company. It may be within the knowledg o many of you that Mr. Moreing and I went to Canad i January last in connection with the negotiations which ev u ally resulted in our acquiring this property. When Mr. Mor a and I completed those negotiations and entered into the n sary contracts, Mr. Moreing abandoned me cruelly — he f me in Canada and came back—(laughter)—as it was r necessary that he should be here in London in connection t the organization of the company. Having acquired a prop t in those rigorous northern latitudes, the first thing to do a to prepare to go on with the work.

Consequently, I remained in Canada, opened our busines Montreal, and immediately ordered the whole of the neces r outfit, machinery, compressor plant, etc., to which Mr. Wan has just referred, and all the necessary stores to supply h wants of from 60 to 90 men on the field. This was most n sary, because it is only during the winter that transport ar be effected in these wilds. As an example of that, I m h mention that during the winter, when the ice is good, we goods to the camp, a distance of 40 or 50 miles, at abou s per cwt. But when the frost breaks the cost of transpo i about 10s. per cwt. for two or three miles, as the whole c n try is one morass or swamp. A good deal of preparation a necessary, therefore, in order that we should start vigo u prospecting as soon as the snow cleared. At the beginnin o April we had 90 people carrying on prospecting work upon h property. You are aware that those 50 claims originally e longed to the Timmins-McMartin group. The property es not consist of one mining proposition, but of practically 5 propositions, distributed over a wide field, and some of t n occupying most promising positions in close contiguity to ell proved mines. The field, as a whole, has not yet been ry widely prospected, apart from the two main belts, or ore c n nels, represented by the Hollinger mine on the west and h Dome system to the east. Mr. Wanklyn referred to our w k ing capital as amounting to about £90,000, and I should lik to mention that this company acquired from the Vendors £10 0 or £12,000 worth of good assets in the shape of plant and st s. The examination of the properties has been taken in hand, u naturally over such a large expanse of country it has ly been so far of a cursory nature. However, a good dea or work has been done at three or four centres, and at the p s ent moment about 150 men are at work, principally upon n Miller and Ferguson groups. The Miller is situated clos to the Hollinger mine, and I consider that the prospects are x ceedingly good. We have at present a considerable amoun or talent on the field—indeed, I very much doubt whether ny field has had the advantage of so many capable and qual d men upon it at the same time. Dr. Maclaren has been on e field for two or three months, and Mr. Moreing has gone ut specially to see things for himself, accompanied by his p t ner, Mr. Loring. You will therefore see that nothing is b ng neglected in the matter of development. I should like to y something with regard to the Hollinger mine, of which ry little is known in mining circles on this side. I saw a go deal of that property while in Canada, and I think that in e course of a year or two the Hollinger will stand as one of e great gold mines of the world. It has an extraordinary p s pect at the present moment. It has opened out a pay shoo or 1,600 or 1,700 feet in length and of great width and much h ness. The figures would surprise a great many people. It as proved its main shoot down to 215 feet, and here it has a w h

feet carrying very high values indeed. The Timmins-Mcin people, who were the original owners of this property, o-day practically the owners of the Hollinger mine, and it be very interesting to the shareholders of this company now that the Timmins-McMartin people own nearly one- of the shares of this company. They are, moreover, quite nt to remain as shareholders and await the developments e property. Mr. Noah and Mr. Henry Timmins, as well as John McMartin, form with us an advisory committee in da, and I think we are very lucky in obtaining the co-operation of such influential and experienced people in this business. The greatest advertisement this field has had has been the fire. The loss of life was a great deal more serious than the loss of property. Most of the mines that suffered in the Dome belt were only in their first stage, so that the buildings were of the most primitive kind, and I do not think that the loss has been so very serious. I think that on the whole there will be more activity consequent upon the fire

The proceeedings then terminated.

STATISTICS AND RETURNS

COBALT ORE SHIPMENTS.

llowing are the shipments from the Cobalt camp for the ending Aug. 4, and those from Jan. 1, 1911, to date:

	Aug 4. Ore in lbs.	Since Jan. 1. Ore in lbs.
Badger	.....	55,200
Bailey	.....	40,000
Barber	.....	6,000
Beaver	122,470	967,678
Buffalo	50,600	1,668,984
Chambers-Ferland	.....	831,000
City of Cobalt	.....	557,980
Cobalt Lake	.....	2,447,736
Cobalt Townsite	.....	578,000
Colonial	.....	88,000

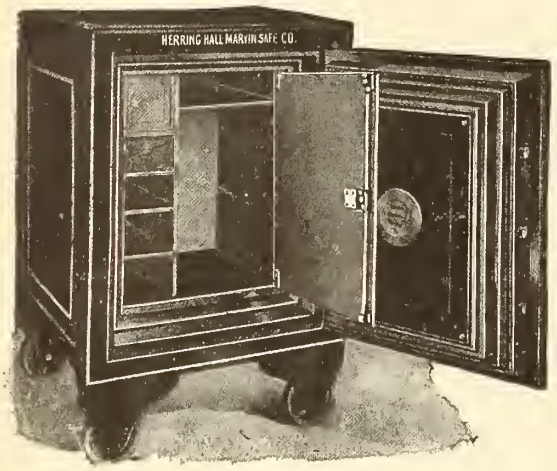
REDUCE THE FIRE WASTE



This is a very important topic these days when there are so many towns and districts being wiped out by fire. A Dominion Safe and Vault Co's Safe will help you to reduce your loss in case of fire. How do you protect your valuable papers, records and books?

It makes no Difference

whether you mill, smelt or ship your ores you must have assays and analyses of unquestionable accuracy reported to you in the shortest possible time. Our equipment is especially designed to meet these requirements.

WE also test ores in a practical way to determine just what metallurgical process is best adapted to it to secure the highest commercial results. Write us for prices for your particular problem.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

DEPARTMENT OF MINES. GEOLOGICAL SURVEY.

PUBLICATIONS

The Geological Survey has published maps and reports dealing with a large part of Canada, with many local areas and special subjects

A catalogue of publications will be sent free to any applicant. A single copy of a map or report that is specially desired will be sent to a Canadian applicant free of cost and to others at a nominal price. The applicant should state definitely the precise area concerning which information is desired, and it is often of assistance in filling an order for a map or report if he states the use for which it is required.

Most of the older reports are out of print, but they may usually be found in public libraries, libraries of the Canadian Mining Institute, etc.

REPORTS RECENTLY ISSUED:

CANADA

1085. Descriptive Sketch of the Geology and Economic Minerals of Canada. Accompanied by a geological and mineral map of Canada, by G. A. Young and R. W. Brock.

NOTE.—Maps published within the last two years may be had, printed on linen for field use. A charge of 10 cents is made for maps on linen.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon. Letters and samples that are of a Departmental nature, addressed to the Director may be mailed O.H.M.S. free of postage.

Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.

BRITISH COLUMBIA

The Mineral Province of Western Canada

Its produced Minerals valued as follows: Placer Gold, $71,213,103; Lode Gold, $60,811,067; Silver, $31,095,602; Lead, $24,645,605; Copper, $60,743,405; Other Metals (Iron, Zinc, etc), $1,083,172; Coal and Coke, $114,012,596: Building Stone, Brick, etc., $10,593,100; making its Mineral Production at the end of 1910 show an

Aggregate Value of $374,197,650.

In 1910 the quantity of Ore mined was 2,216,428 tons, and of coal 3,139,235 long tons. The value of Minerals produced that year was: Placer Gold, $540,000; Lode Gold, $5,533,386; Silver, $1,245,016; Lead, $1,386,350; Copper, $4,871,512; Coal and Coke, $11,108,335; Other Minerals, $1,692,473, making the

Total Value for 1910, $26,377,066.

Lode mining has only been in progress for about eighteen years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those in any other Province in the Dominion, or any Colony in the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with mining Reports and Maps, may be obtained gratis by addressing

A MESSAGE

TO

MINE SUPERINTENDENTS

WHO HAVE

IDEAS OF THEIR OWN

We will build your Skips, Ore-cars, Sinking Buckets, etc., to your own drawings, and exactly as you want them, or we will submit drawings for your approval.

DON'T let anybody force **CHEAP STOCK CARS** on you, when you can get them built as you know they ought to be.

You will find our cars in every Mining Camp in the North.

We are also prepared to furnish Tube Mill Liners. Chilled Wheels and Castings of all descriptions.

THE
SUDBURY CONSTRUCTION & MACHINERY CO.
LIMITED
SUDBURY :: ONTARIO

Province of Quebec

Department of Colonization, Mines, and Fisheries.

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, Etc.

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

MINERS' CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10.00 and it is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $10 an acre for SUPERIOR METALS when more than 20 miles distant from a railway and $20 an acre when less than 20 miles.

For INFERIOR METALS the prices are $2.00 and $4.00 an acre respectively.

The attention of prospectors is specially called to the territory in the North-Western part of the province of Quebec, north of the height of land, where important mineralized belts are known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY 228 ST. DENIS STREET, MONTREAL, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The Bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

THE HONORABLE THE MINISTER OF COLONIZATION, MINES, AND FISHERIES, QUEBEC.

Province of Nova Scotia

Leases for Mines of Gold, Silver Coal, Iron, Copper, Lead, Tin

PRECIOUS STONES

Titles given Direct from the Crown, Royalties, and Rentals Moderate

Copies of the Mining Law and any information can be had on application to

The Hon. Christopher Chisholm

Commissioner Public Works and Mines, - - HALIFAX, NOVA SCOTIA

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

WANTED

AGENCY FOR ORES AND MINERALS.

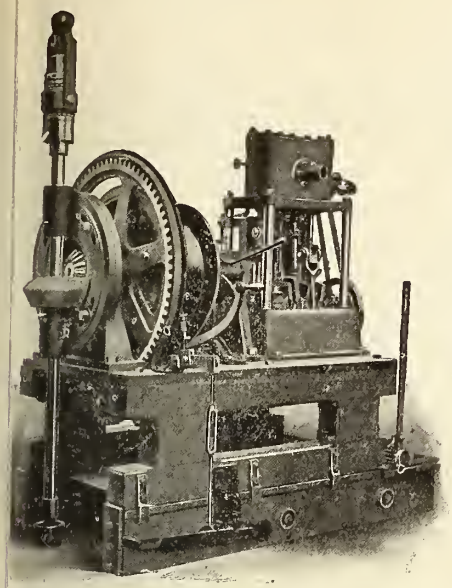
An Ore Merchant who has connections with all the blast-furnaces and electro-metallurgical firms of France desires to communicate directly with firms who produce or sell :—

Chrome Ore; India, Brazil, or Caucasus Manganese Ores; Graphite; Tungsten Ores; Molybdenite Antimony Ores ; Iron Ores ; and Asbestos.

It is desired to purchase Ores outright, or to take over Sales.

AGENCY FOR FRANCE :—

Address—Mr. Ch. CHAUTEN,
123 Rue Lamark, PARIS.



CLASS C.

CORE DRILLS

We manufacture Machines for boring any size hole to any depth. They will do your work cheaper and quicker and give you more core per foot drilled than any other core drill made.

Our machines will bore at any angle up to 45°.

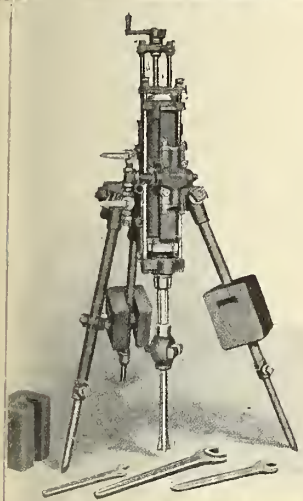
Can be operated by steam, gasolene, electricity or air.

For full information write to

McKIERNAN-TERRY DRILL CO.,

PHIL. H. MOORE, CANADIAN REPRESENTATIVE

KING EDWARD HOTEL, TORONTO.



The "Wizard" Rock Drill will drill a greater number of feet per day, per month or per year, with less power consumed per foot drilled, than any other piston rock drill of like size now manufactured.

ANNOUNCEMENT

THE CANADIAN MINING JOURNAL'S

PORCUPINE SERIES

VOLUME I.

A SERIES OF UNIQUE ILLUSTRATED ARTICLES.

Accompanied by a Complete Geological Map and Claim Maps of the Various Townships

The Publishers of *The Canadian Mining Journal*, in view of the fact that the demand for back numbers containing articles on Porcupine cannot be met, are bringing out a book embodying descriptive, geological, and general data relating to Porcupine. The latest available township maps and a large Geological Map will be included. The object of the publishers is to present in compact form a book that will guide the investor, the engineer, and the general reader.

The book will be on sale within a few days.

The price is $2.00 per volume. For orders of more than ten volumes a reduction of ten per cent will be made. The edition is limited.

Canadian Mining Journal, 17-23 Manning Arcade Annex, Toronto

Secretary of School of Mining
KINGSTON, ONT.

MINING AND SCIENTIFIC PRESS

Controlled by T. A. Rickard | **Established 1860 H. Foster Bain, Editor** | **Published weekly Thomas T. Read, Associate Edito**

In every issue valuable articles are published on mining, metallurgy, and geology, the latest news from special correspondents at the principal mining centers, letters giving the ideas and experience of successful men, and other items of useful knowledge.

THE MINING MAGAZINE

Established September, 1909

T. A. RICKARD, Editor — **Published monthly at London, England**

A monthly magazine is the natural corollary of a technical weekly. It permits of more deliberate and more extended notice of matters concerning which the news element is less important.

The Mining Magazine includes a review of the world's progress in mining, metallurgy, and economic geology, written by men who have personal knowledge of the regions and conditions discussed.

COMBINATION RATE: To new subscribers to both papers in Canada U. S. and Mexico, United Kingdom, Other countries in Postal Union — Combination yearly rate $6.00, 7.00, 8.00

Address either office :—

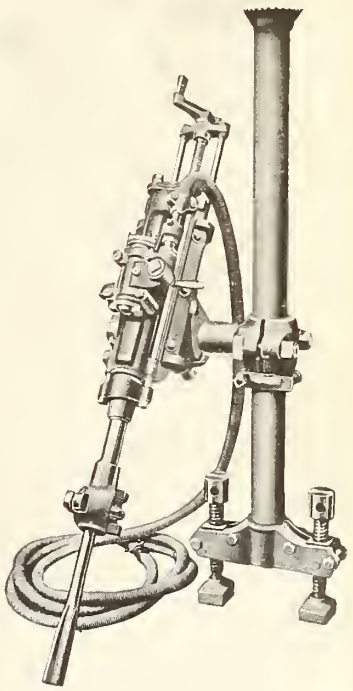
If it's Results you want---

Install Holman Drills.

Mine managers and Superintendents who are interested in Low costs and Increased footage, should investigate and learn what The Holman Drill is doing.



In the vicinity of Montreal, a 3¼ in. Holman Tappet Drill, working in Hard Limestone, is putting in 80 feet of hole in 10 hours.

In one of the principal Cobalt mines, a 3¼ in. Holman Air-Valve Drill, working on a poor air pressure, which never exceeded 70 to 75 pounds, drove a tunnel 5 feet by 8 feet by 104 feet long, in 24 shifts of 9 hours each.

Ask for particulars of Cost Records—they will suprise you.

Send for Catalogue J 38 and Prices

CHOOSE THE RIGHT DRILL

Sullivan 3 inch drill at a Wabana, Nfld, iron mine.

The cost and speed of your rock excavation depend much on the size and type of drill you select.

A machine too large for your work will make your power and labor bills too high. Too small a drill will be expensive for repairs. One valve motion is suited for high air pressure and hard rock, while low pressure or soft ground need another style. But be sure your drill is a "Sullivan." Whatever the size or style, it will drill faster and cost you less for power and repairs, than any equivalent drill.

We are experts in fitting of drills to working conditions.

Our advice is free. Do you want it?

Amatite ROOFING

For Mine Buildings

AMATITE is exactly suited to mining buildings because:

1—It can be laid by unskilled labor.

2—It has a real mineral surface *which requires no painting.*

3—Its cost is lower than that of other ready roofings of less weight.

4—It comes in rolls ready to be unrolled on the roof and nailed down.

5—The necessary nails and cement are supplied free, packed handily in the center of each roll.

The mineral surface of Amatite is somewhat of a novelty; and the fact that it obviates the old painting nuisance, is giving to this roofing the leadership of the ready roofing industry.

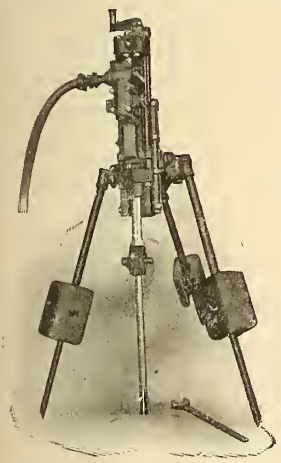
The surface consists of mineral particles embedded under great pressure into a tough plastic matrix of pitch.

A sample of Amatite will be sent free on request.

The PATERSON MFG. Co., Limited
Montreal, Toronto, Winnipeg, Vancouver, St. John, N.B. Halifax, N.S.

"LITTLE GIANT"

ROCK DRILLS



Simplicity is an important characteristic of a rock drill but it must be judicious simplicity. To carry simplicity to a point of imparing efficiency is mistaken economy.

RAND "Little Giant" Rock Drills are as simple as is consistent with the highest attainable efficiency. Every part is simplified to the limit of efficiency, and the number of working parts is reduced to the practical limit, but nothing is sacrificed for the reduction of price.

The "Little Giant" is the "Standard" of Canada, and represents the highest sustained value to purchasers.

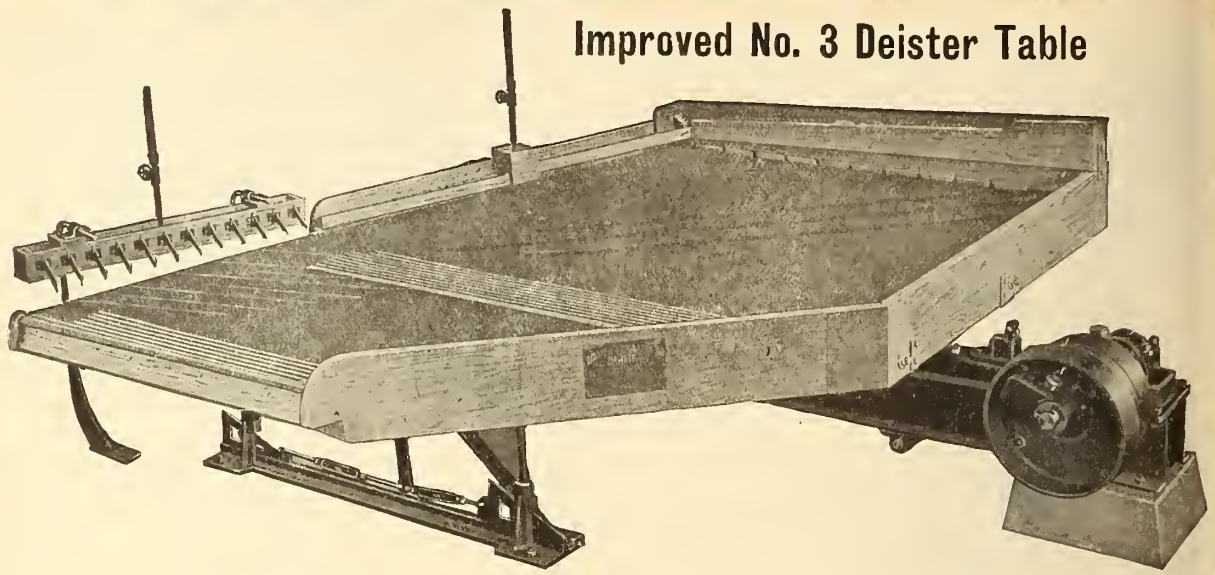
Improved No. 3 Deister Table



THE vanner has been a most efficient type of concentrating device for a decade. Competitive tests in such well known mills as **Goldfield Cons. Mines Co., Goldfield, Nevada; Miami Copper Co., Miami, Arizona; Stratton's Independence, Ltd. Victor, Colorado; Old Dominion Copper Co., Globe, Arizona; Detroit Copper Co., Morenci, Arizona; and Ohio Copper Co., Lark, Utah** have proven the Improved No. 3 Deister table superior in efficiency on feeds of 80 mesh and finer. A pleased customer remarks: "Your No. 3 Table does as good work for us as vanners at a tithe of the cost for repairs."

CLOSE REGULATION

The McEwen is regulated hy the famous BEGTHRUP INERTIA GOVERNOR. With it the engine can be adjusted to govern withln the limit of one revolution without difficulty. The instantaneous variation of speed when the entire load is thrown either on or off is seldom more than one per cent. Ask us to send you our guarantee.

SIMPLICITY

The McEwen was designed for simplicity and thls point has heen carefully preserved .All parts are built to guage, are interchangeable and every part of the machine can be readily gotten at for cleaning and overhauling. Simple positive take-ups and adjustments are provided wherever necessary.

STRENGTH

The ahility to stand up under hard usage is a distinguishing feature of the McEwen. Compactness and rigidlty of design, careful selection of materials, combined with constant and severe inspection of every part, all ensure strength and exceptional rellabillty in the finished engine.

USE

The McEwen has a particular field ln driving electric generators for lighting, power, street railway and mine haulage. Built in simple and compound units up to 700 H.P.

GREENING'S

WIRE ROPE

THE STANDARD OF QUALITY

THE best rope in the world is none too good for use in hoisting men up and down a mine shaft. Both from a humanitarian and a business stand-point, only the strongest and most reliable ropes should be used for this purpose. Greening made ropes are known throughout every mining region in Canada for their reliability. For our Swedish Charcoal ropes, we use only a specially high-class Swedish rod, drawn and thoroughly tested in our own well equipped mill. And we make also a large variety of ropes for a large variety of purposes; our best known lines being Greening's Standard Crucible Cast Steel Wire Rope; Greening's Best Plough Steel Rope; and Greening's "Acme" Steel Rope.

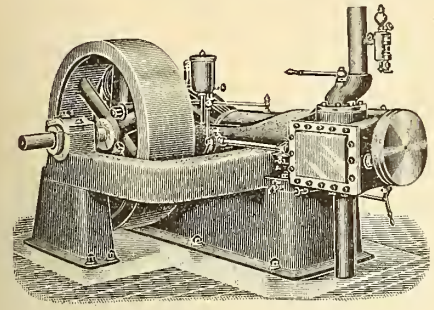
BEARINGS IN LINE



In sizes up to 125 horse power, the outboard bearing of our side crank engines is connected to the frame by a wing, keeping the bearings perfectly in line.

These engines are built on the interchangeable system, and duplicate parts are kept in stock, ready for shipment on receipt of order.

They have our latest improved governor and oiling system and are strictly high class in every respect.

Why the C.P.R. North Toronto Route to Ottawa and Montreal is the Logical One

The train leaves as follows:

Leave North Parkdale - - -	9.15 p.m.	Leave West Toronto - - - -	9.30 p.m.
Arrive North Toronto - - -	9.40 p.m.	Leave North Toronto - - -	10.00 p.m.
Arrive Ottawa, 6.50 a.m.		Arrive Montreal, 7.00 a.m.	
Daily.		Double Electric Berth Lights.	

¶ The residents of Toronto are adjacent to either North Parkdale, West Toronto or North Toronto stations, same being easily accessible and close to residential districts.

¶ The North Toronto route is over an hour faster and overcomes a long hill climb for the train out of Toronto obviating any inconvenience and ensuring early arrival at Montreal and Ottawa.

¶ The roadbed has been improved till it is unexcelled in Canada. Practically half the line is double tracked.

¶ The equipment is "Canadian Pacific Standard," a synonym for the "best" and attentive porters, ensure efficient service.

THE USE AND CARE OF MINE-RESCUE APPARATUS.

The United States Bureau of Mines is attacking vigorously the problem of educating the coal miner in the use of mine-rescue breathing apparatus. In addition to distributing carefully written pamphlets, the Bureau has arranged to hold a National Safety Demonstration late in October of the present year. The Demonstration is to be held in Forbes' Field, Pittsburg, under the joint auspices of the Bureau, the American Red Cross Society, and the Pittsburg Coal Operators' Association. The date selected is October 27th. Elsewhere in these columns the reader will find full details.

This is but one of the steps taken by the Bureau to give the movement right publicity. The most effective step is the distribution of educative literature.

The latest bulletin, Miners' Circular 4, compiled by Mr. James W. Paul, is most informing. After a general statement , in which reference is made to the fact that the Government of British Columbia requires breathing apparatus to be kept at coal mines, Mr. Paul proceeds to describe four types of apparatus — the Draeger, 1907 type; the Draeger No. 2, 1910 type; the Westphalia; and the Fleuss or Proto. He advocates the use of mouth-breathing types, in which the eyes are protected by detached goggles and the nose by clips. The helmet, he believes, is not necessary for safe and effective service in unbreathable gases. The chief disadvantages of the mouth-breathing types are that the wearer is forced to breathe through his mouth and is unable to carry on any conversation, although audible signals are used successfully.

The most important preliminary tests to be applied to any breathing apparatus before it is to be used are as follows:

The quantity of oxygen and air circulated is determined by attaching a measuring bag to the inhalation tube leading to the helmet or mouthpiece, opening the exhalation tube, turning on the oxygen, and then noting the time required to fill the bag. The pressure in the intake tube and vacuum in the return tube; the condition of connections and regenerators; the fit of helmet, and the condition of the complicated reducing valves, should all be determined. Simple directions are contained in Mr. Paul's pamphlet covering all these points.

Especial emphasis is placed upon the proper care of apparatus. Such items as the best lubricant to use are clearly stated. The method of disinfecting is given, and so on. These directions strike us as being thoroughly practical and sane.

In discussing actual rescue work, it is recommended that a rescue party should consist of at least five or or six members. In no circumstances should the men, while working in unbreathable gases, separate. Every member of the party should be within easy reach of the others. Relief parties should be stationed at the nearest point in good air, in readiness to start at a moment's notice. Every large mine should have four crews, each of six men, including a captain and a lieutenant. Weekly practices are imperatively necessary.

The Federal Bureau of Mines has organized and established a course of training for miners. At various stations gas-tight rooms, containing imitation mine entries, and overcasts, have been erected. The air is fouled in various ways, such, for instance, as burning straw, damp hay, animal refuse; or by spraying ammonia, or by burning formaldehyde.

* * * *

The efforts of the United States Bureau of Mines should be followed keenly by Canadian coal-mine operators. It is to be hoped that our own Federal Mines Branch will profit by the example set. The Pittsburg demonstration should be attended by many Canadian representatives.

THE PENNIAC REEF GOLD MINES.

A pained subscriber has sent us a marked copy of The Star Lake Mining News, along with a prayer that we do what we can "to stop this sort of thing."

It may be explained that The Star Lake Mining News is one of those journalistic ephimera that live but for a day. It is published in Winnipeg. Its sole object in life is to induce its readers to buy shares in the Penniac Reef Gold Mines, whose mining claims lie in the district of Star Lake, Manitoba, "only 85 miles east of Winnipeg."

So weary are we of "this sort of thing" that only by the exercise of a very stern sense of editorial duty were we able to read through the sheet. Duty performed brought its own reward. A sentence on the first page caused us to prick up our ears. It ran thus: "The first step of the owners was to interest capital, and to this end one of Canada's most prominent mining engineers was invited to inspect the property, and give a valuation of the mining claims." The "most prominent engineer" came and saw and was conquered. We are informed by The Star Lake Mining News that he offered $100,000 for the claims out of hand. This offer was incontinently refused — largely because the owners hankered to give the public a chance. The "engineer," therefore, made a report and received "his usual fee."

That report, if we may judge by quotations, must have been a jewel. It is asserverated that the ore in sight (this term should have no vulgar definition) amounts to 3,000,000 tons, of an estimated value running up to $34,200,000. The engineering feats that have put this ore "in sight" consist in one 500-foot shaft, two cross-trenches, each 200 feet in extent, and four 20-foot pits. Thirty-five (God save us!) assays have been made. The average, and one can imagine that average, gold content is $11.33 per ton!

Why pursue the subject further? We marvelled at the expedition with which that ore, three million odd tons, was visualized—"in sight" is to prosaic a phrase. What wizard had waved his wand? What conjuror has cozened cold Mother Earth?

The first line on page 2 illumed us. There we discerned and recognized with great joy the name of George R. Thurber, a name honoured (for a time, at least) in other parts of Ontario! Now did we know the inwardness of things!

That our readers may join with us in admiring Mr. Thurber, in hailing him as Canada's greatest professional achievement, we need only quote from an editorial that was printed, published, and distributed by the CANADIAN MINING JOURNAL on October 15, 1910. The caption of that editorial is "Fairy Gold." The text runs thuswise:

"A certain son of Belial is loose in the Lake of the "Woods. Here, at Kenora, he has built him a palace "wherein, by occult means, he renders from the rock "gold not extractable by fire-assay nor by any other "device known to man.

"Indeed, if you wish to get some idea of what this "gentleman at Kenora can do to a gold ore, all that is "necessary is to multiply by three or four the results "obtained by an ordinary or garden variety of assay- "sayer. And so convincing is the manner of his "Kenora person, that several mature persons have also "abstained from chipping in with him.

"We are not unfamiliar with the kind of process "that is being exploited at Kenora. There are many "such varieties, based upon the alleged existence of "'queen' gold, 'latent gold,' etc., etc., and etc. But "the real object of search in all these processes is an "other allotropic form of the metal named 'fool's gold.'"

Our opinion of Mr. Thurber is evident. Evident also, is the fact that he is, consciously or unconsciously, the High Priest of the Order of Fakirs. This is an honourary degree attained only by years of hard labour — and usually followed by a longer term of the same.

THE EIGHT HOURS ACT IN OPERATION.

In the annual report of the Inspector of Mines for the Yorkshire and North Midland District, Great Britain, the working effect of the Eight Hours Act is fully discussed. The Act has been in operation for a year. During that time enough has been learned to discredit many prophecies.

When the Act was being debated, before it had be-
e law, its opponents predicted that accidents would
ease immediately after the adoption of the new
slation. This has not been the case. The Act has
no effect upon the accident rate in either direc
. Thus both those who advocated the Act as a
ns of reducing the number of casualities, and those
believed that mischief would result through
ding, have been proven mistaken.

s to the economic effect of the Act, there is no
n for questioning the fact that the output per
has been reduced; or, putting it another way, the
ber of men employed has been increased without
orresponding increase of output. Working costs
higher, except in a few instances where conditions
peculiarly favourable. The most serious loss, how-
, falls upon wage-earners, especially upon those
were formerly accustomed to work overtime.

pecific facts are given by the Inspector to show how
large group of collieries, producing 15,000 tons
day, has been affected.

this group the following changes have been
ed:

.—The number of coal getters was increased 9.5
cent.

.—The working costs were increased 3d. per ton.

.—The number of tons obtained per man decreased
er cent.

.—The stallmen's wages decreased by 6d. per day.

.—The output increased 2 per cent.

o meet the requirements of the Act, many changes
equipment were necessary. At one large colliery
boilers, increasing the steam pressure from 50 to
pounds, were installed; the winding engines were
d with larger cylinders; cages of four decks were
stituted for those of two decks; more pit room was
vided, and the number of underground workers
increased by 11 per cent. By these steps the
put was enlarged 16 per cent., and the working
t per ton was put up 2.5 per cent.

ther similar instances are on record. In general,
Act has made for higher costs, lower wages, less
put per man, and lower wages. On the other hand,
re is a more equitable distribution of wages. Con-
ry to expectation, there has been little or no
eeding up." Despite the shortened hours, there
nothing to show that the men are working at high
ssure. The facts adduced above afford valuable
rmation for Canadian coal miners. Both operators
employees can draw morals from this authentic
ort.

FLIM-FLAM.

A well known mining engineer, who resides in Co-
t, recently took upon his own shoulders the task
correcting certain scurrilous editorials that were
nted in the columns of a third or fourth-grade Eng-
lish weekly. The name of that weekly — and we hope that it is familiar to but an insoluble residue of our readers—is The Winning Post.

Our Cobalt engineer disposed of The Winning Post's arguments in very short order. However, such is the advantage of an editorial chair, The Winning Post gained a Pyrrhic victory over its correspondent by the simple expedient of having the last word. This, however, does not destroy the correspondent's position. The Winning Post asserted that Canadian mining ventures, organized by Canadians and floated in London, had never paid a dividend. To those who know anything about Canadian mining this contention was too absurd to require refutation. In any case, yellow or pink sheets can never be refuted.

As the Cobalt engineer pointed out, it is lamentably true that many of the worst frauds perpetrated in the name of Canadian mining originate in countries other than Canada. On this point we need not dwell —it is obvious. But we shall animadvert for a moment upon a singularly rank instance that is of putative English birth — although Canadian parentage is possible.

"The Field" is ordinarily a reputable paper. It is a dignified London publication, and its wits are quite as nimble as one may be led to expect.

In the advertising columns of The Field, April 22, 1911, there appeared the following:

"Canadian Exploring Expedition to secure known rich gold deposits, etc., under leadership prominent engineer, will RECEIVE Two more GENTLEMEN; small capital required, sharing pro rata; also few more subscriptions £250, sharing pro rata interest; Government endorsement; bank references — Address 'Box 60,' 'Field' Newspaper, Windsor House, Bream's Buildings, E. C."

Instead of comment we are tempted to insert lurid asterisks. For our Canadian readers no remarks are necessary. Only for the sake of our English contributors are we induced to say a few things.

These few things are as follows: Innumerable "exploring expeditions" are organized every year in Canada. One out of a hundred is successful. Canada has a plethora of prospecting talent. Canada, also, has much discovered mineral wealth. Prospecting, to be quite frank, is not usually a paying game. Big corporations avoid it. The man that is fond of the bush and that knows his business, prospects successfully. He is, however, a rare bird. The rarer bird is he who makes money out of his discovery. Usually someone of the vulture species robs the discoverer of his reward.

Just here we are fearful of being misunderstood. Canada needs the prospector. Canadian prospectors are the best and most vigorous of men. But "expeditions" organized by interests that know not Canada,

or by persons who are making money before discovering anything of value, are foredoomed to failure.

All this, however, is incidental to the real point. The reader will notice that the phrase "Government endorsement" is used in the advertisement. Of this we may say, without equivocation, that it is an unmitigated falsehood. No Canadian government gives its endorsement to any mining enterprise, much less to a vague prospecting "expedition." In short, such an advertisement is a fraud, and the advertiser should be punished promptly and severely.

TIN AND TOPAZ IN NEW BRUNSWICK.

Our readers will be interested in Mr. Brock's description of tin and topaz occurrences in New Brunswick. The discovery of topaz crystals an inch in length is noteworthy. The subsequent discovery of tin by Mr. Brock suggests commercial possibilities. The whole association of minerals (quartz, muscovite, mica, feldspar, topaz, fluorite, wolfrfamite, molybdenite, pyrrhotite, chalcopyrite, and cassiterite) is analogous to combinations found in localities where a certain amount of tin is being produced to-day. For example, Beck's description of the Erzebirge tin deposits in Saxony indicates a close resemblance to the New Brunswick occurrence. From the former both tin and tungsten have been mined in considerable quantities.

In Lunenburg County, Nova Scotia, almost precisely the same geologic surroundings are found near the contact of the granite, or greisen, and the pre-Cambrian gold-bearing slates and quartzites.

Mr. Brock's article deserves attention. Tin is a much sought for metal. It is quite within the range of probabilities that parts of the eastern territory will yield tin in commercial quantities.

EDITORIAL NOTES.

The net income of Granby Consolidated for the fiscal year ending June 30th, 1911, was $282,000. The actual output of copper was the smallest on record since the year 1906.

The next general meeting of the Western Branch of the Canadian Mining Institute will be held at New Denver, Slocan Lake. The Slocan district will receive especial attention. Several papers on mining in the Slocan will be read.

On June 30th, the El Oro mine, Mexico, showed reserves of ore totalling 318,720 tons. The average gold content was $9.50; the silver content 6.1 ounces.

In the week ending August 19, Cobalt mines shipped 13 cars of high grade ore and 8 cars of low grade, making a total of 660.24 tons. La Rose was responsible for 4 cars high and 2 cars low; and Drumm[illegible] appeared on the list after a long absence. Thi[illegible] increase is the more gratifying for the reason tha[illegible] proportion of high grade ore is constantly gro[illegible] greater.

An export duty upon crude ores is being discu[illegible] in Australia. The reason adduced is that transp[illegible] tion and labour are so costly that foreign smelters [illegible] an undue advantage over Australian plants.

Personal and General

Mr. O. N. Scott, mining engineer, Toronto, ha[illegible] moved his office from 14 King Street west, to the R[illegible] Bank Building, King street east.

Mr. R. E. Hore, has been examining mining pr[illegible] ties in the Lake of the Woods region.

Mr. F. G. Stevens, Albert St., Kingston, Ont., ha[illegible] turned from a professional visit to the Gaspe p[illegible] sula.

Mr. J. B. Woodworth, Toronto, recently inspe[illegible] several gold properties in Nova Scotia.

Mr. J. B. Tyrrell has returned to Toronto from [illegible] don, England.

Mr. J. E. McAllister, consulting engineer to the [illegible] tish Columbia Copper Company, was in the Boun[illegible] district of British Columbia about the middle of [illegible] gust, looking into conditions at the company's se[illegible] mines and its smelting works.

Mr. W. J. Dick, mining engineer to the Cana[illegible] Conservation Commission, was in British Columbia [illegible] month. Among other mining districts he visited [illegible] the coal mining region in Nicola valley, where se[illegible] coal mines are being operated.

Mr. Jay P. Graves, of Spokane, Washington, U.S.A., vice-president and general manager of the Gr[illegible] Consolidated Mining, Smelting, and Power Comp[illegible] Ltd., went up to the company's newly purchased [illegible] den Creek mine, near Goose Bay, Observatory I[illegible] about the middle of August. He was accompanie[illegible] Mr. F. M. Sylvester, assistant manager.

Mr. J. R. Roaf, who for several years had bee[illegible] charge of the Crow's Nest Pass Coal Company's [illegible] gineering department at its several collieries in [illegible] Crow's Nest Pass district of British Columbia, ha[illegible] tired from that company's service and gone to [illegible] of the new coal districts about Edmonton, Alberta.

Mr. George Alexander, managing director of the [illegible] toine, Jackson, Ruth, and other mining companies [illegible] ing mines in British Columbia, recently arrive[illegible] Kaslo, West Kootenay, from England. The Ruth-[illegible] group of silver-lead mines, near Sandon, Slocan, [illegible] the Silver Cup, in Ferguson camp, Lardeau dist[illegible] are both operating mines owned by Mr. Alexand[illegible] companies.

Mr. Francis H. Shepherd, chief inspector of m[illegible] for British Columbia, of Nanaimo, B. C., has retu[illegible] from Seattle, Washington, where he took the re[illegible] tion mine-rescue course of training at the U[illegible] States Mine-Rescue Training Station, on the ca[illegible] of the University of Washington. The station had [illegible] closed while the officials were away giving instru[illegible] in coal mining districts, but through the courtes[illegible] of the director of the United States Bureau of Mines [illegible] rangements were made for Mr. Shepherd to take [illegible] regulation training course at the Seattle station.

Mr. W. E. H. Carter, Toronto, reported lately upon groups of mining claims in Porcupine.

Mr. R. W. Brigstocke passed through Toronto on his way to Montreal on August 23rd.

Mr. D. Lorne McGibbon has resigned from the Nipissing board of directors. No explanation has yet been vouchsafed. Internal dissension is the probable cause.

Mr. Walter Baelz, a German mining engineer connected with the Imperial Civil Service, is making a tour of inspection through Canada. Mr. Baelz was in Porcupine at the time of the fire, and there lost nearly all his baggage. He is at present in western Ontario.

Mr. H. W. Hardinge has just returned to New York from an extended trip in the west, and expects to go to Europe on professional business next month.

Mr. Duncan McMartin is the Conservative nominee in Glengarry, his place of birth. Mining men are needed in Parliament .

Mr. Reginald Hore, Houghton, Mich., has been examining mines near Kenora, Ont.

CORRESPONDENCE

Editor CANADIAN MINING JOURNAL:

Sir,—In your issue August 1st, there is an editorial entitled "Geology and Mining." I wish to take exception to several points in that article. In the first place the editorial implies strongly that the geologist should not report upon mines, and that he is not qualified to do so. Here you are wrong. The best mining men I know have begun their careers not as operators or managers, but as geologists. The width of view and the habit of close reasoning that characterize the geological training can not be got in any other way.

Again, I believe that the mine manager, or the operating mining engineer is too often poorly fitted to give any opinion at all upon geology. His point of view is narrower and far more specialized than the geologist's.

I hope that you will be able to see that there are two sides to the question.

Yours, etc.,

J. C. C. L.

PALLADIUM FOUND, NOT PLATINUM.

Editor CANADIAN MINING JOURNAL:

Sir,—Recently there was much excitement at Nelson, British Columbia, relative to an alleged discovery of platinum in a mining camp distant a few miles from that city. Undue importance was attached to the reported find and press despatches were sent out, giving wide publicity to the stated occurrence of the metal mentioned. It transpires, however, that the excitement was premature, and the statements published somewhat extravagant.

The first report was, in part, as follows: "An event which is likely to prove of far-reaching importance in the history of mining in the Kootenays, is the discovery of the platinum group of metals which has been made by A. Gordon French, the eminent metallurgical chemist, while investigating for the best means to obtain fuller results from the treatment of the ores from the Granite-Poorman mine. The discovery was made while Mr. French was examining the float gold and slimes caught by means of a new process, invented by him to meet the requirements of the local ores. . . . The platinum group consists of six metals, and of these Mr. French has identified five. . . . as follows: Platinum, iridium, palladium, rhodium, and osmium. Results from a great many trial assays made by Mr. French show highly payable quantities of these metals, especially in platinum and iridium."

Other similarly highly-coloured reports were published, until warning was given that the mining industry of the district must eventually suffer from a reaction should such an unwarranted course be persisted in, and those responsible for the exaggeration were checked and desisted from their folly.

With the object of preventing "wild-catting," E. R. Widdowson, an assayer of years of local experience, and holding the provincial certificate of efficiency requisite for those practising assaying in British Columbia, informed the Nelson Daily News that "palladium is the predominating metal of the platinum group discovered here by Mr. French. It is obtained from a serpentine dike which is probably an alteration of a peridotite dike. The dike material varies in colour from a dark green to a dark yellow, and is so soft that it can be mined with a pick. The metal is a hard silvery white substance, but is not visible in any of the ore I have assayed. In all, I have made some 50 or 60 determinations for palladium, and the other rare metals, for my various clients, and I am well able to confirm the presence of the metals discovered by Mr. French. However the find may turn out commercially, I think the thanks of the mining community are due to Mr. French for the careful research work he has carried out and is continuing at the present time."

Later in the interview, from which the foregoing is quoted, Mr. Widdowson said: "I can safely say that the metals are present and that I believe they are in sufficient quantities to be of commercial value when a satisfactory method of treatment shall have been decided upon. The various interests are at present going fully into this branch of the question, and no doubt before long a process will be discovered which will extract the metals on a commercial scale."

Since the interview with Mr. Widdowson was published I have ascertained that the investigations had been going on during several weeks before the newspaper man indulged in his hyperbolics. The results obtained by local chemists were confirmed by others in the United States, so that the occurrence here of palladium has been definitely established. The value of the discovery commercially has yet to be determined.

Victoria, B. C., August 16, 1911.

E. JACOBS.

RECIPROCITY AND THE MINING INDUSTRY

(Written for the CANADIAN MINING JOURNAL by A. B. Willmott.*

Now that an election on the reciprocity issue is near at hand, it seems opportune to consider the effects which the proposed changes will have on the mining industry. In the table below all the changes that affect the mineral industry are given.

Import Duties on Products of the Mine.

Article.	Imports into Canada Present Rate	Imports into Canada Proposed Rate	Imports into United States. Present Rate	Imports into United States. Proposed Rate
Asbestos, crude	20 p.c.	Free	Free	Free
Asbestos, ground	25 p.c.	Free	25 p.c.	Free
Asbestos further manufactured	25 p.c.	22½ p.c.	25 p.c.	22½ p.c.
Cement per 100 pounds	12½c.	11c.	8c.	8c.
Coal, slack, per short ton	14c.	14c.	13.4c.	13.4c.
Coal, bituminous, per short ton	53c.	45c.	40.2c.	40.2c.
Coke	Free	Free	20 p.c.	Free
Feldspar, crude	Free	Free	Free	Free
Feldspar, ground	Free	Free	20 p.c.	Free
Fluorspar, crude, not ground, a ton	Free	Free	$3.00	Free
Grindstones, not mounted, per cwt.	15-25 p.c.	5c.	8¾c.	5c.
Gypsum, crude, not ground, per ton	Free	Free	30c.	Free
Iron ore, per long ton	Free	Free	15c.	10c.
Mica unmanufactured	Free	Free	5c. lb. and 20 p.c.	Free
Mica, ground	20 p.c.	Free	20 p.c.	Free
Mineral Waters, not bottled	Free	Free	8c. gal	Free
Oxide of iron as a colour		22½ p.c.		22½ p.c.
Paving stone and paving brick	22½ p.c.	17½ p.c.	25 p.c.	17½ p.c.
Salt in bulk, per ton	$1.00	Free	$1.40	Free
Salt in packages, per ton	$1.50	Free	$2.20	Free
Salt cake, per ton	Free	Free	$1.00	Free
Soda ash, per lb.	Free	Free	¼c.	Free
Slate, roofing, per 100 square feet	75c.	55c.	20 p.c.	55c.
Stone, building, undressed	15 p.c.	12½ p.c.	10c. c.ft	12½ p.c.
Talc, ground	Free	Free	35 p.c.	Free

A study of this table shows that there are no very startling changes. The most striking are the reductions on cement, coal, and salt when imported into Canada, and the reduction on coke and gypsum when imported into the United States. In considering the changes, the view-point of the writer has been that of the Canadian producer of minerals. Changes in the tariff may benefit the producer by enlarging his market or decreasing his cost of production. Per contra, the changes may be injurious by decreasing the market or increasing his cost of production. Many changes may have little effect either way. As there have been no changes in the import duties on dynamite, machinery, drill steel, and other items entering into cost of production, there has been neither benefit nor injury from the operating standpoint. The only exception is that in the case of coal, producing mines in the Province of Ontario will benefit to the extent of 8c. a ton on the coal consumed, which may amount to some thousands of dollars a year in the aggregate.

Beneficial Changes.

COKE.

Coke is produced in the Provinces of Nova Scotia, Alberta and British Columbia. That of Nova Scotia is consumed in the steel industries of that pro and none is exported to the United States, ther ing no smelter industries in the New England St Alberta and British Columbia sold in Canada in 291,453 tons of coke, which were consumed by lead and copper smelters of British Columbia. In dition there were marketed from these provinces in the United States 77,407 tons. The Crow's Nest district produces the best coke west of Pennsylva and so it has been sought by the copper smelters the Northwestern States, because of the lower fre rates and in spite of the American duty. It is p able that the abolition of the United States im duty of 20 per cent. may extend somewhat the over which this coke can be marketed.

GYPSUM.

By the proposed agreement the American im duty on crude gypsum is reduced from 30c. a to nothing, while the duty of ground gypsum remains same at $1.75 In 1909 the production of Canada as follows:

Crude. . . . . 423,474 tons, worth per ton, $
Ground . . . . . 8,814 tons, worth per ton, $
Calcined. . . . . 40,841 tons, worth per ton, $

Total 473,129 tons, worth $809,632.

Of this amount the exports amount to 315,201 t of crude, almost entirely from the Provinces of N Scotia and New Brunswick. Ground and calcined g sum were not exported, and cannot be, owing to high rate of duty. Canadian exporters will pr ably reap the benefit of this reduction of 30c. a

*Consulting Mining Engineer, Lumsden Building, Toronto.

one would expect will extend their markets.

A.

1909 the United States imported in all 403 tons ica. Of this, 167 tons were sent by Canada, valued 133,000, and on which a duty of 5c. a pound and per cent. was paid. Canadian producers will eforth have a perference in American markets by abolition of this duty and should extend their s as well as receive more for their products.

Tc.

here is in Canada one mine producing talc, and mill grinding it. The production in 1909 was 4,350 , valued at the mine at $10,300. The ground pro- t is consumed largely by the paper trade of Can- though small amounts have been marketed in at Britain and the United States. The reduction of import tariff of the United States from 35 per . to nothing will undoubtedly enable this mill to ease its sale in the United States.

Injurious Changes.

CMENT.

1909 Canada produced cement valued at $5,346,- which constituted 97 per cent. of the Canadian sumption. From the United States was imported ent to the value of $51,222, and from Great Bri- to the value of $104,060. There were 22 plants peration, with a capacity of 50 per cent. above Canadian requirements. These requirements, how- , are rapidly growing and in a couple of years overtake the capacity of the mills. The reduc- on the import duty from 12½c. to 11c. per 100 nds will, however, tend to increase the importa- s and so limit the possible markets for Canadian ducers. It should also be noted that one of the f items in the cost of manufacturing cement is , and that the 14 plants located in Ontario are pay- 53c. a ton duty on all the coal they use. This is cient reason why they should have a higher pro- ion than the American plants, which have the ad- tage of duty-free fuel

CL.

oal is produced in Canada in the Provinces of a Scotia, Saskatchewan, Alberta, and British Col- bia. The Nova Scotian coal is marketed in the itime Provinces and the St. Lawrence Valley as west as Montreal. Ontario and Manitoba procure r steam coal from Pennsylvania. Saskatchewan supplies of lignite for domestic purposes and pro- es its steam coal from Alberta. Alberta and Bri- Columbia have their own supplies of excellent m coal.

wing to the American duty of 45c. a long ton, a Scotia coal is shut out of the New England mar- which it could otherwise reach. This coal is, ever, shipped by the St. Lawrence as far as Mont- , where it begins to meet Pennsylvania coal. The uction of the Canadian import duty from 53c. to . a short ton will undoubtedly make the competi- for the Nova Scotia miners in the St. Lawrence ley much more difficult. Their market will prac- lly be restricted by the terms of the pact, no com- sating advantage in the New England market be- given them, as the American duty remains un- nged.

lberta and British Columbia have in the Crow's st Pass some of the best coal on the continent, the rket for which is at present not large. The com- ies operating there would welcome a very sub- tial reduction in the American duty, as it would enable them to ship large quantities of coal southwards into the United States. They would even welcome absolute free trade in coal between the two countries, a policy to which the Nova Scotia operators are quite opposed. The latter argue, and quite properly, that free trade in coal would cause them the loss of the Quebec market, for which they have spent large sums of money in terminal plants for handling. They would at once be compelled to abandon these plants and construct similar ones in New England and would have to spend, in addition, large sums of money in building up a new trade. All of this might be lost through the sudden cancelling by the United States of free importation.

The proposed arrangement has done nothing to increase the markets for the western operators and has without any compensating advantage lessened the market for the eastern producers. It would seem that a true reciprocity would have brought about a reduction of 8c. a ton on the American duty as well as on the Canadian. The loss of the Canadian trade in the St. Lawrence valley would then have been offset by a gain for the Canadian producers in the Crow's Nest Pass district.

SALT.

Last year Canada imported from the United States 81,900 tons of salt, and exported to them 683 tons. Salt is imported free from Great Britain and free from all countries when used in the fishing trade. 61 per cent. of the Canadian consumption is imported and 39 per cent. produced in the counties of Ontario bordering on Lake Huron. There is here a large area underlain by salt of the finest quality, but it finds a limited market in Ontario and Manitoba alone. The eastern provinces and Quebec are supplied by Britain, and all brought in free of duty on merely nominal freight rates by vessels seeking a return cargo from Britain.

Under the proposed free exchange of salt the Canadian producer is bound to suffer severely. One of the chief items of expense in producing salt is the evaporation of the brines. The Canadian producer pays 53c. a ton duty on his coal which the American across the Detroit River receives free. Further in the vicinity of Bay City waste slabs from the saw mills provide the necessary fuel. There are good reasons why the import taxation on coal should be kept up. One of these is that this country requires large sums of money for running expenses and there is probably no easier or more equable form of taxation than one on coal. The transportation companies and manufacturers are the original payers, and through them it is distributed fairly equally over all classes of the community. But if the salt producers, cement producers, and other mining industries are called on to pay this coal taxation they should be given compensating protection for their own products.

SALT CAKE.

One of the most natural industries for Canada would be the development of the alkali trade. The raw material for this is salt, which exists abundantly in western Ontario and is so located that the materials of production can be cheaply assembled. The consumption in 1909 was as follows:

Soda ash	30,560,464 lbs.,	valued at	$249,882
Salt soda..	11,318,633 lbs.,	valued at	106,440
Sulphate of soda	1 961,561 lbs.,	valued at	7,511
Total value			$363,933

Some years ago a plant was established at Sault Ste. Marie, Ont., well equipped and able to produce and sell these commodities in Canada at the current market prices in the United States. As soon as this plant was in operation the American alkali trust cut the prices until they finally succeeded in destroying the business, and the plant was dismantled. Mr. Fielding was appealed to to put a small duty on the production of this plant, sufficient to give it the Canadian market, which market it was willing to supply without any advance in the usual market prices. This protection was refused, and after the plant was dismantled American prices were advanced to the usual point.

Under the proposed arrangement alkali products are put permanently on the free list and the possibility of building up this industry in Canada is practically annihilated.

Inconsequential Changes.

The other changes proposed do not appear to be of much value to the Canadian producer, either one way or the other. Ground asbestos is reduced from 25 per cent. to nothing, and manufactured asbestos from 25 to 22½ per cent. The United States produces no asbestos and this may allow of a little ground asbestos being exported. The United States takes our crude asbestos free and still maintains the prohibitory tariff of 22½ per cent. against manufactured articles.

FELDSPAR.

The reduction of ground feldspar from 20 per cent. to nothing is not likely to induce the establishment of any mill in Canada for grinding. As the market for ground feldspar lies almost wholly in the United States, and as the treaty may be abrogated at any time, a manufacturer preparing to grind feldspar will almost certainly put his mill on the American side of the line.

FLUORSPAR.

This material is at present not produced in Canada, though there is a considerable market here. One promising prospect is known which may be able to supply the Canadian market. The admission of crude fluorspar from the United States free of duty will prevent the development of Canadian deposits and will therefore work as much harm to Canadian industry as the opening of the American market will bring benefit.

GRINDSTONES.

Nova Scotia and New Brunswick produced last year 4,275 tons of grindstones, valued at $54,664. Of these, stones to the value of $13,451 were exported to the United States, and Canada (mainly Ontario and Quebec), imported from the United States grindstones to the value of $66,922. The maritime provinces may possibly extend their New England trade slightly by reason of the reduction in duty, and will lose a corresponding part of their trade in Quebec.

IRON ORE.

The reduction in duty on iron ore passing from Ontario to the United States of 5c. a ton, is not likely to increase the exportation of that commodity by a single ton. Ontario consumed in 1909 543,000 tons of foreign ore and 220,000 tons of Ontario ore. The exportation amounted to 43,000 tons, or one-thirteenth of what was imported. As there is no probability of Ontario meeting her own requirements for years, the advantage of an export market is slight. Iron production in other provinces of Canada is practically nil.

MINERAL WATERS.

The reduction in the import duty of the United States on unbottled mineral waters from 8c. a gallon may induce a slight export trade. Bottled mineral waters are now admitted into both countries at the rate of 17½ per cent.

ROOFING SLATE.

The Canadian duty on roofing slate has been reduced from 75c. per 100 square feet to 55c., and the American duty from 20 per cent. to 55c. The only Canadian quarry is located in Richmond County, Quebec, from which last year 4,000 tons, valued at $19,000, were produced. The imports in that year amounted to $72,000 from the United States. As the Canadian producer was quite unable to take care of his own market, one fails to see how the change in tariff rates can be of any advantage to him. Besides this, the reduction of the Canadian duty will discourage the development of the slate deposits that have been recently found near Haileybury.

PAVING MATERIAL.

Last year Canada imported from the United States paving blocks of the value of $58,335. As the total exports from Canada to all countries of all kinds of stone, wrought and unwrought, amounted only to $5,000, the amount of paving blocks exported must have been very small. The reduction on the import duty should increase the market for the American producer and with no corresponding increase for the Canadian producer. Imports into Canada of paving bricks amounted in value to $101,000, and there were no exports. The Canadian reduction in duty will probably here also increase the market for American material and discourage further Canadian production.

BUILDING STONE.

In 1909 we imported from the United States building stone to the value of $102,000, and exported to them similar material worth $27,000. The mutual reduction in duties will probably result in advantage to the American producer and discourage Canadian production.

Sins of Omission.

An impartial consideration of the proposed arrangement would seem to indicate that the Canadian mineral industry will receive no great advantage. On the other hand it may suffer considerable loss. The changes are not large, and while some are benefitted, and some injured, the industry as a whole is left about as it was.

One cannot help regretting, however, that the opportunity was not taken to bring about changes which would have been of the greatest value to the industry. For instance, the zinc producers of British Columbia, who have large and valuable deposits of zinc, are suffering severely because of being shut out of the American markets. The American import rate is a variable one. but on the material which would have to be shipped is at the rate of 1c. a pound, or about 20 per cent. on the value of the refined material. This is a prohibitive rate. As Canada accepts American metallic zinc free of duty it would have been a fair thing to have asked them to have accepted our zinc ore free. This would have been a true reciprocity.

Again, cobalt oxide is subject to a heavy duty going into the United States, while our cobalt ores are accepted free of duty. This militates against the Canadian smelters engaged in treating cobalt ore and tends to make it more advantageous to ship ore to the United States for treating. The Government could have fairly insisted that a true reciprocity would have admitted not only cobalt ore but the refined product

into the United States, particularly as we receive the refined metals free of duty.

e same conditions of affairs applies to the large l industry centering around Sudbury. The d States has no nickel mines of its own, and re- Canadian nickel ore and nickel matte free of It puts, however, a duty of 6c. a pound (which rohibitive rate) on refined nickel, and so prevents stablishing of a nickel refining industry in On- We take back from their refiners metallic l free of duty. A fair reciprocal deal would be bolition of the American import duty on metallic l, thus giving the opportunity for the establish- of a nickel refining industry in Ontario. This ion has been up for consideration before, but ly with the idea of compelling the refining of l ore in Canada by means of an export duty. This rhaps a questionable policy, but there can be no t about the fairness of allowing a nickel refiner erate in Canada on the same terms as in the d States.

lead ore the Americans place a duty of 1½c. a d, which effectually prevents the operating of British Columbia mines. Here, also, we are tak- back from the United States metallic lead made our own ores at a low rate of duty. It would been of the greatest advantage to our lead pro- rs if lead ore could have been placed on the free

New Brunswick and Nova Scotia two promising nony mines have been operated, but the Can- market is limited. The American duty on llic antimony amounts to 1½c. a pound, while received into Canada free of duty. The removal e Americans of this import taxation would have of great advantage to the producer.

rundum ore is admitted free into the United s, whereas the ground product is taxed $5 a ton. Owing to freight rates, it is necessary to concentrate this material at the mine, and so the bulk of the exports from Canada pay a heavy taxation. The reduction of the rate on corundum would have been of very great advantage to the producer.

Crude graphite is admitted into the United States free of duty, but the partly manufactured material is taxed at the rate of 20 per cent. Here also is exemplified the usual attitude of the Americans, who are willing to take our raw material but strive in every way possible to put the industries dependent on these raw materials in their own country.

Crude barite is subject to an American duty of $1.50 a ton, whereas the manufactured article pays $5.25 a ton. The abolition of this duty would lead to a large industry in Canada.

A consideration of the very numerous ways in which the tariff might have been changed to the advantage of the Canadian mineral producers leads one to criticize adversely the changes which have been made and the methods by which they were brought about. No two ministers of the Crown, no matter how clever, could known the details of the mineral industries of Canada, far less of all the industries of the country. Sir Wilfrid Laurier was perfectly right when he declared that no changes would be made in the tariff until the question had been considered by a commission. A serious mistake was made in allowing the matter to be dealt with by two men who were without adequate advice. It seems that in a few cases personal friends of the ministers advised them on a few items. The great majority of the men engaged in the mining industry were entirely unconsulted as to the changes that ought to be made. The agreement and the method in which it has been brought about, reflect no credit on the commissioners, nor do they accomplish for the mining industry what they might have done.

TIN AND TOPAZ IN NEW BRUNSWICK

Written for the CANADIAN MINING JOURNAL by
R. W. Brock.*

paz and tin have been found by the Geological ey near Burnthill brook, southwest Miramichi r.

olybdenite in small amount in quartz veins has been known to occur at this point, being noted he reports of the Geological Survey for 1866-69 e 206), for 1879-80 (part D, page 45), and in XIV. (page 206A).

st summer the locality was visited by Dr. T. L. ker for the Mines Branch of the Department of s, who found that wolframite, as well as molyb- te was a constituent of the veins.

st winter Mr. Lodge, of Moncton, and Mr. Frieze, oaktown, who took up a mineral location at this t, sent in specimens from their claim, which on ination by Mr. R. A. A. Johnston, mineralogist he Survey, were found to contain topaz as a gan- mineral with the quartz. The crystals were wea- ed. Some were fairly large, exceeding an inch in length and three-quarters of an inch in diameter. Except as a microscopic constituent of a British Columbia granodiorite, this was the first known occurrence of topaz in Canada.

As there seemed a possibility that tin might also be found with such an association of minerals and that fresh crystals of topaz might be clear and of gem quality, I recently availed myself of an opportunity to spend a day or two at the occurrence. It is reached from Boiestown, on the Fredericton branch of the Intercolonial Railway, by driving about nine miles to Campbell Settlement, and a day's poling up the southwest Miramichi in a canoe.

The rocks are argillites, considered by Bailey and Ells to be of Cambro-Silurian age, that have been invaded by a granite batholite. Along the contact of the granite the argillites are metamorphosed to spotted schists and hornfels.

Granite porphyry and aplitic dykes form the country rock. A few basic lamphrophyres were also seen, but at least some of the latter are old-

---

*Director Geological Survey.

er than the granite, as the quartz veins run uninterruptedly through the basic dykes.

Within the highly metamorphosed zone of the sedimentaries which forms a border, roughly half a mile or so wide, along the granite contact, the mineral bearing quartz veins are developed.

About Burnthill brook the veins appear to be best developed and most highly mineralized on the sidehill facing and opposite the mouth of the brook. Near the granite contact, which crosses the brook about a quarter of a mile from its mouth, veins do not seem so numerous nor so well mineralized.

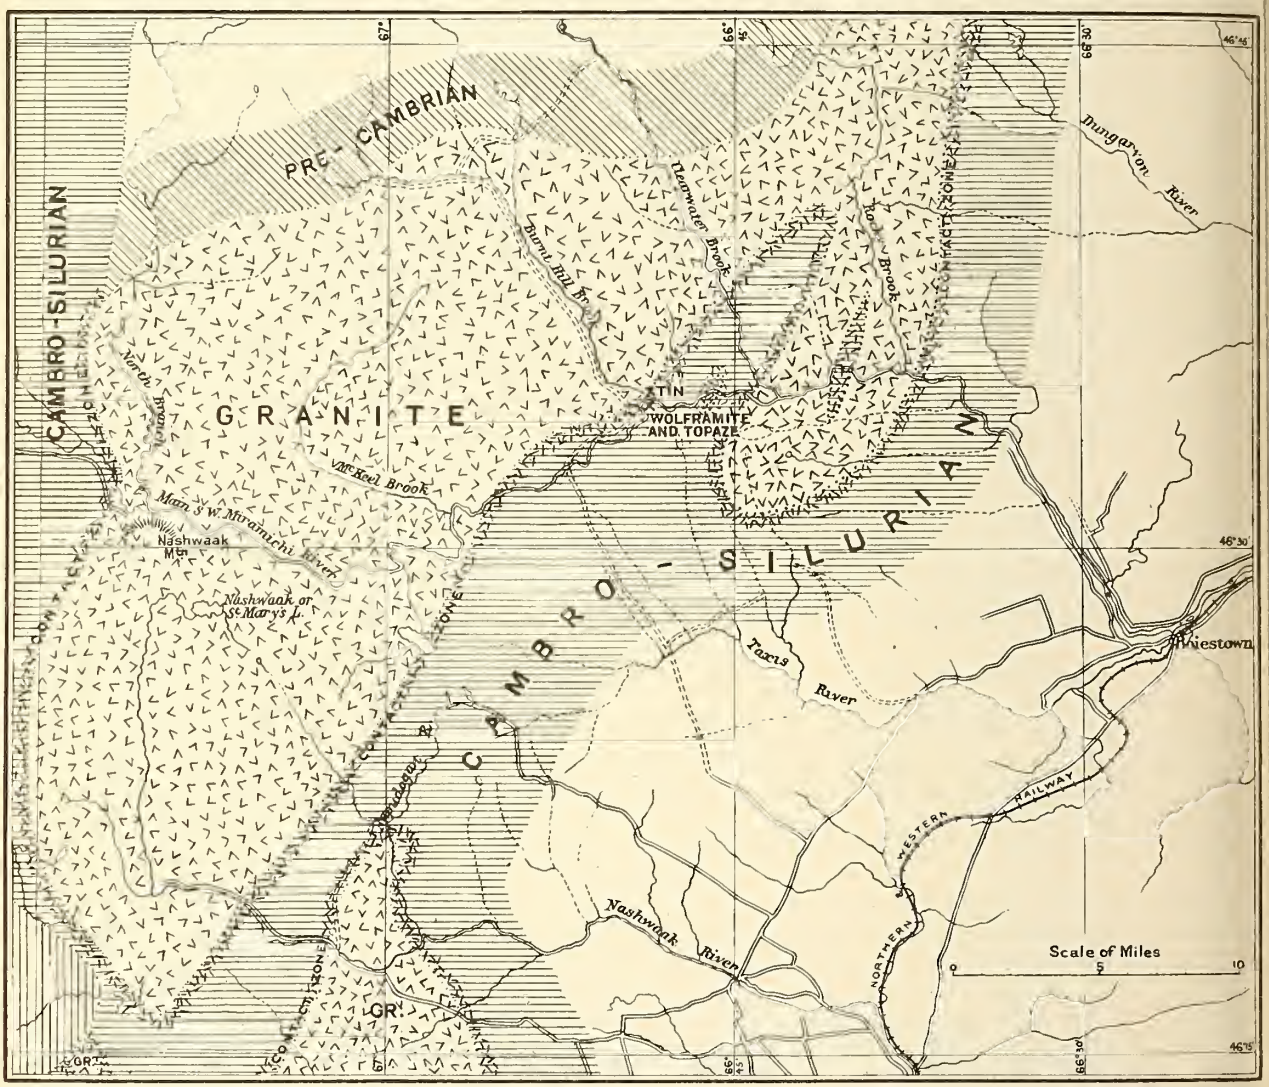
The strike of the country rock varies somewhat but is about N. 67 deg. E.* dip 55 deg. N. Both the sedimentaries and the granite are heavily jointed, the joint planes having a direction of from N. 20 deg. to N. 40 deg. W.

Quartz is developed parallel to the strike of the schistosity of the sedimentaries and parallel to the joint planes. Parallel to the strike, the quartz is irregular, forming lenses and sending irregular stringers into the country rock. Between such stringers the country rock is often silicified. Parallel to the joint planes the quartz occurs in well defined, regular veins which can be traced in some cases for several hundred feet, but some can be seen to pinch out.

*Directions are magnetic.

Some inclusions of country rock occur in the and the wall rock is occasionally silicified, so there has been replacement as well as vein fil The majority of the veins are under a foot in but at the point where the specimens were obta last winter (they were mostly float), I had a uncovered for about 50 feet that averaged at two feet.

On the east side of Burnthill brook, at its m a mineral-bearing quartz vein is bordered by gre a rock consisting of silvery mica and quartz. mica of the greisen, which is muscovite, is often s gated in bands. A little farther north is another in which greisen predominates. North of this,



the granite contact, I found a four foot dyke greisen, parallel to the joint planes and the qu veins. In it were a few quartz stringers and dr of quartz. It was in this greisen that I found stone (cassiterite). There is, therefore, evidentl gradation from the greisen to the quartz veins, the veins are clearly contact phenomena of the truded granite. The following minerals were served in these veins: quartz, muscovite, brown m feldspar, topaz, fluorite, wolframite, molybde pyrrhotite, chalcopyrite, and cassiterite.

The quartz, which is milky and vitreous, is the c gangue mineral. It occurs massive and crystall in vugs and druses. Muscovite is most plentifu

greisen but is also found in the typical quartz . The brown mica was seen in one of the quartz n.

ldspar was found in one of the banded quartz-en veins.

e topaz occurs in a great many, if not in most, of the quartz veins and in considerable quantity. It is mo frequently found as crystals lining vugs and dr es, but it also occurs massive. The crystals are mi oscopic to thumb-large in size. Little unweather-ed aterial could be obtained, and the topaz seen was mo ly cloudy, or stained with iron oxide. Some crys-tal were almost milk white, but some small clear ye w crystals of gem quality were found. In one sm l vein a druse with a surface area of about eight sq re feet was completely coated with topaz crystals. Th dark blue fluorite also occurs in druses but spar-ing.

he brownish black wolframite occurs in consider-ab amount, usually more or less segregated into bu hes which are commonly near the centre or along th edges of a vein. Although bunchy, it is suffi-ci tly plentiful to warrant some prospecting. The mo bdenite is less abundant. Its occurrence is simi-la to that of the wolframite.

he pyrrhotite and chalcopyrite are only sparingly pr ent. The iron sulphide is later than the wo ramite. The brown cassiterite was found in the gr sen in small amount only, but it may occur also in he quartz veins.

he granite in the neighbourhood of Burnthill bro k is for the most part drift-covered, but some is ex osed in the brook itself. Some small quartz veins an pegmatite dykes were observed in it. The quartz ve s were similar to those in the sedimentaries, but only molybdenite was observed in them. There is no reason, however, why tin-bearing greisen, or wolfram-ite-topaz veins should not be found in the granite, especially in fractures near its contact with the sedi-mentaries, where pneumatotytic action would be as apt to occur as in the sedimentaries near the contact.

The district is one that is worth some prospecting. While one cannot yet state that it is present in com-mercial quantity, the wolframite is present in suffi-cient amount to warrant prospecting, and there is a chance that prospecting might reveal larger and rich-er veins. There is also a possibility of finding more tin. Greisen is notably a tin-bearing rock, and the association of minerals is favourable. Some topaz of gem quality would no doubt be found. The stone in the rough is not worth much, but it has some value.

While there are no roads, if a workable deposit were found, transportation would not be difficult. In winter supplies might be brought on the ice or a road would not be difficult of construction; in summer they might be floated on scows down the river from the National Transcontinental Railway and the products floated on down to Boiestown. The chief difficulty in prospecting is the paucity of rock exposures, the wooded nature of the country and the depth of wash and drift over much of it.

To prospect, the contact of the granite should be sought and followed, and prospecting carried on both in the granite and in the metamorphosed zone of the argillites. In the latter the strike of the rocks should be followed as the promising mineral-bearing veins are parallel to the joint planes at right angles to the strike. Where float is found in quantity the source is usually close at hand.

PROSPECTING THREE CENTURIES AGO

o Mr. W. F. Ferrier, of Toronto, the writer is in-d ted for the opportunity of glancing over, gloating o r is the apter phrase, a beautifully preserved little v me printed in the year of our Lord, 1639.

he title page, a delightful example of Carolian type-se ing, is so explicitly descriptive that I reproduce it h e. Cold, modern print robs this title of half its c rm; yet the naivete cannot be missed.

ere is the page:

A DISCOVERY OF SUB-
terraneall Treasure, viz.

C all manner of Mines and Mineralls, from the Gold to the Coale; with plaine Directions and Rules for the finding of them in all Kingdomes and Countries.

And also the Art of Melting, Refining, and Assaying f them is plainly declared so that every ordinary man, that is indifferently capacious, may with small charge presently try the value of such Oares as shall be found either by rule or by accident.

hereunto is added a reall Experiment whereby every gnorant man may presently try whether any piece of Gold that shall come to his hands be true or counterfeit, without defacing or altering the forme thereof, and more certainly than any Goldsmith or Refiner could formerly discerne.

Also a perfect way to try what colour any Berry, Leafe, Flower, Stalke, Root, Fruit, Seed, Barke, or Wood will give: with a perfect way to make Colours that they shall not stayne nor fade like ordinary Colours.

Very necessary for every one to know, whether he be Travailer by Land or Sea, or in what Country, Dominion, or plantation soever hee shall Inhabite

Imprinted at London by I. Okes, for Iasper Emery, and are to be sold at his shop at the signe of the Eagle and Child in Paul's Church-yard next Watlin-Street.

M D C XXX IX

What sublime assurance exudes from every line of this fascinating page! With what eager credulity the good subjects of King Charles must have proceeded to read, mark, and inwardly digest every hint of the way to wealth! Note the seductiveness of the wording—"so that every ordinary man, that is indifferently capacious, may with small charge presently try the value of such Oares." Was ever better phrase coined—"indifferently capacious"! The quaint priggery of it!

The ingenious author, one Gabriel Plattes, dedicates the child of his brain "TO HIS WORTHY FRIEND-

MASTER William Englebert Esquire, Health and Happinesse Temporal and Eternall, is heartily wished." In the course of the dedication we learn that the author desired to share with others his knowledge of the secrets of nature. "Also," he writes, "when I heard the manifold complainings of indigent people, of the hardnesse of the World, and of the difficultie of obtaining their livings: I have knowne many people of indifferent vertuous dispositions, for very want of meanes, to take in hand some actions which were not laudable." What a soul-searching confession!

The dedication concludes with a petition to William Englebert, Esquire, to cause the light of his countenance to shine upon the author, "your bounden Servant, Gabriel Plattes."

There follows a foreword addressed to the reader, a foreword as ingenuous, and as full of self-appreciation as one could wish. Gabriel Plattes explains his reasons for perpetrating the book. "Whereas" quoth he, "divers reasons have joyned together to move mee to take in hand this Taske: I will declare some few of those that may give the best satisfaction to the Reader, in this manner following. First, when I considered the great number of Treasure and riches which lyeth hidden in the belly of the Earth, and doth no good at all: and also the great benefit which might accrew to divers Kingdomes and Countries, by setting people on worke; . . " and so on. In praise of his own prospecting methods he has this to say: "I dare hazard a Wager of twenty to one, that there will be more good Mines discovered within seven years after the divulging of these Rules and directions, than hath beene in twenty-seven yeares before." How rarely modest is our good friend Gabriel Plattes!

There is a strong tincture of caution, however, in Mr. Plattes. He admonishes his readers not to risk everything in prospecting, and not to deem the "rules and directions . . . unpossible ever to faile: but rather to make this a part of his businesse, when hee shall come to such places as yeeld strong probabilities."

He then proceeds no longer "to stay the Reader with Preambles," and signs himself "Your hearty Well- wisher, G. P."

Like all of the chapters, the first is a strange admixture of common-sense, imagination, and superstition. One can see that the author was more than ordinarily observant. In his own quaint way he was part philosopher and part charlatan. He opens his discourse with what is intended for a study in geology, Chapter 1 being "a plaine Demonstration of the naturall cause of the generation and production of Mountaines and Mettals: whereby the Seekers may obtaine a good competent measure of Knowledge to guide them where to seek for the other External signes" of mineral deposits. By a beautiful process of reasoning it is shown that "there is no probability that any metalls can be generated neare unto the North and South poles of the globe, for those can by no meanes have any convenient Matrix for such a generating, being by all probabilities nothing but two Islands of Ice." To this effect the thesis is further developed: "Now whereas the North and South, by reason of their coldnesse, cannot suffer the said condensed Meteors to descend in forme of Water, but in the forme of Snow, Haile, or some substance of like nature, which there cannot melt in the superficies for want of heate, it is very probable that the new Accretion this way produced, doth presse downe still with its weight the said Islands of Ice towards the C[enter], where the centrall heate melteth it off continuall[y], which meanes the spherical forme of both Earth and Water are perpetually preserved." Thus we are asked to look upon the cumulative pressure of snow and ice at the poles as preserving the sphericity of the globe.

So confident is Mr. Plattes in his belief that [all] the mountains of the middle zones contain valuable metals, that he utters the following challenge: "And if any man be of a contrary opinion, I will not [envy] him; but as for my owne part, I will sell my Interest and hope of Mettalls in those places [this refers to the poles] for a Farthing, although I had a device how the cold there could not prevent my seeking [after] them."

It is now shown that "in Vallies and plaine Champion Countries, there is no hope" of finding mineral deposits. The reason adduced is that "the wombe of such earth is not apt for such a generation." Mountains, and mountains only, are to be prospected. Before touching the origin of mountains, the belief is expressed that they are the result of the action of water, "but whether this was done by Noahs Flood or by the Sea in former Ages, is doubted." The result that no further work was done on these.

Chapter 2 is practical. In it are given "the signes of Mines and Minerals, with the manner how to worke to find the same." The first paragraph directs the prospector how to begin: "When we come to the Rocky and Craggy Mountaynes, the first thing we are to observe, is the barrenesse of them; For the more barren they are, the greater probability there is that they containe rich Mines and Minerals." The [word] "barren" evidently means absence of vegetation.

Next, the searcher is instructed to hunt for springs of water issuing out the said mountains. The water being found, it is to be boiled in a "new clean pipkin," to the consistency of "thinne Oyle, but not so thicke as a Syrrup," When cold it must be placed in an "urinall" and set for three days in the coldest place that can be found. The reader is then enjoined "to observe it exquisitely what residence [residuum] it yieldeth: if nothing settle but a black earth or middle, it is a signe of COALES: if some part thereof shoot into Ice [crystallize], or a substance like Ice or Vitroll, then to observe the colour thereof." If the colour be green, it is an evident sign of copper. If whish. "then it may signify any other Mettall without exception."

J. C.

(To be continued.)

A press despatch sent out from Seattle, Washington early in August was as follows: "One thousand tons of copper from the Guggenheim Alaska mines is being loaded on the steamer Protesilaus for shipment to Hamburg. This is the first consignment of Alaska copper for Europe." In connection with the foregoing it will be recalled that the first through train carrying freight over the Copper River & Northwestern Railway left Kennicott, the interior terminus of the line, for Cordova, Prince William Sound, on April last, loaded with 1,100 tons of copper ore from the Bonanza mine. This ore was shortly afterwards shipped from Cordova Bay by steamer to Tacoma, Puget Sound, Washington, distant about 20 miles from Seattle.

The Auriferous Ferro-Dolomites of California

By William H. Storms.*

There is a remarkable similarity between the gold-aring ferro-dolomites of the now famous Porcupine strict, of Ontario, Canada, and those of the Mother de of California. To such an extent is this true, at, in some instances it is difficult to distinguish in hand specimen between those for Porcupine and ose from the California localities. This makes the ology of these far separated regions of particular terest to geologists, mining engineers, and, in fact, all who are engaged in mining in either region. A mber of interesting and valuable contributions, de-riptive of the Porcupine district, have appeared dur-g the past few months in the CANADIAN MINING URNAL, and I believe a brief description of the fer--dolomite veins of the Mother Lode of California nnot fail to be of equal interest at this time.

The gold-bearing belt of California extends in a rthwest direction from the Mexican border, the en-re length of the state, and beyond it into Oregon, it that portion commonly known as the Mother Lode restricted to five counties in the east central part the state, and within this area it possesses distinc-ve features that entitle it to be considered almost as separate mineral province.

The impression commonly entertained by those un-miliar with this world-famous gold-producing region that the Mother Lode forms a great and continuous ein, or lode, which runs uninterruptedly through the untry for several hundred miles. Such, however, not the case. What is known in California as the lother Lode is not confined to a single vein, nor is it ally continuous throughout its length of over 100 iles, but occurs as a series of fissures of branching pe, which have an approximate parallelism. These ssures are found cutting indiscriminately through he various kinds of rocks which happen to be in its ourse. Beginning at its southern end, it appears as large outcrop of white quartz, near the site of the ld village of Bridgeport, in Mariposa county. Bridge-ort, together with many other of the towns of early ays, is now merely a memory. This quartz outcrop ccurs in clay-slate, and is near a large mass of gran-te, which sweeping down from the Sierra Nevada, uts off the southeasterly extension of the earlier ocks. From this place in a northwesterly direction, hrough Mariposa and Tuolumne counties and extend-ng into Calaveras county, the great dolomitic lode ap-ears at frequent intervals, usually as a wide mass of lolomitic rock, which is undoubtedly of intrusive or-gin. In some localities the vein is but a few feet in vidth, but within a short distance swells to a hundred feet or more in width, with occasional branches into the country, one notable instance being found about a mile north of the Rawhide mine, in Tuolumne county. Often the composition of this dolomite is varied by the occurrence in it of a greater or less amount of iron carbonate, forming, then, the rock ankerite (fer-ro-dolomite). This rock appears in huge outcrops, often more than 100 feet, and from that up to 300 feet in width, being always accompanied by quartz in the form of veins, lenses, or masses of irregular shape. Generally the larger of these masses take the form of an elongated lens, which lies practically parallel to the strike of the Lode, these lenses being scattered throughout its width. The more prominent lenses are usually connected by smaller veins of quartz which cross the intervening mass of ferro-dolomite in varying direction. Very often, in fact nearly always, the entire mass of ferro-dolomite is a perfect network of quartz veins, large and small, with masses and stringers. Sometimes the smaller veins have a radial arrangement about a larger nucleal mass, branching out from it like the spokes of a wheel, though without any regularity as to separating distance.

The quartz being much harder than the dolomitic rock, has been better able to withstand erosive agencies, and as a consequence often forms wall-like outcrops of dazzling whiteness, conspicuous objects in the picturesque landscape. These huge outcrops of ferro-dolomite and quartz frequently appear as conical hills in the centre of the mountain valleys, or as ridges rising above the general level of the adjacent country. Among those of the first mentioned type are Mount Ophir, and Penon Blanco (white cliff), in Mariposa county; McAlpine hill, and Quartz Mountain, in Tuolumne county, and Carson hill, in Calaveras county. Typical ridges formed by the great ankerite and quartz vein are those near Coulterville, in Mariposa county, and Golden Rule Hill, Whiskey hill, and the Rawhide hill, in Tuolumne county. Numerous outcrops of the same material appear elsewhere, but usually these merely form a portion of a group of hills or ridges, not being particularly conspicuous. Outcrops of this material also occur in the northern part of Calaveras county, near San Andreas, and in Amador county, in the town of Jackson, where it outcrops for nearly a mile and then disappears to reappear in El Dorado county, nearly 20 miles away. There are several long intervals of this kind along the Mother Lode where the dolomitic vein is not seen for miles, though quartz veins are of frequent occurrence in these intervals, being in schists or slates.

Throughout the entire length of the Mother Lode, wherever the ferro-dolomite is found, it presents essentially the same characteristics, one of the most important of which is the almost constant occurrence of a bright-green micaceous mineral called mariposite. The colour is due to the presence of chromium, and not to copper, as was supposed in early days, considerable work having been done then on some of the claims in the belief that the ore was rich in copper. Serpentine very commonly occurs along the Lode, in irregular intrusive masses often of great size, and it is in the proximity of the serpentine that the mariposite is most abundant. There are large masses of dolomitic rock, however, in which little or no mariposite is visible. While the serpentine does not always accompany the dolomitic vein, it occurs at many places along the Mother Lode where no sign of the dolomite can be found. As a rule, however, they are both found in the same localities.

Aside from their geological interest, the economic features of these occurrences are of importance. In most of the mines the dolomitic mineral is auriferous, the gold occurring in both the "free state," and intimately associated with pyrite. It is usually more abundant in that which is intersected by numerous veinlets of quartz, but the dolomite is itself gold-

*Mining engineer, 2437 Hilgard Ave., Berkeley, Cal.

Rawhide Mine, Tuolumne County, California

bearing when little or no quartz can be seen. In value these ores range from the merest trace of gold up to thousands of dollars per ton. In the Rawhide mine, near Jamestown, in Tuolumne county, was found a shoot of ankerite a great deal of which contained from ten thousand up to over twenty thousand dollars per ton in gold. These were not hand specimens, but tons of astonishingly rich ore. Similar ore has been found in the App mine, at Quartz Mountain, about three miles south of the Rawhide. It is scarcely probable that these two instances are the only occurrences of rich ankerite along the Mother Lode. In many places the mineral constitutes pay ore, and in some of the mines it is the chief source of the gold. The quartz so commonly associated with the ferro-dolomite is usually gold bearing in all of the mines in which it occurs, but like its occurrence elsewhere, it is by no means always rich.

As to the origin of the dolomitic veins, there seems to be no doubt (as far as the California occurrences are concerned), that they are the result of the alteration of ancient basic dikes which were intruded into the slates and schists in which they are now found, and in most instances they are undoubtedly older than the other dike-rocks with which they are associated. These intrusives are principally diorite, diabase, various phases of granite (chiefly aplite), serpentine, and gabbro. It seems not unlikely that these great masses of ferro-dolomite may have originally been gabbro, or some similar rock. There are many instances along the Lode where the gabbros have been altered to serpentine, every stage of transition between the two rocks being found, but the serpentine for most part has evidently been derived from peridotitic rocks.

It is well known that a lime-magnesian carbonate, and a lime-iron carbonate associate themselves in many proportions to form ferro-dolomite, and for this reason the dolomitic lode presents many phases. In some instances the outcrop consists of great masses of red and brown iron oxide and quartz, as at the Pine Tree mine, in Mariposa county, and at Quartz Mountain, in Tuolumne county, while in other localities it appears as a gray, lustreless mass, with little sign of the presence of iron in any form. Again, it is bright and "lively," filled with scales of mariposite and minute veins of quartz. Usually the rock is rather coarse in texture, occasionally fine-grained, sometimes dull, sometimes glistening, like the surface of new fractured marble.

Too little careful study has been given to the origin and the subsequent alteration of these great dolomitic masses, and we still have much to learn concerning them. Investigation of these deposits has thus far been almost wholly confined to the economic features, and it is, after all, the economic phase that makes the proposition attractive, for this succession of outcrops of ferro-dolomite and quartz constitutes one of the largest, and in many respects, one of the most interesting series of auriferous deposits in the world.

COAL AND GOLD ORES.

Coal and gold ores are not often found in close proximity, but the Rand is a notable exception. In the shallower portion of the Far Eastern Rand, between the Apex mine and the Welgedacht, the coal measures are found near the surface, and are underlaid by the auriferous banket beds. The coal measures also contain a small percentage of the yellow metal, and many years ago an attempt was made to recover this gold from the ashes. The recovery was, however, very small as to be unpayable. At the Buffelsdoorn mine a small seam of coal was found in the banket beds.

SUGGESTED AUSTRALIAN EXPORT DUTY ON ORES.

For some time there has been an agitation in Australia for an export duty on crude ore, the contention being that the dear labour and high railway rates in Australia prevented the local smelters from successfully competing with foreign smelting works. An export duty would, it is contended, mean an increase in supplies to local works. But it would be adverse to the outlying districts, such as Whim Well. This mine, being near the seaboard, can ship its ore at a cheaper rate to European smelters than it would cost to ship to the smelters in New South Wales, and it costs much less to smelt on this side than in the colony. An export duty would, therefore, be such a burden on some mines that it might compel them to close down entirely.

McIntyre - Porcupine Mines, Ltd.

(Written for the CANADIAN MINING JOURNAL by V. H. Emery).*

[illegible]e general location of the above property may be see[illegible] in the accompanying map, fig. 1, which is a reproduction on a small scale of a survey made of the district surrounding Pearl Lake. The map shows the location of the quartz outcrops, and the direction of the general strike of the veins in the district.

Geologically the McIntyre is situated in the much de[illegible]ed quartz-porphyry zone, which, as is shown in fig[illegible]1, passes from the Hollinger through to the east en[illegible] of Pearl Lake, the strike of which corresponds al[illegible]ost exactly to that of the veins. This quartz-porphyry intrusion has been greatly metamorphosed by pressure, giving it a schistose appearance, and in some places becoming quite talcy. At the south of this intrusion the rock is an amygdaloidal basalt, while in the north it is chiefly composed of basalt commonly called green-stone.

The surface development of the McIntyre may be seen in part by the accompanying photographs. A 12-drill compressor will be in operation by the first of September. The contract for a forty-stamp mill has been let, a portion of which it is proposed will be used for customs work for some time. The general process

General View McIntyre Camp, Porcupine.

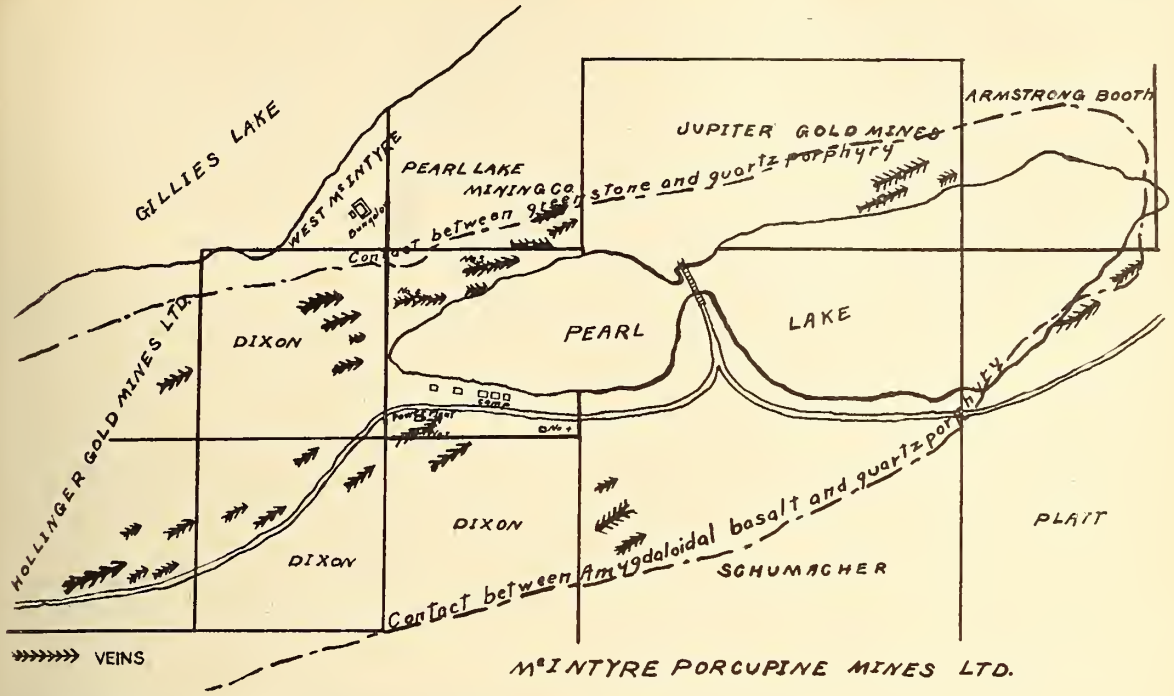
[illegible]ining Engineer, Porcupine, Ontario.

Large Vein Uncovered on Dixon Line Running Into McIntyre.



McIntyre No. 2 Vein, Showing Dump.

of treatment of the ore will be amalgamation followed by cyaniding.

Considerable underground work has been done. Four shafts have been sunk on veins to depths from 75 to 100 feet, all of which have developed high grade ore. About 1,000 feet of drifting and cross-cutting have also been completed, which has in some instances opened up extremely rich ore shoots.

Two shot drills have been working continually since operations commenced, and a diamond drill for the past two months. In all nine holes have been drilled, some to considerable depths the result of which has been very encouraging. Large high grade ore bodies have been located at depths both under the lake and on the land property.

When the compressor commences operating, development work will be carried on at a very rapid rate, accompanied with systematic sampling, a thing that is essential in this district for determining the extent of pay rock in the schist, which in some instances extends from one quartz vein to another.

It is expected that by the time the mill is ready to receive ore that sufficient of the ore now located will be in readiness to keep it running at its fullest capacity.

THE SEARCH FOR PROMISING MINES.

Mr. Sidney J. Jennings, the vice-president of the United States Smelting, Refining and Mining Company, has stated that in the year 1910 an examination of the reports submitted resulted in the rejection of no fewer than 514 mining properties. A preliminary examination was made on 124 properties, with the 46 properties only was further work done, but only two of these were found sufficiently attractive to warrant purchase. These figures show the trouble involved in finding a suitable mine, and the large expenditure necessary to do so.

A Visit to the West

(Special Correspondence.)

As I have just returned from spending a month in southern Alberta and western Saskatchewan, where I had occasion to look into the local coal situation, I have jotted down a few notes that may be of interest to your readers.

Glancing first at the prairie deposits, it is well-known, of course, that the coal of these regions is a low-grade bituminous fuel, in most places resembling closely the product of the Lethbridge mines. Further west, in the Crow's Nest Pass country, the coal is of distinctly higher quality.

The growth of the agricultural industry is so pronounced that land for from 50 to 100 miles surrounding the present lines of railroads is taken up by farmers. Hence the need of local fuel supplies is becoming more and more pronounced; and the country is being prospected systematically. The result has been the discovery at numerous points over the southern Alberta prairies of outcrops of coal, usually in the bottoms of the coulees. In thickness the seams run as high as 9 feet. They are practically flat, and should be easily worked by tunnel from the outcrop.

These discoveries give some idea of the extent to which the prairie is underlain by coal measures. No doubt, deposits could be located at many points by shaft, if local conditions warranted the expense.

The point of my remarks is, however, that farming on a large scale, implying the use of steam-driven machinery, is creating a large demand for cheap fuel. Steam and gasoline engines are being used extensively already to break the land. The farmer pays as much as $15 per ton for coal laid down at the farm. Seldom does he pay less than $10 per ton for coal distributed by rail from the Lethbridge and Taber districts, and then hauled by team to the farm. Coal from Fernie and Cranbrook costs correspondingly more.

In some cases the farmer or rancher owns the mineral rights as well as the surface. In all cases a lease on the coal rights can be secured. Thus many farmers are producing coal on a scale sufficient to meet the requirements of themselves and of their immediate neighbours. Local sources of supply mean a saving of from 50 to 75 per cent. in the cost of fuel. Incidentally, the steam traction engine is more popular than the gasoline traction, because it is decidedly more fool-proof. It will be used exclusively wherever cheap coal can be obtained, and will replace the horse to a very large extent. The gasoline traction engine, on the other hand, is a constant source of trouble. The expense bill is so high that it is doubtful if the most competent mechanic can operate them to commercial advantage. Supplies and repair parts are exceedingly difficult to obtain, and the engine is apt to be put out of commission at any time.

It is probable within a few years many small coal workings will be opened all over the western prairies. Coal thus produced is always cheaper than that brought in by rail from the larger mines.

* * * * *

On my way east I stopped for a few days near the Manitoba-Ontario boundary to examine and report upon a gold mining property that has been quietly developing during the past two years. I would like to point out that in the excitement of eastern booms we are all apt to overlook the west. Western Ontario and eastern Manitoba are worth looking over. Study of coal conditions in Alberta and Saskatchewan is very profitable. In all of these districts there are many excellent chances for investment.

W. E. H. Carter
*Mining Engineer, 85 Front St. East, Toronto.

Electrothermic Smelting Zinc Ores.

On two or three occasions Hon. Wm. Templeman, Dominion Minister of Mines, has publicly mentioned that in connection with the experiments being carried on by the Mines Branch of the Canada Department of Mines in the reduction of zinc ores he has "secured the services of W. R. Ingalls, of New York, who is said to be the greatest expert in zinc on the continent." Mr. Ingalls, who is editor of The Engineering and Mining Journal, New York, contributed to the annual meeting of the Canadian Mining Institute held last March a paper on "The Problem of Mixed Sulphide Ores." The text of this paper was printed in The Engineering and Mining Journal of July 29. The following excerpt from Mr. Ingalls' paper is here given. After dealing with various methods of treatment that had been tried, Mr. Ingalls continued:

"For those places where it is desired to develop a market for miscellaneous ores, a place to which any miner can send and sell small outputs, or even an occasional lot of ore, it seems to be necessary to develop some system of pyrometallurgical concentration, or what may be roughly characterized as smelting. This idea is under consideration in some experimental work that is now being done by the Department of Mines of the Dominion of Canada. Along with that work, attention is also being directed to the subject of electrothermic smelting.

"The possible treatment of zinc ores in the electric furnace is not a new idea. Attempts to smelt zinc ore in such a furnace have been made from time to time during the last 25 years. In fact, the Cowles brothers, who achieved distinction in connection with the aluminum industry, were engaged in an attempt to smelt zinc electrically before they directed their attention to aluminum. The list of proposals for electrothermic smelting of zinc is almost as long as those for the blast-furnace smelting of this metal, and those in the field of hydrometallurgy. At least two ambitious attempts at electric smelting on a commercial scale have been made. Both were failures, not only commercially, but also metallurgically. I am disposed to think that such metallurgical difficulties as have been experienced in the electric smelting of zinc ores can be surmounted, but even with this assumption I am by no means prepared to say, at the present time, that electric smelting would have any advantage over smelting in the standard way. My present view of electric smelting isofar as zinc is concerned, is simply that it is an unexplored field of metallurgy. In ploughing this field we may find something of value, but as to whether we shall or shall not we cannot at present say."

Tentative Program and Rules

First National Safety Demonstration.

Under auspices of U. S. Bureau of Mines, American Red Cross Society, and Pittsburg Coal Operators' Association.

Non-competitive exhibition of skill in first aid to the injured in mines, to be held in Forbes Field, Pittsburg, Pa., October 27, 1911, 9 a.m. to 1 p.m.

Not more than one team of five men to represent any one coal mine, or the U. S. Bureau of Mines, or state mine departments, provided that coal mining companies operating more than one mine may enter additional teams representative of groups of miners, veners, trapper boys, or other mine workers.

All persons entering to submit certificates showing that they are, or have been, bona fide mine workers.

All entries to close one month prior to date finally elected for the meet.

Coal companies entering teams to be invited to present, not later than one month in advance of meet, a list of five events as their choice, these to be submitted to the managers, who will select five for adoption from the various events suggested, each entering team to exhibit in those events suggested by them and such others of the five as they may elect. All teams to exhibit in unison.

Should any unusual or valuable events be suggested, the managers may increase the program by one or two such special stunts.

In addition to the five first aid events there will be a representation of a coal dust explosion, with rescue by helmetmen and first air treatment.

Exhibition of skill in adjusting and use of rescue apparatus by teams of four with a captain; entries to be as above for first aid teams.

Exhibition in use of fire extinguishers upon a fire by members of the rescut crews.

9. Souvenir badges of the American Red Cross, souvenir buttons of the U. S. Bureau of Mines, and souvenir programs to be presented to individual entrants; a souvenir first aid box to be presented to each team entering; a souvenir pennant with the name of the company sending entrant, and to be used on the field as a marker, to be presented to the company represented.

1. There will be introductory remarks by the Director of the Bureau of Mines and a member of the Executive Committee of the American Red Cross.

2. Presentation of souvenirs will be made at the close of the exercises in brief addresses by speakers of national repute.

Le Roi Mining Co. in Liquidation.

A meeting of shareholders in the Le Roi Mining Co., Limited (in liquidation), was held in London, England, on July 14 "to consider an offer which the liquidator has received for the purchase of the Canadian assets of the company." The Financial News' report of the proceedings follows:

Mr. A. J. McMillan (the liquidator), who presided, said that since the company went into liquidation last September he had been in negotiation with various parties in England and in Canada, but the offer made by the Consolidated Mining and Smelting Company of Canada, Limited, whose headquarters are in Toronto, Ontario, to purchase the Le Roi Company's Canadian assets for $250,000, was the best he had received, and he recommended that it be accepted. The offer provided for the payment by the Consolidated Company to the liquidator of the Le Roi Company of $250,000 for the Le Roi mine and the mineral claims adjacent thereto owned by the Le Roi Company, together with the machinery, plant, ore dumps, water rights, and real estate also owned by the company. That purchase price did not include cash on hand at the close of business on May 31, 1911, nor accounts receivable as on that date, both of which would be retained by the Le Roi Company, while the mining stores and supplies on hand at the mine were to be taken over by the purchasing company upon a valuation.

The purchase money would be paid as follows: Within 48 hours after the receipt of a cable advice of the ratification of the sale — which cable he proposed to transmit that day if the meeting confirmed the sale —the purchasing company would, for the purposes of that agreement, pay into the Dominion Bank, in Toronto, the sum of $25,000, and upon acceptance of a title a further sum of $100,000 would be paid into the same bank for transmission to the credit of the Le Roi Mining Company at par of exchange. At the expiration of one year from the date of ratification the balance of $125,000 would be payable, together with interest thereon from the date of ratification at the rate of 5 per cent. per annum, the purchasers having the option of making the final payment at any time after acceptance of title, with interest from the date of ratification to the date of such payment. These were the essential features of the agreement.

They would notice that the company's smeltery at Northport, Washington, and assets connected therewith, were not included in the terms of sale. Efforts were being made to dispose of that property, but up to the present time no definite offer had been received for it. It was impossible, therefore, to at present say what might be derived from the sale of the remaining assets of the company; but he was doing his best to dispose of them to advantage.

There was not very much to say in regard to the subject under consideration, and he did not think it really admitted of much discussion. While the price was not a large one, when compared with the original purchase price paid by the late Mr. Whitaker Wright or under his auspices, it was the best offer he had received, and, in his opinion, it was the best the shareholders would ever receive, so he advised them to accept it.

Mr. Grinke-Drayton, the late chairman of the company, having first remarked that he was satisfied the shareholders would never get a higher offer for the property, moved that the same be accepted.

Report of U. M. W. of A. Executive

The Executive of District No. 18, United Mine Workers of America, in which district are all the local unions concerned in the strike of miners and other coal mine employees in southeastern British Columbia and Alberta, issued under date July 29, a report addressed to the officers and members of local unions in District 18. After dealing with other matters relating to the lack of agreement between the members of the U. M. W. of A. and the Western Coal Operators' Association, the report gives a table showing the differences between the rates paid by the operators to the miners under the agreement that expired on March 31, last, and those that would be paid according to scale recommended by Dr. C. W. Gordon, chairman of the Board of Conciliation and Investigation, and that by Mr. A. J. Carter, the member of the board who represented the employees and who presented a minority report. The following part of the report of the executive will be of more general public interest:

"Reviewing the report of Dr. Gordon generally, as affecting the wages of our members, the advantages granted on the low rates would be offset by the reductions made on contract rates on pillars, leaving the majority of our members in the same position as heretofore, notwithstanding the many changes that have occurred, adversely affecting our wages, that were forcibly drawn to the attention of the board.

"In replying to the communication of the Minister of Labour we stated that we were prepared to make an agreement on the basis of Secretary Carter's report, and have, up to this time, steadfastly refused to consider an agreement on the basis of the report of Dr. Gordon. Our specific reasons for taking this position are:

"1.—That the advance suggested on the day wage scale is not what we are entitled to, and is only offered as a compromise, and in conjunction with the reductions specified.

"2.—That we do not consider that we should at this time submit to any reductions.

"3.—That no advance is granted on contract rates generally.

"4.—That no recommendation is made regarding the General Provisions of Agreement.

"It would be well in considering the action to be taken to carefully review the position of the District as it is after the suspension of four months.

"Up to this time, no attempt has been made to operate the mines without recognizing the organization but the members must be prepared for such a contingency, as this will undoubtedly be done, if the operators can force a guarantee of protection from the government.

"The action of the Boards of Trade delegate meeting at Macleod points in this direction, and gives in addition, an example of what might be expected from the particular portion of the community they represent.

"We are still of opinion that with continued firmness on our part we will be able to arrive at a better agreement than has governed us during the past few years, and we would like you to give this matter your earnest consideration from all standpoints before rendering a decision."

In addition to circulating the report from which the foregoing extracts have been made, the Executive of District 18 sent representatives to address the miners in some of the larger centres. A press despatch dated Fernie, August 11, published in the Nelson Daily News gave figures showing the result of the voting for and against acceptance of the recommendations of the chairman of the Board of Conciliation. The ballot of 17 local unions resulted in an aggregate vote of 393 in favour and 2,240 against acceptance. Returns had not been received from Coleman and Canmore, but these cannot materially affect the position. As more than half the votes were recorded at British Columbia collieries, figures from those follow in detail, while those from Alberta are given in totals only:

Places.	For	Against
Fernie	105	583
Michel	60	433
Hosmer	50	130
Corbin	3	46
In British Columbia	218	1,192
Alberta (13 locals)	175	1,048
Aggregate of votes	393	2,240

A Suggestion about the Treatment of Porcupine Ores

(Written for the CANADIAN MINING JOURNAL by Phil H. Moore.)*

Although at the present stage of the mining excitement in the Porcupine gold fields, more attention has been given to the finding of gold-bearing rock than has been given to the process of recovering the gold from the rock, it is inevitable that within a comparatively short time the milling of Porcupine ores will be the chief problem that the mining engineers will have to solve. In the case of the Dome and Hollinger mines the engineers in charge have evidently had it in their minds that considerable experimenting will have to be done on Porcupine ores before they could take the final steps in designing larger and more permanent milling plants. Hence the comparatively small installations that are now going into these extensive and valuable mines.

In many cases it is neither convenient nor expedient for the smaller mines to wait until the larger companies have demonstrated what really will be the best treatment of Porcupine ores. With an idea of helping out the engineer that is in charge of a comparatively small proposition but who sees sufficient values in sight to warrant the building of a small plant, where it is even more important to save all the values possible in

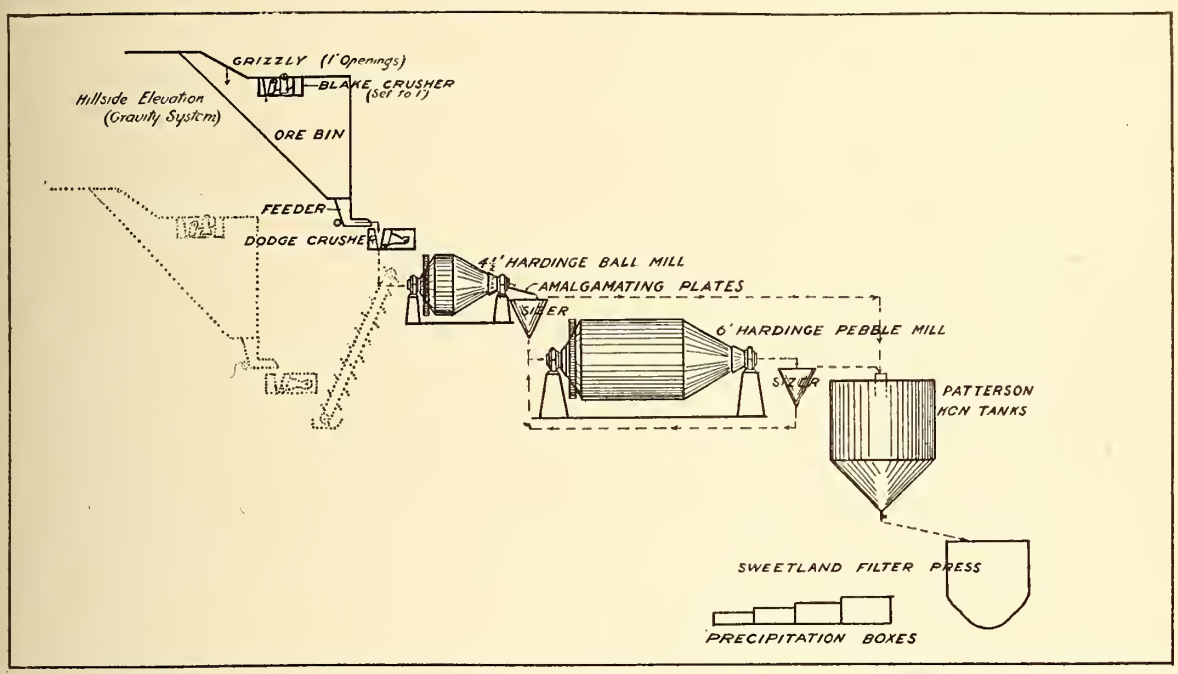
*Mining Engineer, King Edward Hotel, Toronto.

ore, than it is in a large, I have prepared the flow t accompanying this article.

his flow sheet has been prepared after making care- tests of Porcupine ores, and after investigating carefully the performance of the machines and aratus included, and deciding that they are the efficient machines on the market that have come in my notice.

s will be seen by the flow sheet, the ore to be ied is dropped through a one inch grizzly, and the -size goes to a Blake crusher set to one inch. The duct from the 1-inch grizzly and from the Blake her goes to an automatic feeder and into a Dodge her that reduces the product so that it will pass ree-quarter-inch ring. This in turn is fed into a foot Hardinge ball mill, which reduces the rock hat it would pass a 20-mesh screen. Owing to the cal shape of this machine, however, a screen is not l, and by the elevating or lowering of the discharge the product from this mill can be regulated to any desired. The product from the Hardinge ball sumed, and maintenance expense. One 4½-foot Hardinge ball mill will do the work of 15 stamps, but costs one-third less and requires no heavy foundation and less power to operate. The same applies to the Hardinge pebble mill when compared to the old fashioned square ended tube mill. The fact that these mills require no screen, is in itself no small item in operating expense.

The Patterson agitation tank is an improvement on the old style Pachuca agitation tank. In a fifty to seventy-five ton plant such as the flow sheet calls for, it will probably be necessary to use three of these tanks. The product passing from these tanks into a thickening tank would then pass direct to the Sweetland filter press, which is a pressure and not a vacuum machine. This press is the nearest thing to an automatic filter press that the writer has been able to find on the market, and sufficient demonstrations have been given, and sufficient testimonials are available so that the writer has adopted the press as being the best thing on the market at any price. And hence it



Flow Sheet of 50-75 ton Amalgamating & Cyanide Plant, furnished by P. H. Moore, King Edward Hotel, Toronto, Ont. Note : Dotted lines indicate Flat Elevation (Elevator System)

l passes over an amalgamated copper plate. From th experience of J. M. Elmer, of Tuolumne, California, a many others, it is believed that quicksilver may b introduced into both ball and pebble mills of the Hardinge type without flouring, in some cases sodium amalgam being used. In the writer's opinion it will b unnecessary to introduce mercury into the ball mill, as with a well amalgamated copper plate all of the coarse gold that leaves the Hardinge mill will be caught b fore the pulp leaves the plate and the finer values carried by this pulp will be caught in the cyanide proces following. The material passing over the copper pl te will go into a sizer the over-size passing into the Hardinge pebble mill for sliming, and the undersize p sing direct to the Paterson agitation tanks. The w ter is not allowed space to go into the merits of th Hardinge type of ball and pebble mills. But it suffices to say that on account of the conical shape of th se mills they are in the writer's opinion the most efficient machine, considering first cost, power con- is suggested in the flow sheet. When it comes to the precipitation of the gold carried in the solution taken out of the slimes, undoubtedly the zinc dust process is more up to date than precipitation on zinc shavings. I suggest that the cyanide solution should be introduced into the Hardinge pebble mill and carried through the entire process. A preliminary agitation would thus be given to the pulp while in the process of being slimed in the pebble mill.

In a few words, it is the intention of the writer to convey the suggestion that the treatment of Porcupine ores may best be simplified by treating the ore from the start with the intention of sliming the entire product, paying but little attention to the recovery of the gold in the earlier stages of the process. As it is necessary to treat the tailings from a stamp mill or other crushing agent by the cyanide process, it seems entirely unnecessary to divide these tailings into "sharps" and "fines," as this would require two separate treatments. Also it seems unnecessary to at-

tempt to make a high recovery by amalgamation. The writer would suggest that in case of certain ores heavy with concentrates, an additional concentrating plant could be added without much cost, and these concentrates might be treated with bromo-cyanide at slight cost per ton.

The cost of the entire plant as shown in the flow sheet should not exceed $25,000, erected in the Porcupine district, providing the haul was not too great from the railroad. The above sum includes the necessary steam boilers, engines, and pumps. Or, in case of electric power being available, the necessary motors to run the plant. A 60 h.p. will be all the power required. 90 per cent. of the total gold contents of the ore should be saved by this process, at a cost not exceeding $1.50 per ton.

An Enormous Deposit of Coal

Occasional reference has been made to the great size of the deposit of coal the Corbin Coal & Coke Company, Limited, of Spokane, Wash., U.S.A., has during the last three years been engaged in opening in the southeastern part of the Crow's Nest district, East Kootenay, British Columbia, but no conception of its astonishingly large proportions has been generally obtained. One principal reason for the comparative lack of information in regard to this altogether unusual occurrence of coal is the fact that the Corbin Company has avoided publicity. Nevertheless it is a fact that a phenomenally large body of coal is being explored, though as yet without any clear idea of how big it really is, development work not yet having reached the limits of the coal.

In response to an appeal for information, Mr. E. J. Roberts, of Spokane, managing director of the company, lately showed our British Columbia correspondent blue prints of the plan of surface workings and gave him particulars, of which the following is only a brief summary: The mine that has during the last two years been producing coal is at a comparatively low elevation—about 500 feet above the tipple. The main entry here has been driven approximately 2,000 feet and the coal deposit found to be at its widest part fully 300 feet in width. Farther in it has narrowed considerably, what appears to be a large point of rock having come into the coal. Development work is not being continued here, however, for there is so much coal available that the driving of additional length of entry would only involve maintenance costs that are quite unnecessary so long as the further opening of the coal body in that part of the property is not required.

At an elevation of about 1,200 feet above the main entry, on Coal Mountain, there occurs what is known locally as "the upper big showing," About 400 feet lower down the mountain, or 800 feet above the main tunnel, there is another big outcrop of coal, known as "the lower big showing." During the last six months these "big showings" have been partially prospected. An underground cross-cut shows the coal of the upper showing to be 96 feet in width where prospected by this working. Analyses of every 10 feet of coal give the following average percentages for 12 tests: Moisture, 0.87; volatile combustible, 18.47; fixed carbon, 67.86; ash, 12.80. The highest results were from the sample taken from the last 9 feet of coal cut in this tunnel, namely: Moisture, 0.45; volatile combustible, 15.70; fixed carbon, 77.40; ash, 6.45.

The lower big showing has been cross-cut by an adit which at 370 feet from its portal entered slate rock. Analyses, 37 in number, gave the following general average percentages: Moisture, 0.73; volatile combustible, 20.03; fixed carbon, 64.25; ash, 15.00. The highest results were from coal cut between 20 and 30 feet in from the portal of the adit. They were as follows: Moisture, 0.60; volatile combustible, 22.49; fixed carbon, 68.31; ash, 8.60. This lower showing has been cut in pits sunk through the surface wash deep varying down to 15 feet, and the vertical depth of the underground working where it reached the slate is approximately 200 feet below the coal cropping cut in the pit immediately above it.

This enormous deposit of coal continues to be a problem to those engaged in exploring it, and much more development work will be necessary ere it can be understood. The fact remains, however, that there is a great quantity of bituminous coal of excellent quality, occurring under conditions that will admit of its being mined at very low cost.

CANADIAN MINING INSTITUTE — WESTERN BRANCH.

The eleventh general meeting of members of the Western Branch of the Canadian Mining Institute will be opened at New Denver, Slocan Lake, B.C., on Wednesday evening, September 13, 1911, when routine business will be transacted and several papers, some having particular reference to the mining industry of the Slocan district, will be read and discussed.

All members of the Canadian Mining Institute in good standing resiring in Western Canada and the neighbouring parts of the United States are, by virtue of such membership, also members of the Western Branch. Members are earnestly requested to make every effort to attend the ensuing meeting, and are cordially invited to contribute papers on matters relating to mining or metallurgy for reading at it; also, to inform the secretary that they will do so, if such be their intention.

Non-members will also be heartily welcome to attend, and to take part in the discussion of the papers that shall be submitted to the meeting.

The town of New Denver is situated on the eastern shore of Slocan Lake, which is one of the most beautiful lakes in the Kootenay district. For a pleasurable early autumn vacation the lake possesses the advantages of fine scenery, good boating, and fishing. Excellent hotel accommodation is obtainable. Local residents have offered to cordially co-operate to make a visit to their town and district thoroughly interesting and enjoyable. There are beautiful drives along the lake shore, and numerous launches are available for outings on the lake. Facilities will be afforded for visiting several important silver-lead mines and concentrating mills situated six to nine miles from New Denver. A short railway trip will take visitors into the heart of the Slocan Mountains and mining country.

It is requested that those who purpose attending the meeting — especially if to be accompanied by ladies —will please notify the undersigned, so that accommodation may be arranged for in good time.

E. JACOBS,
Secretary of Western Branch of C.M.
Victoria, B. C., August 12, 1911.

Coal Lands of the Hastings (B.C.) Exploration Syndicate, Ltd.

The Head Syndicate, Limited, a British organization of which Mr. James Head, of London, is chairman and Mr. Leslie Hill, of Nelson, B.C., is general manager and mining engineer, has for some time been continuously developing the southern portion of the coal lands of the Hastings (British Columbia) Exploration Syndicate, Limited.

These lands, which join on to the south end of the property of the International Coal & Coke Company, Limited, of Coleman, Alberta, comprise 6,520 acres, giving a total length of ten miles on the coal seams, with an average width of one mile on their dip. The area was originally located and purchased from the Government of Canada by the Hastings Syndicate and the Kootenay Supply Company, jointly. In 1909 the Head Syndicate was formed to purchase the interest of the Kootenay Supply Company and to develop the property. An option of purchase of the interest of the Hastings Syndicate is now held by the Head syndicate.

The conglomerate overlying the coal seams forms a continuous ridge from the International Coal & Coke Company's property to Lynx Creek, a tributary of the North Fork of Old Man River. The ridge rises abruptly from Lynx Creek and reaches a vertical height of 1,000 feet in a horizontal distance of 2,500 feet. The average vertical height above Lynx Creek for 8½ miles is not less than 900 feet, so that it is estimated there are at least 45,000,000 tons of workable coal above adit level. There are three seams of coal, averaging, respectively, 10 feet, 12 feet, and 15 feet in thickness. The coal is of similar excellent quality for coking and steam purposes as that for six or seven years mined by the International Company, and still being produced by it. The extent and continuity of the coal seams and the excellent quality of the soil, together with the large tonnage above adit level, combine to make this property one of the most important and valuable yet opened in Alberta east of the Rocky Mountains.

The Head Syndicate has established a substantial and comfortable camp near where Lynx Creek crosses the coal seams. Previous to 1909 the Hastings Syndicate and the Kootenay Supply Company developed the northern half of the property by means of open-cuts and cross-cut tunnels, and proved the continuity and regularity of the coal seams. The additional work since done by the Head Syndicate has shown that the seams of coal extend without a break for the whole distance—8½ miles—over which development has been done. Work now in progress includes driving a tunnel about 1,000 feet on the highest seam, and from this the other seams will be cross-cut.

A route for a railway line has been surveyed up the North Fork of Old Man River, this passing within four miles of the present mine workings. This railway, when constructed, will connect with the Canadian Pacific in Canada, and with the Great Northern Railway system in Montana, U.S.A. The construction of a branch line four miles, from the North Fork up Lynx Creek, will provide railway transportation facilities for the Head Syndicate's coal mine. The problem of transportation of coal from the mine to markets on both sides of the International Boundary line, is, consequently, a simple one, which is another distinct advantage to the property, the opening of which to a producing stage on a comparatively large scale is not likely to be much longer delayed.

Non-Working of Coal Mines Involves Heavy Loss

In the course of an interview with a representative of the Vancouver Daily Province, Mr. A. C. Flumerfelt, of Victoria, B.C., formerly actively associated with the management of the Granby Consolidated M. S. and P. Co., and afterwards president of the International Coal and Coke Co., operating in Alberta, in the eastern part of the Crow's Nest district, is reported to have said:

"I regret there have not been any recent developments which indicate a settlement of the unfortunate labour difficulties in Alberta and eastern British Columbia. The position is a serious one and can not be fully appreciated by those not directly interested.

"The actual loss to the miners and other employees by reason of their stopping work is about $20,000 a day. The suspension of work occurred on April 1, and has now lasted 85 days, which figures up a loss in wages of about $1,700,000. Apart from the loss sustained by labour, which also includes that caused by the reduction of train crews, there is an economic loss running into many millions, which can never be regained. Then, too, this has a very serious aspect when one contemplates the possibility of its continuance later on in the year, with the prairie provinces unsupplied with fuel. Surely this is a matter requiring the attention of the Dominion Government, as well as the Provincial Governments."

Terms of Settlement Recom'ded by Conciliation Board.

The Fernie "District Ledger," which is the official newspaper of District 18, United Mine Workers of America, in the course of its comments on the recommendation made by the Board of Conciliation before submitting its report to the Minister of Labour, says, in part:

"The proposed basis of agreement as summarized by the chairman is as follows:

"1.—Advance in day wages of 10 per cent. on wages below $3, 8 per cent. from $3 to $3.50, and 5 per cent. for rates above $3.50.

"2.—Differential in pillars of 5 cents to 7 cents, according to conditions. Application left to arbitration.

"3.—Contract rates to remain unchanged generally.

"4.—Advance in contract rate of 3 per cent. at Lethbridge.

"5.—Readjustment at Lille by making rate proportionate to seam.

"All other matters in agreement to be disposed of as the board shall direct."

The recommendations of the board were not accepted by either the operators or the representatives of the employees.

OBITUARY.

A familiar figure in the mining circles of eastern Ontario was removed by death on Tuesday, August 15th. Early on the morning of that day, William Arthur Hungerford passed away at his home in Madoc.

Mr. Hungerford was born in County Cork, Ireland, in 1847. When but 17 years of age he came to Canada. For some years he worked in London, Ont. The rush caused by the discovery of gold near Madoc attracted young Hungerford in 1868. This was his first taste of mining. For 27 years, with Belleville as his headquarters, Mr. Hungerford devoted a large part of his time to developing mining properties in Hastings county. His name is associated with the history of many gold mines in that region.

For the last five years of his life Mr. Hungerford lived in Madoc, where he took an active part in public life. His last venture was the organization of the Canadian Talc and Silica Company.

Upon the mining history of eastern Ontario Mr. Hungerford left a permanent mark. He was one of those rare persons who, although living in a district that attracts little public attention, yet manage by persistent effort to rouse the interest of financial men.

N. Ramsay Pennypacker, mining engineer, who died at Saranac Lake, N.Y., August 20th, in his 30th year, received his degree of Engineer of Minnes from Lehigh University. He was born at "Mt. Pleasant," Harford County, Maryland, and was named for his mother's forefather, Col, Nathaniel Ramsay, of the Maryland Line in the Revolutionary War. He had charge for a year or more of the mines of the Pennsylvania Feldspar Co., in Ontario. In 1907 he went to Nevada for Philadelphia capitalists and reported in favour of silver prospects at the place which became widely known as Rawhide. At that time Rawhide consisted of two or three tents. In a year 5,000 people were made homeless there by a fire. Afterwards he went to Cobalt for Philadelphians, and after investigation obtained an option on a prospect. The plants to complete the contract fell through by reason of his falling ill in 1909 with the disease from which he died two years later. This property soon showed rich native silver and was capitalized at a million and a half dollars. In 1909 he planned an expedition to the then new Porcupine district. One of his exploring party was Hollinger, who a short time later located the famous Hollinger gold mine. He was a son of Isaac Pennypacker, of Pennsylvania. He was a member of the Delta Phi fraternity.

Consolidated Mining and Smelting Co's Metal Production.

The tonnage of ore received and smelted at the Consolidated Mining and Smelting Company of Canada's smeltery at Trail, British Columbia, during the fiscal year ended June 30, and the gross value of the metals recovered therefrom are as follows:

Tons of ore (including concentrates) received during year, 392,751; tons smelted, 388,774; gross value of metals—gold, silver, lead, and copper—recovered therefrom, approximately $4,438,000. Of this gross value, 55 per cent. was represented by gold. The corresponding figures for the fiscal year ended June 30, 1910, were: Tons of ore smelted, 487,125; gross value of metals recovered, $5,911,767; proportion of gold to gross value, about 48 per cent.

The average prices of metals for the last fiscal year show little variation from those of the previous year. The company's last annual report gave the average quotations during the year ended June 30, 1910, as having been: For London lead, £12.921 per long ton; New York silver, 51.948 cents per oz.; and electrolytic copper, 12.981 cents per lb. Average prices for year ended June 30, 1911, as Engineering and Mining Journal quotations, were: London lead, £12,949 per long ton; New York silver, 53.696 cents per oz.; electrolytic co 12.337 cents per lb.

The tonnage of ore smelted at the Trail smeltery the gross value of metals recovered during all years the beginning of 1894 to June 30, last, were: smelted, 2,847,458; gross value of metals, $47,084 The respective quantities of metals recovered last are not yet available, but the next following fi show them for all years to June 30, 1910: Gold, 95 oz.; silver, 16,999,873 oz.; lead, 220,872,555 lbs.; co 43,453,814 lbs. Approximate figures of aggregate recoveries to June 30 last are: Gold, 1,100,000 oz. ver, 18,700,000 oz.; lead, 255,000,000 lbs.; co 48,000,000 lbs.

The ore receipts during the year under notice the various mines operated by the company will pro be found to have been about as follows:—

Mine.	
Centre Star group, Rossland	19
St. Eugene, East Kootenay (concentrate)	
Richmond-Eureka group, Slocan	
Phoenix Amalgamated, Boundary	
Queen Victoria, Nelson div.	
No. 7, Boundary	
Molly Gibson, Nelson div.	
Snowshoe, Boundary (leased)	
Sullivan, East Kootenay (leased)	
Total from company's own mines	3

The foregoing figures have been compiled, as cerns the last three months of the period under re from newspaper reports, so necessarily are subj revision. For nine months, to March 31, figures obtained at Trail some time since. Allowing th total from the company's own mines, as shown ab approximately correct, it would appear that the of custom ore and concentrates received during las was nearly 58,000 tons.

With regard to the decrease in tonnage of ore sm last year, as compared with that to June 30, 1910, ly, 388,774, as against 487,125 tons—while no inf mation has yet been made public by the company, i be pointed out that the larger part of the short attributable to the much lower tonnage of ore re from the Snowshoe mine, in Boundary district—8 tons, as compared with 182,383 tons in the pr year. The quantity of lead-silver concentrate re from the St. Eugene mine was about 8,000 ton than in the preceding year, but, on the other han Sullivan mine shipped last year 33,852 tons of ore, as against 6,704 tons to June 30, 1910. Then was less custom ore obtainable from several mines, which were deprived of milling and ra transportation facilities, some of them as a result destructive forest fires of last summer. Apart, th from the matter of smaller ore receipts, it may pected that one subject will be dealt with in the pany's report for last year, namely, that the po at the Centre Star group of mines at Rossland is now than in several years past, particularly in reg there being now available, in the War Eagle m this group, much ore containing a comparatively value in gold.

The Canadian headquarters of Mr. A. A. Hassa in future be Cobalt.

Industrial Section

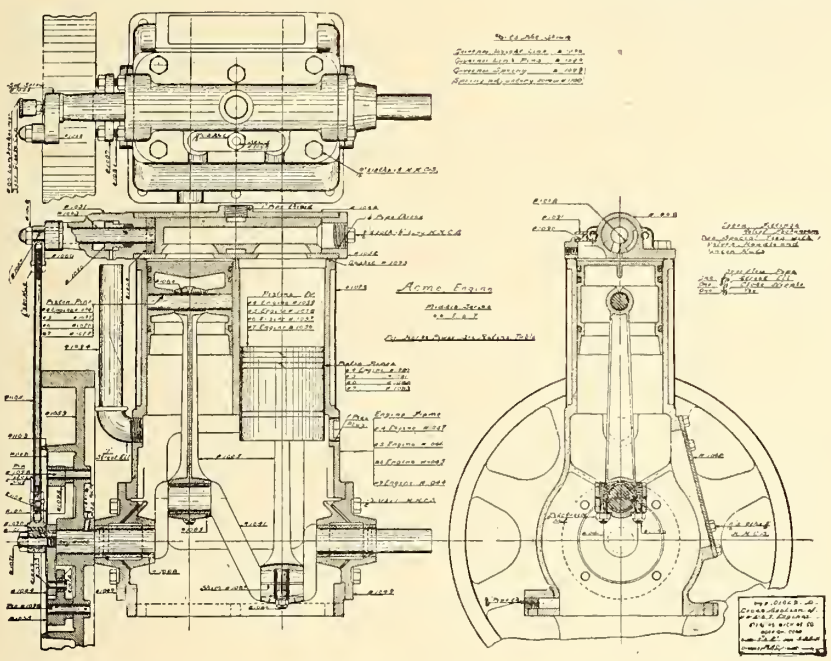
THE ACME STEAM ENGINE.

With the rapid growth and popularity of the gas engine, the impression has become quite general that the small steam engine is no longer an important factor in engineering fields.

This impression is entirely erroneous, so far at least as the experience of one of the largest manufacturers of small steam engines in this country goes. The mechanical stoker and similar advances in steam engineering have made the small steam engine indispensable. This is particularly true in plants where steam is a source of power, for in such plants the small steam engine proves an auxiliary which is very hard to equal both from the standpoint of economy and efficiency.

The Acme Engine, formerly manufactured by the Rochester Machine Tool Works, of Rochester, N.Y., and now by the Sterling Machine Company, of Norplicity of construction, the type of valve which adjusts itself to wear, the large bearing surfaces which are thoroughly lubricated at all times by a splash of oil, they are especially suited to drive mechanical stokers, for direct conection to small gear driven pumps, for driving rock drills and small friction hoists, and any variety of belt or direct driven pumping machinery for contractors or irrigation purposes.

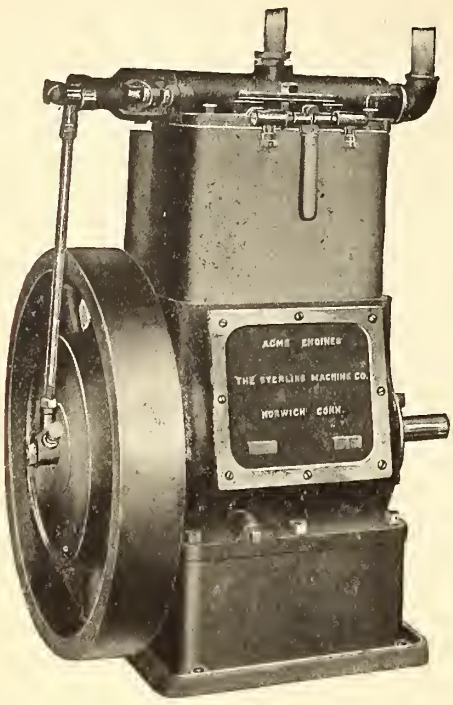
The character of internal construction is especially interesting, showing as it does the influence of automobile engine practice in many of the details. For example, the crank shafts are drop forged and ground to very accurate size, the connecting rods are of the popular I-beam section, bushed with bronze at both ends, the bearing cap on the crank end being held in place by castle nuts and cotter pins as is common in automobile work, the piston rings are of the diagonal cut type, two being placed above the wrist pin and



wich, Conn., is one of the best known small steam engines on the market. It has been manufactured for the past twenty years and improved from time to time to meet the demands of the day for a strong, simple, and economical unit.

The manufacturers have recently added several interesting features to this engine and a general description is given herewith which it is hoped will prove interesting to the readers of this paper.

These engines are of the vertical 2-cylinder single acting enclosed type with a balance rocking valve and are splash lubricated. They are built in three series of sizes, the small series being 2 1-8-in, 3-in., 3 5-16-in., by 1-2-in. stroke. These small engines are identical in external appearance. The middle series is 3 5-16-in., 4 in., 4 9-16-in., 5-in. x 5-in. stroke. These four sizes being also identical in external appearance and practically of the same weight. The large series of three engines is 5-in., 6-in., and 7-in., being also of the same external size and general appearance. This range of sizes covers all the applications to which these engines are especially adapted. Because of the extreme simone below. These rings are re-turned after cutting and ground to accurate size. The valve is a simple one-piece casting which is ground on the outside to fit a very accurately bored chamber and is fastened to the extended valve stem with a cross key in just the same way that the ordinary Corliss valve is fastened. A further point of considerable interest is the matter of automatic cylinder relief valves which are built into the cylinder heads to relieve any water that might otherwise cause damage. The governor is of a very simple type, consisting of four main pieces. The action of the weights being modified by means of a hardened roller which travels in a milled arc. The entire governing mechanism is contained in an oil pocket, only the pin to which the lower end of the valve rod is connected being extended through, and further, inasmuch as this mechanism is on the outside of the fly wheel, it is very readily gotten at. There are but two grease cups requiring attention, all other surfaces being amply lubricated by the internal splash. Provision is also made in the base of the engine for the elimination of the condensation which may collect and



the leakage from the valve stem stuffing box falls down into the engine base through the vent pipe at the end of the engine. The entire series of engines are built with new and accurate jigs on the interchangeable plan.

Exhibit of Jones and Glassco.

At the Canadian National Exhibition, held in Toronto, the firm of Jones & Glassco has an extremely creditable exhibit.

It would take up too much space to describe this exhibit in its entirety. But some salient features deserve special mention. Amongst these is a rotoscope fitted with a Renold chain, 1-inch pitch, 2½-inch wide, driving from a pinion to a wheel in which provision has been made for easy examination of the chain. A variable speed motor is used, making it possible for the chain speed to be varied from 700 F.P.M. to 200 P. M.

There will also be installed in action a chain-drive operating a fan. Moreover, in an elaborate machinery show case about 8 feet square, and 12 feet high, practically all the types of chains manufactured by Messrs. Hans Renold, Ltd., will be exhibited, along with specimens of special spring sockets, etc.

In addition, there will be in operation a centrifugal machine manufactured by Watson, Laidlaw & Co., Glasgow, and a complete exhibit of the cotton driving rope turned out by Messrs. Kenyon & Sons.

INDUSTRIAL NOTES.

From the Jeffrey Manufacturing Company, Columbus, Ohio, we have just received a Bulletin (No. describing their Single Roll Coal Crusher. The growing demand for screenings is so large that in many places lump or runofmine has to be reduced to a smaller size. The Jeffrey Single Roll is capable of reducing lump coal to any size required. The manufacturers claim that it cannot choke, that it will start under full load, and that, in a single operation, it will reduce lump to stoker size. The crusher can be supplied on trucks with motor drive attached. In design it is simple, and easily repaired.

The Apex Mining Co., Porcupine, has purchased from Mr. Phil. H. Moore a Class A McKiernan-Terry shot drill. Also the Miller Lake-O'Brien mine has purchased a similar drill. A Class B drill, capable of drilling 1,500 feet, has been acquired by Mr. Alex Miller for the Scottish Ontario mine at Porcupine.

The Robb Engineering Co., Amherst, Nova Scotia, and South Framingham, Mass., has recently received an order from the Sturgeon Lake Development Co. of Toronto, for two Robb-Mumford boilers, 54-inch by 18-foot, and one stack 48 inches in diameter and 80 feet high, with smoke connection.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

South Cape Breton Mining Society.

For many years the need of a mining society in Cape Breton has been apparent. The meetings of the Canadian Mining Institute, which are necessarily held in Quebec or Ontario, are inaccessible to the mining profession in Cape Breton. Owing also to circumstances which are unavoidable, there are very few members of the Canadian Mining Institute connected with coal-mining, and even of these the majority belong to the Western Branch. So far as distance is concerned, the meetings of the Nova Scotia Mining Society are almost as ungettable in Halifax, as the meetings of the C. M. I. in Montreal and Toronto. When it is considered that over a third of the entire Canadian coal output is produced in Cape Breton, it is evident that the lack of a mining society must have meant the loss of many valuable contributions to mining literature. For several months past a movement has been shaping itself among the officials of the two large Cape Breton coal companies to form a mining society, and this has at length taken definite shape. A society has been formed which will be known as the South Cape Breton Mining Society. The president is Norman McKenzie, the superintendent of No. District of the Dominion Coal Company, and the vice-president is J. C. Mitchell, manager of Dominion No. 6 colliery. The secretary is M. A. McInnis, superintendent of District No. The assistant general manager of the Dominion Coal Company, D. H. MacDougall, is the honorary president. The first general meeting of the Society was held in Glace Bay on the 19th of August, and took the form of a "smoker." With few exceptions, all the managers and underground managers of the Dominion Coal Company were present, together with representatives from the Sydney mines collieries, the department mine inspectors, and local notabilities. Although this meeting was only inaugural there was complete unanimity of opinion that the Society was very necessary, and the nucleus of a large membership is already assured. It is understood that four meetings will be held annually, and the next meeting will be for the purpose of reading and discussing papers.

It is to be hoped that eventually both the new society and the Nova Scotia Mining Society will become affiliated

Canadian Mining Institute in such a manner that, while ining their own individuality and management, and hold- their meetings at home, each mining society will subscribe ederated transactions, and get the benefit of all the mining pers read in Canada at a cost which would not be larger, and m be considerably less, than the cost of issuing separate tr sactions of meetings.

n addition to the benefits which will be derived from the p aration and reading of papers, the new society will pro- v e a much needed medium through which the members of the co mining profession in Cape Breton can voice their views o matters affecting the mining profession, such as, for ex- a le, the necessity for more generous expenditure on techni- ca education.

U ted States Coal in Competition with Canadian Coal.

he recent action of the Dominion Government in tempor- a y remitting the import duty of United States coal passing in the western provinces, although doubtless dictated by ne- c sity, and, from the viewpoint of the Government, quite d ensible, cannot be viewed with equanimity by any person i erested in the Canadian coal industry. The following ex- t ct, taken from the "Coal Trade Journal," of New York, is e of 16th August, merits the careful consideration of coal o rators and miners both in the West and in the East. Com- m ting generally on United States coal exports, the writer in t "Coal Trade Journal" states:

"Larger shipments will be made to Canada in future years a that country is growing, not alone in population, but com- r cially and industrially, and the greater the growth, the l ger the shipments of American coal will be, as there are p ces in the Dominion in which the home product cannot be l d down as cheaply as coal from the United States. Canada i ports almost as much coal from this country as is produced l all Canadian operators combined during a year, and when t re is trouble between miners and operators in the Domin- i the American producers gain. This is indicated by the d lers placed for coal in the United States as a result of the s rtage in western Canada caused by the strike of miners in t t territory, and it must be remembered how the Nova Scotian s ike helped the American producers to some extent, while t t was in force."

The operators in Nova Scotia have a very distinct recol- t tion of how the strike there helped the American pro- d cer, and it is more than probable that the Alberta operators w ll have a similar recollection when they look back some few y ars hence.

Canada takes 72 per cent. of the entire bituminous coal ex- rt of the United States. For the year ending 30th June, 11, Canada imported from the United States 8,627,963 tons soft coal, an increase of 1,359,205 tons, or 18.7 per cent. re than in the 12 months ending 30th June, 1910. Con- r sely, the United States imported from Canada 1,452,146 tons, m pared with 1,356,840 tons in the previous year, showing an c ease of 95,306 tons, which is a very insignificant quantity m pared with the enormous increase of exports from the n ited States to the Dominion. Averaged over the past de- d e, the yearly increase of Canadian coal production has not e ceeded half a million tons, whereas the coal output of the n ited States has gone up five million tons per annum.

The net result of the United Mine Workers strikes in Al- e ta and in Nova Scotia has been to displace millions of tons f Canadian coal by United States product, and coming events w ll prove to both the Canadian operator and the Canadian m ner how much easier it is to invite the invader than to re- c ver the trade he has taken from us. It is a grim commentary o this situation that the Government should have considered it n cessary to remove the import duties, and that the proper t rritory of Canadian coal mines should now be supplied by U ited States coal which is yielding no income to the Canadian revenues. In the St. Lawrence market the effect of the 1909 strike is still being felt by the Nova Scotian mines, and it is not probable that all the ground which has been lost will ever be recovered. Very recently a United States coal company took a large contract from the city of Montreal at a price which the Nova Scotian mines could not touch, and this is only a typical instance of what is occurring every day. Surely the folly of allowing Canadian labour relations to be endangered by strike mandates issued from Indianapolis could scarcely be more strikingly demonstrated.

Nova Scotia: Glace Bay.

The outputs for the first half of August were lessened by a general holiday on the occasion of the Provincial Workmen's Association's annual excursion, but there is a possibility that the record figure obtained in July may be slightly exceeded in August.

Extensive diamond drilling operations are being undertaken by the Dominion Coal Company at the Springhill mines, with a view to finding a suitable field for new winnings. The output is still steadily increasing.

With the accretion of the Springhill men, the membership of fthe Dominion Coal Company Employees' Benefit Society now amounts to 9,150 members, and the gross accumulated funds of the Society are now over $100,000.

The Dominion Iron & Steel Company have acquired extensive limestone deposits at Port au Port, Newfoundland, which they are at once commencing to develop. Work is now in progress on the loading arrangements and plant. The additional blast furnaces which the Steel Company are intending to install will require larger supplies of fluxing material than the present quarries will supply in the shipping season, and in addition to the Port au Port development the Steel Company have this year commenced another quarry at Ball's Creek, in the George's River limestone near Sydney.

NOVA SCOTIA.

Halifax.—The news of the shutting down of the Torbrook iron mines, owned and operated by the Canada Iron Corporation, Limited, reached Halifax some days ago. The closing of these important mines, it is hoped, is temporary. The Torbrook and Nictaux iron ore deposits are situated in the eastern part of Annapolis country. The workings are connected by a spur with the Dominion Atlantic Railway. When the Londonderry blast furnace was working, a considerable tonnage of ore was shipped there. Latterly some thousands of tons have been mined and shipped abroad.

The ores include hard red hematite, slightly high in phosphorus, and dark grey, low grade magnetites that carry varying percentages of lime. The latter are ideal ores for magnetic treatment.

As early as 1825, a small Catalan forge was operated in the Nictaux region for a short time. A charcoal furnace was also run for a short time. Many unsuccessfufl attempts were made to establish an iron industry. It was not until 1891, however, that serious mining was undertaken. In that year, Major R. G. Leckie, who was at that time general manager of the Londonderry Iron Company, acquired a large extent of territory and opened what is still known as the Leckie mine. The Leckie mine, which produced a high grade red hematite, was active until 1906. In 1903, it was again opened by the Londonderry Iron and Mining Company, an organization controlled by the Drummonds, of Montreal, and later merged in the Canada Iron Corporation.

Since 1906 the Leckie and the other mines have been worked irregularly. The otal output has been about 500,000 tons.

The failure of the Nova Scotian Government to send an exhibit of minerals to the Toronto Exhibition is much to be regretted. Nova Scotia can make a display that brings water to the mouth of the investor. As reports from Toronto state that many foreign mining men are passing through Toronto, it is a great pity that Nova Scotia's mines are not to be ad-

ed. Your correspondent is of the opinion that both the g Society and the Government are to blame. Nova will certainly have to do more advertising, or else be ut in the cold.

coal mines of the province are doing better than ever. This season's St. Lawrance trade promises to exceed last season.

Progress is being made at Dr. Cain's manganese property, nor of New Ross, Luuenburg County. It is reported that shipments will be made very soon.

Prospecting for tungsten ores is very active. Several old gold properties are being re-opened. It is rumoured that the old Dufferin is soon to spring a surprise on the public by showing signs of life. The Dufferin mine had a square deal. It should prove attractive.

ONTARIO.

Porcupine.—Every day brings its quota of new population. The whole camp is flourishing. The talk of the day is the auctioning off of lots at the Timmins townsite. High prices are expected. What effect this movement will have upon South Porcupine and Goldenville remains to be seen.

Nearly 500 men are at work at the Dome and more will be employed as soon as they can be obtained. The branch railway across the Dome Extension to the Dome is practically completed. The Dome siding will accommodate scores of cars.

Rebuilding is proceeding with remarkable vigour. Before the end of the current year the plants on the Foley-O'Brien, Dome, Dome Extension, West Dome, Apex, Dome (major), and on many other properties will have been restored completely.

Two hundred carloads of lumber are on their way to Porcupine. This implies a large amount of building. It must be remembered that many of the new buildings are to be of fireproof construction. Hence the railway traffic will be very far from now on.

Southeast Shaw is looking up well. There is room for the belief that this will make good.

At the Preston East Dome Manager Thorne is employing about 60 men. When the Dome siding has been completed necessary machinery will be rushed in.

The Hollinger office building is almost completed. Here, also, progress depends largely upon railroad construction.

A 10-stamp mill has been ordered for the Vipond. Mr. Pourrier has returned, and the mine is bustling.

C. Cleveland, a Nevada man, is to assume the management of the West Dome. Concrete buildings will be erected. Everything is now ready to commence reconstruction.

BRITISH COLUMBIA.

Hot weather experienced in July in the Cariboo district shortened the hydraulicking season for placer gold mines in the vicinity of Barkerville. Water in insufficient for continuing operations, so the season is practically over, unless copious rains shall come to give a fresh supply for gravel-washing. Very little news will be obtainable concerning operations on creeks in Atlin camp until after the close of the year's work and operators shall come south for the winter. Placer gold mining is being carried on in Fort Steele mining division, East Kootenay; there is activity on Perry Creek, and Wild Horse Creek is still receiving some attention as well. Placer mining returns for last year showed that gold to the value of $15,000 was recovered in the Omineca country, while Liboet was credited with a production of only $7,000—the smallest output for that district on official record. It is probable the total value of the placer gold production in 1911 will be higher than that of 1910. Totals in recent years were: In 18[illegible], $647,000; 1899, $477,000! in 1910, $540,000.

East Kootenay. 6

Coal mining has been at a standstill five months. As the combined output of Crow's Nest Pass coal mines last year was 1,365,000 long tons of coal, or an average of nearly 114,000 tons per month, the loss of production this year is already a serious one. After deduction of the proportion of coal made into coke, calculating with last year's average figures as a basis, the loss this year is already approximately 430,000 tons, net, of coal and 90,000 tons of coke, which represents a decrease in value of average production this year as compared with last of nearly $2,000,000. Further, even should there not be longer suspension of production than the five months abovementioned (and there probably will be) it will take several weeks to get the mines into full working condition again, so that a considerable margin will have to be allowed as an additional decrease in value of coal and coke produced this year. Then there is the contingency of a probable loss of market to also take into account, so the year's statistics of production may be expected to compare unfavourably with those of 1910.

Slocan.

Prospects for this district continue to improve, that is for the district as a whole. In the eastern part of Slocan, the construction of a spur from Three Forks, on the Canadian Pacific Railway from Slocan Lake to Sandon, to near Bear Lake, is in progress. This new line will give excellent transportation facilities to the Lucky Jim and Rambler-Cariboo mines, both of which have been at much disadvantage, in regard to shipment of ore, ever since the destruction in July, 1910, of bridges and trestles along several miles of the Kaslo & Slocan railway. As development work has been continued in both mines, and much ore has thereby been rendered available for shipment, production will be comparatively large whenever arrangements for freighting shall be favourable. The intended immediate resumption of work at the Deep mine of the Whitewater group, has been announced. Of these three mines, Mr. O. E. LeRoy wrote in his official report for 1910 (see "Summary Report" of Geological Survey, 1910): Whitewater.—The Whitewater includes the Deep property, as both are on the same vein, and are operated under one management. The destruction of the mill and village by fire in July caused a temporary cessation of mining operations. During 1909 a crosscut tunnel was driven to the vein from the valley of Kaslo Creek, which gives a vertical depth of about 1,400 feet below the apex of the vein, and about 400 feet below the Deep or lowest drift tunnel. The raise to connect with the present workings will be completed this winter, and at the same time intermediate levels and cross-cuts will be driven to prospect the vein between the main cross-cut and Deep tunnels. This is the most important development work recently undertaken in the Slocan district, and the results obtained will have a marked influence on further developments of similar character elsewhere in the district. Lucky Jim. This mine is the only one in the district worked almost exclusively for zinc. During the year 1909 about 4,700 tons were shipped, with zinc content ranging from 39 to 54 per cent. In 1910 No. 5 tunnel has been driven 200 feet vertically below the old workings, and has encountered two orebodies, the size and character of which has not yet been definitely ascertained. No. 6 crosscut is now being driven some 400 feet vertically below No. 5. The work this season was greatly hampered by the fire which destroyed all the buildings. Rambler-Cariboo.—Mining was seriously interrupted by the fire which destroyed the mine buildings in July, and the mine was only put on a working basis again in the early part of November. The orebody discovered in 1909 has been partially developed to the 8th and 9th levels, with very encouraging results. The shoot pitches to the south, and all the lower levels will be driven in that direction during the winter and the ground thoroughly explored. The development work is sufficiently advanced to permit immediate

and extensive stoping. The clean lead ore contains up to 64 per cent. lead and 175 oz. silver per ton.'' Quite recent advices are to the effect that shoots of ore of shipping grade have been opened on both the 1050 and 1250-foot levels of the Rambler-Cariboo mine, and that the 1400-foot level is being advanced with the object of cutting the oreshoots at the lowest level in the mine.

About Sandon, an amalgamation of the Slocan Star group with the Star M. and M. Company's claims, over which there had been litigation during eight or nine years up to the close of 1909, has been carried out, so that hereafter there should not exist any bar to the more ecenomical and thorough mining of fore-bodies occurring in both properties. Both the Richmond-Eureka and Ruth-Hope mines continue productive. Up Cody Creek, progress is being made towards again obtaining an appreciably large production of silver-lead ore from the Noble Five, Reco, Surprise, and Sunset mines.

Mines tributary to Slocan Lake give promise of making a larger total output this year than during any year for a long time. The more important producers are the Standard, Van-Roi, and Hewitt-Lorna Doone, each with much ore available and its own concentrating mill to make it marketable. Lower down the lake, the Ellis Silver Mining Company's Eastmont mine, and the Enterprise, both in Ten-mile Creek camp, are the more prominent properties. There are others, in Slocan City division as well as in other parts of the extensive Slocan district, that will also add to this year's total output of ore.

Nelson.

Gold is now produced to a greater value than any other metal in this mining division, and most of that comes from mines in Sheep Creek camp, where the Queen (in largest proportion) and the Nugget are steadily maintaining an output. The Granite-Poorman, situated within a few miles of the city of Nelson, is also a regular producer, having a valueble group of gold-baaring claims and a 20-stamp mill. Silver, lead, and copper ores also occur in this division, and in past years these metals have been produced to a comparatively large aggregate value, but at the present time they do not add much to the district's total value of mineral production. It is stated that several mines near Nelson, which have been asquired by a syndicate, are to be worked again, but so far little actual mining is being done on them. As some of them have been large producers in past years, it is hiped they will ere long be again on a profit-earning basis. Meanwhile, though, the best results are expected from Sheep Creek properties, where the Mother Lode, Kootenay Belle, Summit, and others have been proved to possess orebodies that it is believed will yield gold in payable quantity.

Rossland.

There is little information concerning this camp other than the customary report of continued production from the Consolidated Company's Centre Star group, the mines of the Le Roi No. 2, Ltd., and, in smaller degree, the Le Roi. Now that the last-mentioned mine has been acquired by the Consolidated Company, it is likely more ore will be mined in it and sent to Trail, since under the altered conditions it will probably be found profitable to utilize ore that previously could not be mined and smelted at a profit. There is not much to tell of the South Belt properties, of which the Blue Bird is now the most important, for it is almost alone in its continued aetivity.

Boundary.

The closing of the Granby Company's mines and dsmeltery, owing to the practical impossibility of securing a suitable supply of coke at moderate cost, has given part of this district a set-back for the time being. The cessation of work at the Snowshoe mine, by the Consolidated Company, has added to difficulties of the situation in Phoenix camp. Ae the time of writing the British Columbia Copper Company is operating its mines and smeltery, though under conditions that are n ordinarily profitable, the greater cost of Pennsylvania cok being a serious matter where, as in the case of Boundary di copper ores, the margin of profit is small when the pri copper is low, as at present. This company is developin McKinley mine, in Franklin camp, north fork of Kettle under an option of purchase. The Greenwood-Phoenix way Company is still driving its big tunnel, which is well on towards 3,000 feet. Railway construction up the fork of Kettle River is encouraging owners of mining perties about Beaverdell and other parts of the distri consider the practicability of turning to profitable ac some of the ores known to occur there.

Similkameen.

Coal mining is reported to be active around Princeton. erection of works for the manufacture of cement in the ity of that town is in progress. The completion of the way from Princeton to Coalmont, and the opening of a property in the neighbourhood of the latter place, are in Both placer and lode properties in Tulameen district are examined by prospective purchasers, while work is being ranged for to further test the river gravels of the Tula and some of its tributary creeks for both gold and platinu which latter metal an estimate of production in all yea date gives a total of about 20,000 oz.

Nicola Valley.

The Nicola Valley Coal and Coke Company is adding la to the coal-handling plant at its Middlesboro colliery and also made provision for much new exploration and dev ment work underground. Two or three other properties being got into shape for producing coal, of which there is mated to be about 30,000,000 tons in 12 square miles of bearing country in the valley.

Coast.

Coal mining is by far the most important branch of mining industry of the Coast district. Last year Vanco Island coal mines produced 1,616,030 long tons of coal; year, so far as known to the writer, all the mines are tinuing production, so that there is no good reason to su the current year's total output will be smaller. The se producers are: The Canadian Collieries (Dunsmuir) ,Lim with mines in both Extension and Cumberland districts; Western Fuel Company, with several mines near Nanaimo Pacific Coast Coal Mines, Ltd., with mines near Nanaimo at Suquash; and the Vancouver-Nanaimo Coal Mining pany, operating in the vicinity of Nanaimo. Prospecting coal is being done in various other parts of Vancouver Is and in some of the smaller islands lying east of it.

The Tyee Copper Company is receiving ores for redu at its smeltery at Ladysmith, Vancouver Island, from a ber of mines in the Coast district, and others in sou Yukon and Alaska. Two mines in Portland Canal distric among the shippers to its works, these being the Por Canal Mining Company's gold-silver-lead mine and the Cliff copper mine. Much development work has been do both mines, and both now have railway connection with wart, at the head of Portland canal. Prospecting on Portland Canal district claims is reported to be, in severa stances, satisfactory. At the Hidden Creek mine, Observe Inlet, which is an arm of Portland Canal, the Granby pany is doing much work, both underground and in su improvements. The directors have appropriated $200,000 this work, which is being carried out energetically an far as underground development is concerned, it is gene understood, with excellent results, much ore of good grade ing been found. In various parts of the Skeena district development of both coal and metal bearing claims is pushed on, while Queen Charlotte Islands are also rece attentiol both on coal and metalliferous properties.

GENERAL MINING NEWS.

NOVA SCOTIA.

Halifax.—Reports from Scheelite, Moose River, Halifax Co., show that the incline shaft at the tungsten mine has now reached an extension of 400 feet. A considerable amount of crosscutting and drifting has been accomplished. The 50-ton mill will soon be completed. The mill will consist principally of two sets of rolls, trommels, and Deister and Wilfley tables. W. Victor Hills, late of Denver, is in charge of the technical management, whilst Mr. H. C. Borden, of Halifax, directs financial affairs. No ore will be shipped until the mill is running.

ONTARIO.

Elk Lake, Ont., August 25.—Men going in from Gowganda to the Hudson Bay mine at Hanging Stone Lake, yesterday, were set upon by strikers. They turned back to Gowganda and asked aid of the provincial police.

The provincial constable at Gowganda refused to assist them, and application was made to District Chief Calbeck at Cobalt for adequate police protection. Failing this, a force of militia will be asked for.

There is a Socialist speaker at Elk Lake and Gowganda, inflaming the members of the Union with incendiary speeches.

Porcupine, Ontario, Aug. 14.—The McAulay-Brydge claims in Bristol township have been sold to Mr. B. E. Cartwright, of the Temiskaming mine at Cobalt, and the Pearl Lake mine at Porcupine, and associates for $5,000,000. The deal was completed when the decision of Mining Commissioner Price was given in favor of the owners respecting the recent law suit that was filed against the claims.

Cobalt, Aug. 16.—Mr. Sam Cohen, who has just returned from a visit to the McEaneny property at Porcupine, reports developments on this holding of the Crown Reserve. Recent trenching has opened up a 12-foot vein of quartz and schist carrying free gold and paning well. The McEaneny property adjoins the Hollinger, and from the strike of this vein and that on the main lead on the Hollinger, it is believed that further development will reveal that it is an extension of the big vein. A shaft has been put down fifty feet and some drifting done on another lead with promising results. Fifty men are employed and a small plant is furnishing power.

Sudbury.—At Long Lake, the Canadian Exploration Company is pushing on development work with highly satisfactory results. The addition to the mill of ten stamps with enlarged cyaniding plant, ensures an increased output of the precious metal.

Cobalt.—Eleven bars of bullion were sent out by the Crown Reserve mine August 24, to Montreal, and will be shipped to Mocatta & Goldsmith, London, Eng., who have purchased the greater portion of bullion shipped from Cobalt. The consignment contained 14,773 ounces of silver and was valued at $8,000. This is the first bullion from the Crown Reserve during August.

BRITISH COLUMBIA.

Fernie, Aug. 14.—The ending of the balloting and the announcement of the results throughout the mining district last Saturday marked the end of the excitement over that affair and the town of Fernie has settled down to a quietness which is noticeable to all. Not a ripple of excitement of any kind disturbs the surface of current events; there is no current.

The Corbin mine is still working and has turned out 45 cars of coal in the two weeks operations have been carried on. This coal all goes to the American side, and is cleared through United States Consul Denison's office here.

Absolutely nothing is known of any new move being made by either side to the dispute and it looks as though the Dominion election made matters too delicate for harsh measures to be adopted.

Kaslo.—The Deep Mine, Ltd., will resume operations at once with a crew of 30 men, who will continue at work all winter. The narrow gauge road will be put in order and several cars of lumber will be hauled up for the purpose of rebuilding the structures destroyed by fire last year. This will also enable the Utica mine to ship several hundred sacks of ore, the result of last winter's mining, and will also be a great assistance to those who wish to develop properties in this promising district.

Nelson.—The mill at the Molly Gibson mine is now in steady operation, and about 300 tons of ore are being run through every week. Development of the property is being continued in addition to the getting out of ore for the mill.

Victoria.—The next general meeting of the western branch of the Canadian Mining Institute will be held at New Denver, Slocan Lake. The date has not been definitely determined, but it will be during either the second or third week in September. It is intended to give especial attention to the reading and discussion of papers on subjects connected with mining in Slocan district.

Vancouver, August 19.—Forty-eight thousand acres of bituminous coal lands on Copper River, a tributary of the Skeena in northern British Columbia, have been acquired by a syndicate of London financiers from the Vancouver owners. It is proposed to organize a company and proceed with development work on an extensive scale. The programme already adopted provides for the expenditure of at least $600,000 in development work and equipment during the next twelve months. The deal was negotiated by Mr. R. H. Frisby, who returned to Vancouver a few days ago, after a ten months' stay in London and Paris. Mr. Frisby, accompanied by two engineering experts, has left for Prince Rupert en route to the property, where a small force of men have been engaged at development work since early last spring.

MINING NEWS OF THE WORLD.

OUR EUROPEAN LETTER.

British mining markets still dull—International Miners' Convention passes many resolutions—Colliery results good—His Majesty's Chief Inspector of Mines writes on mining ventilation—New machinery in Cornwall—Rand outputs and profits—Scottish and German oil developments.

Exclusive Correspondence of the "Canadian Mining Journal."

London, August 18th, 1911.

The condition of the mining markets here is still not good and general dulness and apathy rule. Of course, the abnormally good summer weather has a great deal to do with this. With the coming of such a rare heat wave as we have just been experiencing in this country brokers, dealers, and investors all flock away from town into the country or down to the shore, and markets become silent wastes. Apart from this, however, there have been many other distinctly adverse factors and curiously enough these factors are equally unconnected with the intrinsic values on the market itself. For example, political, financial, and labour troubles have been very strong. At the time of writing the country is in the throes of the great-

est labour upheaval it has ever known and people's thoughts are more likely to be fixed on questions of transport and food supplies than upon stocks or shares—anyhow for the time being. Considering the many irritating factors at work it is surprising that the mining and oil share values are not lower than they are and that they can so well resist such malign influences is some proof of their general level of sound value.

In the last week of July the International Miners' Congress was held in Lindon, miner labour delegates attending from Germany, Austria, France, Belgium, Holland Sweden, and Bulgaria, as well as, of course, from Great Britain. Resolutions were carried advocating the nationalization of all mines and their exploitation by the State for the national benefit. Under French law all minerals are the property of the State, and resolutions demanded that no further mining concessions should ever be granted to private individuals. This was an echo of the resolutions passed at mining labour conventions in France, Germany, and Austria recently.

Another resolution demanded that inspectors of mines in Europe should be men of practical experience who should be elected by the miners from among their own ranks and paid by the State. A minimum wage for coal miners was also demanded. This, it was said, is supposed to prevail in Great Britain, and in connection with this discussion it transpired that there had been an enormous increase in the number of men employed in the British mining industry. In 1868 the number employed was 346,820, whilst now it well exceeds one million, an increase of about 300 per cent. The thing that interferes apparently with the mininmum wage in this country is the ever-present question of payment for abnormal working places. German and Belgian delegates demanded that the employment of children under 14 years of age in mines should be entirely prohibited, and that no one under 16 should be permitted to work underground. Belgian delegates were in favour of the limitation of the production of coal. This question is one which has been before the Miners' International Congress for many years, but the difficulties in the way of a working agreement covering all the countries of Europe have so far proved insurmountable.

The reports of a number of British collieries which make up their accounts to the end of the calendar year have come to hand recently, and as the group, though not large, is a representative one, the returns given a good idea as to how the industry fared in 1910, as compared with 1909. As might be expected, the record on the whole is a good one, for it has to be remembered that the comparison is with a particularly difficult period when not only were the average prices of coal low, but the cost of production was increased, owing to the friction between masters and men over the readjustment of hours and wages consequent upon the coming into force of the Miners' Eight Hours Act. The latter factor was still operative last year to the extent of the increase in wages per ton of coal raised, which resulted from the readjustments referred to, but, with the exception of the unfortunate dispute at the Cambrian Collieries, there were few serious stoppages. Prices during the first half of the year, moreover, steadily improved, and though there was some reaction in the autumn, the average figures realized were decidedly better. The Welsh companies have, undoubtedly, suffered more from the Eight Hours Act than the collieries in the north of England, and in Scotland, the restriction in output under the new arrangements being greater, while interruptions of work were more frequent, but the good demand for bunker coal, consoquent upon the revival in the shipping trade, has helped the companies, even in this section, to make a very good showing. In other districts the results were still more satisfactory. In the aggregate, the advance in profits is equal to about 50 per cent., which more than wipes out the decline of 36 per cent. which occurred in 1909, and while the individual returns vary considerably, in only one instance is there any falling off in profits.

A most interesting series of mining publications under title of "Modern Practice in Mining," is being issued in t country. Volume IV., which is just issued, deals with ventilation of mines and is from the pen of R. A. S. Redmay who is His Majesty's Chief Inspector of Mines. Mr. R mayne's position adds considerably to the importance of t work, although the natural importance of the subject is c siderable at any time. Just at present even more than us attention is being given to it, as a result of recent seri colliery explosions and the keen interest now veing evin in the problems of coal dust and firedamp explosions, which in some degree related to the problem of ventilation. The r of explosion is, however, not the only thing to be kept in mi and Mr. Redmayne wisely devotes a good deal of space t consideration of the chemical and physiological properties mine gases.

In this country particularly the increasing depth and area mine workings is adding greatly to the difficulties of venti tion, for not only is the mechanical problem of supplying greater than formerly, but the difficulties of supplying a sa factory quality of air are increasing even more rapidly. Te peratures up to 94 degrees Fahrenheit have been recorded the working face of the Pendleton Colliery, and as high as degrees at some of the Belgian collieries. Unfortuuately t air below ground is usually, although not always, exceedin humid, so that the physical labour of mining at great dep is very exhausting. Mr. Redmayne hints at the urgency of new ventilation problem in his introduction, but it is greatly be regretted that he does not attempt any critical study of t aspect of the question. He suggests auxiliary fans and frigerated air, and the indications are that ultimately a care control of temperature, humidity, and composition will necessary in the deeper and more extensive mines.

Mr. Redmayne does not specifically refer to colliery warni issued at times of low barometer, but he discusses the effect a fall in the barometer generally, and points out that the fo ing of the mine air which accompanies such a change usua results from the expansion of the foul gases in the wastes of t mine or goaf, and not from an eruption of fresh firedamp, si the discharge pressure of this last is usually far too high be effected by a small change in the atmospheric pressure. Redmayne also refers to the curious fact, several times not by different people, that the fouling of the mine gases f quently precedes the fall in the barometer by a brief interv

The author is at his best when describing mining pract or experimental facts. When he comes to discuss scienti principles, or theory, he is much less satisfactory. Mining gineers seldom approach their engineering problems in a ve sound and logical way, but prefer empiricism and an avo ance of scientific argument. The chapter in this book devot to fans and the calculation of air currents are in some pa quite crude, and as a whole are defective in logical treatme One other complaint must be entered. Less than eleven pag are devoted to colliery explosions and "gob fires." It is arg able, of course, that a discussion of colliery explosions is o side the scope of a book on ventilation, but if it is tackled at its importance demands a more complete and a more up- date discussion than Mr. Redmayne has accorded it.

An interesting roasting plant is being supplied to a prom ent tin mine in Cornwall. The plant consists chiefly of t Humboldt mechanical roasting furnaces, patented of the la est type. These patented furnaces are in this case used f roasting down pyritical concentrates carrying tin oxide. Th represent the latest development in the multiple hearth type roasters, both as to capacity and adaptability to various grees of calcining, and are an innovation for Cornwall, whe they will not doubt perform the same satisfactory service they are doing at other mines recently furnished with san in the Pyrenees and elsewhere.

tops of the furnaces serve for a preliminary drying of re, which is then fed mechanically on to the uppermost a of the furnace, travelling down gradually to the lower hs, and meeting on its way the fire gases which are moving the opposite direction on the counter current principle. A tical ring shaft extends through the centre of the furnace carrying easily exchangeable arms with stirring rabbles to move the material along on each of the five hearths. The oasting can easily be changed through all stages from a "sv et" to a "dead" roast. The normal capacity exceeds 10 tons per day when roasting down the ore from 30 to about 3 per nt. of sulphur. The furnaces are entirely self contained, and require very little foundation. All wearing parts eas east renewable. There is every reason to believe that their use will prove of material benefit to the mine. Their introduction in a larger sense appears to mark another decided advance above certain obsolete mining practice, by modern ore dressing science such as is consistent with safety and reliability.

The creation of a new record in the Witwatersrand gold output has not been accompanied by a corresponding expansion in profits. The net earnings of the controlled mines in July amounted to $4,900,000, as compared with $4,880,000 in June, a total which has not been exceeded during the past two years. But seeing that the yield from these mines was advanced by over $400,000, and moreover, that a newcomer — the Brakpan — is responsible for nearly $65,000 of profit, the expansion of $20,000 in the total is not altogether satisfactory. Broadly speaking, the failure of profits to keep pace with the increase in output arises from efforts to combat a "temporary falling off in the grade of the stopes in some mines by increasing the tonnage, and as this was not always accompanied by any appreciable saving in costs, the expansion in profits obviously could not be large. In some cases, indeed, growth in quantity failed to compensate for reduction in value. For example, the Geduld Deep endeavored to offset a drop in grade in the Geduld Estate and Jumpers Deep sections by increasing the tonnage from 67,300 to nearly 69,000. But costs were above the normal — possibly in consequence of extra expense due to the caving in of the No. 1 shaft — and the profit came out $10,000 lower at $110,000. A somewhat similar instance is supplied by the Crown mine. This company treated 143,000 tons, as against 141,000 tons, yet the mining profit of $549,750 is only $2,250 in excess of the June total.

Believers in oil and its future, and they are many, are disregarding the apathetic position of the public towards oil shares at the present time. They are looking more towards the increasing evidence of the expanding use of oil. This country's oil deposits are found in Scotland, and it is rumoured, on what appears to be good authority, that an offer has been made on behalf of certain powerful interests to acquire the properties owned by the four oil-producing companies operating in Scotland. The price mentioned is $15,000,000, and this figure, if correct, appears to be sufficiently tempting to cause the directors to think very carefully before rejecting the proposal. There is a good deal of unrest just now oming the shareholders of these Scottish oil companies, owing to the severe competition with which they are faced, and a meeting was held recently at which representatives of the various undertakings attended in the hope of agreeing upon some definite line of action which would be acceptable to all concerned. A committee was formed, and there the matter rests for the present. As regards the source of the reported offer to buy up the principal oil-producing properties in Scotland, America, would, of course, "be the most likely "port of origin" for such a proposal.

It is persistently rumoured that the German Government is contemplating far-reaching measures for the protection of the petroleum industry. The National Liberals have been urging the necessity of counterecting the policy of the Standard Oil Company and its offshoots. A resolution calling for inquiry was adopted by the Reichstag, although the Government did not define its attitude. It was stated here recently that the Government is actually preparing a Petroleum Monopoly Bill for presentation to the Reichstag next year. The accuracy of this statement has been semi-officially denied, but in a form which suggests rather that no definite decision has been reached than that the reports are without foundation.

COMPANY NOTES

INTERCOLONIAL COAL.

Intercolonial Coal preferred declared a dividend of 3½ per cent, payable September 1 to shareholders of record 18th inst. Books will close from August 18 to September 1, inclusive.

KERR LAKE DIVIDEND.

Kerr Lake directors have declared the regular quarterly dividend of 25c. per share and 15 cents per share extra, payable September 15, to holders of record September 15.

CROWN RESERVE DIVIDEND.

Crown Reserve declared a dividend of 2 per cent., with a bonus of 3 per cent., payable on 15th September of record 31st August. Books will not be closed.

GRANBY FOR YEAR.

The net income for Granby Consolidated for the fiscal year ended June 30th was approximately $282,000, assuming a copper cost of 10¾ per pound and selling price of 12.33. Production was 17,795,215 pounds of copper, the smallest since 1906, when slightly over 16,000,000 pounds were produced.

NIPISSING HALF-YEAR.

The financial statement of the Nipissing Mines Company for the half year to July 1, was recently published and in itself gave no clue to the causes for the decline in the stock, the mine being stronger in cash assets at the end of June than it was at the same time last year. The output, however, showed a considerable falling off, and the figures of output for the first half of the year show that production fell below dividend requirements a little, owing to the power shortage early in the year. The output for June, however, was the biggest of the yeaf, so the company is picking up again.

The shipments by months, with the estimated value, were:

	Shipments Ounces.	Net value at at the mine.
January	331,038	$158,046
February	194,185	95,121
March	332,352	168,338
April	406,933	207,679
May	444,053	219,324
June	535,148	262,945
	2,243,709	$1,111,453

Last year, according to the annual report, the cost of producing silver was 14.72 cents per ounce. Taking the same cost this year, and assuming the average price of silver to be 53 cents per ounce, a net profit of 38,28 cents per ounce is shown. On a production of 2,243,709 ounces for six months this shows a net profit of $858,891. Dividend requirements in this period call for $90,000.

THE McKINLEY DIVIDEND.

The McKinley-Darragh-Savage mines have declared the regular quarterly dividend of 3 per cent. and also a bonus dividend of 7 per cent. on the capital stock.

LE ROI No. 2.

The following cable has been sent to London: "Josie mine report for July: Shipped 2,350 tons of ore and 136 tons of concentrates. The receipts from smelter are $25,87 (£5,334)), being payment for 2,226 tons shipped, and $3,126 (£654), being payment for 136 tons concentrates shipped. In all, $28,999 (£5,979). Estimater cost for corresponding period: Development, $3,000; ore production, $10,000; milling, $1,300—$1[illegible] (£3,979). Hamilton west drift, 300 ft. level—Advance 7[illegible] ft. Holywell drift, 300 ft. level—Advance 120 ft. Poorman [illegible] ft. 500 ft. level—Advance 104 feet. The first 30 feet cr[illegible] cut east of fault; vein intersected. The first 20 feet alon[illegible] or averaged 1 oz. 11 dwts. gold and 1¼ per cent. copper [illegible] 11 inches."

COPPER EXPORTS SMALLER.

New York exports of copper for the week ended Augu[illegible] were 7,372 tons; since August 1st, 15,908 tons; same time [illegible] year, 17,748 tons.

STATISTICS AND RETURNS

COBALT ORE SHIPMENTS.

Following are the shipments from the Cobalt camp for the week ending August 25, and those from Jan. 1 1911, to date:

	Aug. 25. Ore in lbs.	Since Jan. 1. Ore in lbs.
Badger	.....	55,200
Bailey	.....	40,000
Barber	.....	6,000
Beaver	125,495	1,278,473
Buffalo	.....	1,800,254
Chambers-Ferland	.....	895,000
City of Cobalt	.....	557,980
Cobalt Lake	127,570	2,698,170
Cobalt Townsite	64,520	719,380
Colonial	.....	135,410
Coniagas	64,250	2,660,354
Crown Reserve	145,940	1,733,529
Drummond	110,000	290,000
Hargreaves	.....	161,100
Hudson Bay	60,000	941,990
Kerr Lake	60,795	1,805,585
King Edward	.....	40,000
La Rose	159,550	4,677,278
McKinley-Darragh	189,700	4,027,864
Nipissing	177,540	4,208,378
O'Brien	.....	938,358
O'Brien, M. J.,	.....	47,000
Peterson Lake, Little Nip	.....	58,430
Provincial	.....	101,670
Right of Way	60,570	830,115
Silver Cliff	.....	106,680
Standard	.....	102,813
Temiskaming	140,520	1,181,892
Trethewey	.....	834,420
Wettlaufer	.....	117,232

The shipments for the week were 1,486,450 pounds, or 743 tons.

The shipments from Jan. 1 to Aug. 25 were 32,539,191 pounds, or 16,269 tons.

In 1910 the shipments amounted to 34,420 tons.

COBALT ORE SHIPMENTS.

Folowing are the shipments from the Cobalt camp for the week ending Aug. 4, and those from Jan. 1, 1911, to date:

	Aug. 11. Ore in lbs.	Since Jan. 1. Ore in lbs.
Badger	.....	55,200
Bailey	.....	40,000
Barber	.....	6,000
Beaver	62,000	1,029,678
Buffalo	65,120	1,734,104
Chambers-Ferland	64,000	895,000
City of Cobalt	.....	557,980
Cobalt Lake	60,000	2,507,600
Cobalt Townsite	76,760	654,760
Colonial	47,410	135,410
Coniagas	120,390	2,533,34[illegible]
Crown Reserve	47,750	1,587,58[illegible]
Drummond	60,000	60,000
Hargraves	.....	161,10[illegible]
Hudson Bay	65,710	816,70[illegible]
Kerr Lake	61,020	1,684,05[illegible]
King Edward	.....	40,000
La Rose	127,800	4,114,16[illegible]
McKin.-Dar.-Sav.	53,290	3,718,57[illegible]
Nipissing	00,000	3,966,83[illegible]
O'Brien	.....	864,31[illegible]
O'Brien, M. J.,	.....	47,000
Peterson Lake, Little Nip.	.....	58,43[illegible]
Provincial	.....	101,67[illegible]
Right of Way	.....	708,99[illegible]
Silver Cliff	.....	106,68[illegible]
Standard	.....	102,81[illegible]
Temiskaming	.....	1,041,37[illegible]
Trethewey	.....	785,52[illegible]
Wettlaufer	.....	117,23[illegible]

The shipments for the week were 975,210 pounds, or 487 [illegible]
Teh shipments from Jan. 1 to Aug. 11 were 30,332,26[illegible] lbs.
The Boyd-Gordon also shipped 2,590 pounds last wee[illegible]

COBALT ORE SHIPMENTS.

Following are the shipments from the Cobalt camp fo[illegible] the week ending Aug. 19, and those from Jan. 1, 1911, to date:

	Aug. 19. Ore in lbs.	Since Jan. Ore in l[illegible]
Badger	.....	55,20[illegible]
Bailey	.....	40,00[illegible]
Barber	.....	6,00[illegible]
Beaver	123,300	1,152,97[illegible]
Buffalo	66,150	1800,25[illegible]
City of Cobalt	.....	557,98[illegible]
Chambers-Ferland	.....	895,00[illegible]
Hargraves	.....	161,10[illegible]

It makes no Difference

whether you mill, smelt or ship your ores you must have assays and analyses of unquestionable accuracy reported to you in the shortest possible time. Our equipment is especially designed to meet these requirements.

WE also test ores in a practical way to determine just what metallurgical process is best adapted to it to secure the highest commercial results. Write us for prices for your particular problem.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

DEPARTMENT OF MINES. GEOLOGICAL SURVEY

PUBLICATIONS

The Geological Survey has published maps and reports dealing with a large part of Canada, with many local areas and special subjects.

A catalogue of publications will be sent free to any applicant. A single copy of a map or report that is specially desired will be sent to a Canadian applicant free of cost and to others at a nominal price. The applicant should state definitely the precise area concerning which information is desired, and it is often of assistance in filling an order for a map or report if he states the use for which it is required.

Most of the older reports are out of print, but they may usually be found in public libraries, libraries of the Canadian Mining Institute, etc.

REPORTS RECENTLY ISSUED:

CANADA

1085. Descriptive Sketch of the Geology and Economic Minerals of Canada. Accompanied by a geological and mineral map of Canada, by G. A. Young and R. W. Brock.
1170. Summary Report of the Geological Survey for 1910.

NEW BRUNSWICK and NOVA SCOTIA

1113. Memoir No. 16. The Clay and Shale Deposits of Nova Scotia and portions of New Brunswick, by H. Ries and J. Keele.

QUEBEC

1110. Memoir No. 4. Geological reconnaissance along the line of the National Transcontinental Railway in Western Quebec, by W. J. Wilson, accompanied by a map.
1064. Geology of an area adjoining the east side of Lake Timiskaming, by Morley E. Wilson.

ONTARIO

1091. Memoir No. 1, Geology of the Nipigon Basin, Ontario, by A. W. G. Wilson.
1137. Memoir No. 10. An instrumental survey of the shore-lines of the extinct lakes Algonquin and Nipissing in South-western Ontario, by J. W. Goldthwaite.

NORTH WEST PROVINCES

1115. Memoir No. 8. The Edmonton Coal Field, Alberta, with maps, by D. B. Dowling.

BRITISH COLUMBIA

1139. Memoir 11-T Triangulation and Spirit Levelling of Vancouver Island, 1909, by R. H. Chapman.

YUKON and NORTH WEST TERRITORIES

1080. Report on a part of the North West Territories drained by the Winisk and Attawapiskat Rivers, by Wm. McInnes.
1006. Report on a traverse through the southern part of the North West Territories from Lac Seul to Cat Lake in 19, by A. W. G. Wilson.
1130. Memoir No. 9. Bighorn Coal Basin, Alberta, by G. S. Malloch, accompanied by a map.

MAPS RECENTLY ISSUED:

CANADA

1042. Mineral Map of Canada. Scale 100 miles to 1 inch.
1084. Geological Map of Canada. Scale 100 miles to 1 inch.

NOVA SCOTIA

1133. Map 13 A. Kingsport sheet, Nova Scotia, No. 84. Scale 1 mile to 1 inch.

NEW BRUNSWICK

1155. Map 24A. Millstream Iron Deposit, Gloucester County, N.B., geological and topographical. Scale 400 ft. to 1 inch.
1156. Map 25 A. Nipissiguit Iron Deposit, Gloucester County, N. B. Geology and topography, scale 400 feet to 1 inch.

QUEBEC

1066. Map 18 A, Lake Timiskaming Mining Region. Scale 1 mile to 1 inch.
1112. Map 12 A. Vicinity of the Transcontinental Railway, Abitibi District, Quebec. Scale 4 miles to 1 inch.
1154. Map 23 A. Thetford-Black Lake Mining District. Scale 1 mile to 1 inch.

ONTARIO

1091. Map 8 A, Lake Nipigon, Thunder Bay District, Ontario. Scale 4 miles to 1 inch.

ALBERTA

1132. Map No. 7A. Bighorn Coal Area, Alberta, by G. Malloch. Scale 2 miles to 1 in.

BRITISH COLUMBIA

1135. Map 15A. Phoenix, British Columbia, topographical. Scale 400 ft. to 1 inch.
1148. Map 20A. Victoria sheet, Vancouver Island, B.C., topographical. Scale 1 mile to 1 inch.
1149. Map 21A. Saanich sheet, Vancouver Island, B.C., topographical. Scale 1 mile to 1 inch.
1164. Map 28 A. Sketch map of Portland Canal Mining District.

YUKON and NORTH WEST TERRITORIES

1089. Map 9A. Explored Routes on Parts of the Albany, Severn and Winisk Rivers. Scale 8 miles to 1 inch.

NOTE.—Maps published within the last two years may be had, printed on linen for field use. A charge of 10 cents is made for maps on linen.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon. Letters and samples that are of a Departmental nature, addressed to the Director may be mailed O.H.M.S. free of postage.

Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.

BRITISH COLUMBIA

The Mineral Province of Western Canada

Has produced Minerals valued as follows: Placer Gold, $71,213,103; Lode Gold, $60,811,067; Silver, $31,095,602; Lead, $24,645,605; Copper, $60,743,405; Other Metals (Iron, Zinc, etc.), $1,083,172; Coal and Coke, $114,012,596: Building Stone, Brick, etc., $10,593,100; making its Mineral Production at the end of 1910 show an

Aggregate Value of $374,197,650.

In 1910 the quantity of Ore mined was 2,216,428 tons, and of coal 3,139,235 long tons. The value of Minerals produced that year was: Placer Gold, $540,000; Lode Gold, $5,533,386; Silver, $1,245,016; Lead, $1,386,350; Copper, $4,871,512; Coal and Coke, $11,108,335; Other Minerals, $1,692,473, making the

Total Value for 1910, $26,377,066.

Lode mining has only been in progress for about eighteen years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those in any other Province in the Dominion, or any Colony in the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with mining Reports and Maps, may be obtained gratis by addressing

When answering Advertisements please mention THE CANADIAN MINING JOURNAL

Province of Quebec

Department of Colonization, Mines, and Fisheries.

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdeni Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, Etc.

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

MINERS' CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. h price of this certificate is $10.00 and it is valid until the first of January following. This certificate gives the right to prospec public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed t extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his ri must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty C an acre per year and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affi that during the year work has been performed to the extent of at leas' twenty-five days labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $10 an acr SUPERIOR METALS when more than 20 miles distant from a railway and $20 an acre when less than 20 miles.

For INFERIOR METALS the prices are $2.00 and $4.00 an acre respectively.

The attention of prospectors is specially called to the territory in the North-Western part of the province of Quebec, north o height of land, where important mineralized belts are known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERS 228 ST. DENIS STREET, MONTREAL, for the determination, assays and analysis of minerals at very reduced rates for the bene miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists e results of undoubted integrity and reliability.

The Bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources o Province, on application addressed to

THE HONORABLE THE MINISTER OF COLONIZATION, MINES, AND FISHERIES, QUEB

Province of Nova Scotia

Leases for Mines of Gold, Silver Coal, Iron, Copper, Lead, Tin

AND

PRECIOUS STONES

Titles given Direct from the Crown, Royalties, and Rentals Mode

Copies of the Mining Law and any information can be had on application to

The Hon. Christopher Chisholm

Commissioner Public Works and Mines, - - HALIFAX, NOVA SCO

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

ANNOUNCEMENT

THE CANADIAN MININC JOURNAL'S

PORCUPINE SERIES

VOLUME I.

A SERIES OF UNIQUE ILLUSTRATED ARTICLES.

Accompanied by a Complete Geological Map and Claim Maps of the Various Townships

The Publishers of *The Canadian Mining Journal*, in view of the fact that the demand for back numbers containing articles on Porcupine cannot be met, are bringing out a book embodying descriptive, geological, and general data relating to Porcupine. The latest available township maps and a large Geological Map will be included. The object of the publishers is to present in compact form a book that will guide the investor, the engineer, and the general reader.

The book will be on sale within a few days.

The price is $2.00 per volume. For orders of more than ten volumes a reduction of ten per cent will be made. The edition is limited.

Canadian Mining Journal, 17-23 Manning Arcade Annex, Toronto

A MESSAGE

TO

MINE SUPERINTENDENTS

WHO HAVE

IDEAS OF THEIR OWN

We will build your Skips, Ore-cars, Sinking Buckets, etc., to your own drawings, and exactly as you want them, or we will submit drawings for your approval.

DON'T let anybody force **CHEAP STOCK CARS** on you, when you can get them built as you know they ought to be.

You will find our cars in every Mining Camp in the North.

We are also prepared to furnish Tube Mill Liners. Chilled Wheels and Castings of all descriptions.

THE

SUDBURY CONSTRUCTION & MACHINERY CO.

LIMITED

SUDBURY :: ONTARIO

ORE DRESSING

The School of Mining, Kingston, Ont., is prepared to make mill runs on **GOLD ORES** in lots of from 2 to 20 tons to determine average value, percentage of free milling gold and to recommend the best method of treatment,

Also **CONCENTRATION TESTS, ORE SAMPLING, and ASSAYING.**

Terms on application to

GEO. Y. CHOWN
Secretary of School of Mining
KINGSTON, ONT.

MINING AND SCIENTIFIC PRESS

Controlled by T. A. Rickard | **Established 1860** | **H. Foster Bain, Editor** | **Published weekly** | **Thomas T. Read, Associate Editor**

In every issue valuable articles are published on mining, metallurgy, and geology, the latest news from special correspondents at the principal mining centers, letters giving the ideas and experience of successful men, and other items of useful knowledge.

THE MINING MAGAZINE

Established September, 1909

T. A. RICKARD, Editor **Published monthly at London, England**

A monthly magazine is the natural corollary of a technical weekly. It permits of more deliberate and more extended notice of matters concerning which the news element is less important.

The Mining Magazine includes a review of the world's progress in mining, metallurgy, and economic geology, written by men who have personal knowledge of the regions and conditions discussed.

COMBINATION RATE: To new subscribers to both papers in	Combination yearly rate
Canada U. S. and Mexico,	$6.00
United Kingdom	7.00

VOL. 32 TORONTO No.

REMEMBER—

We do not confine ourselves to Machinery such as the renowned

Holman Steel Rock Drill, and Fraser and Chalmers

Engines, Compressors, Etc.

We also have a complete line of

SUPPLIES—

Such as Drill Steel, Fuse, Batteries, Wire Rope, Mine Cars, Wheelbarrows, Picks, Shovels, Mine Cages, Buckets, etc.

We carry all these in stock.

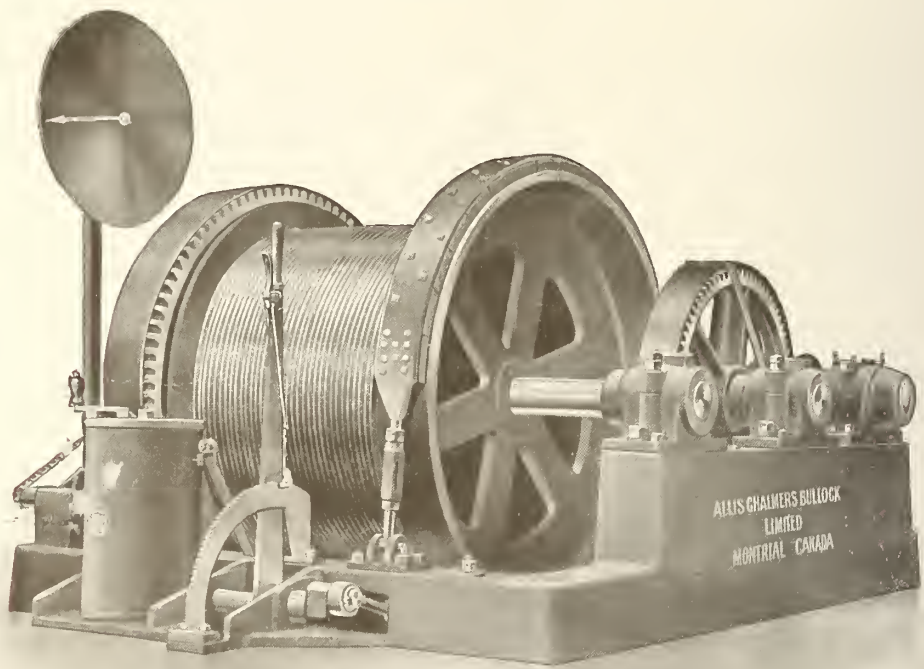
Electric Hoists
FOR
Mining Work



We design and build both electrical and mechanical parts of an electric hoist and are therefore able to guarantee satisfactory operation of the complete unit. The hoist in the illustration was designed for a lift of 5000 lbs. at the rate of 500 feet per minute.

General Office and Works:-Chicago Heights, Ill. **New York Office:-Singer Bldg.**

CHOOSE THE RIGHT DRILL

Sullivan 3 inch drill at a Wabana, Nfld, iron mine.

The cost and speed of your rock excavation depend much on the size and type of drill you select.

A machine too large for your work will make your power and labor bills too high. Too small a drill will be expensive for repairs. One valve motion is suited for high air pressure and hard rock, while low pressure or soft ground need another style. But be sure your drill is a "Sullivan." Whatever the size or style, it will drill faster and cost you less for power and repairs, than any equivalent drill.

We are experts in fitting of drills to working conditions.

Our advice is free. Do you want it?

Ask for Bulletins 666A 666B

Diamond Drills, Hammer Drills, Air Compressors, Coal Cutters, Hoists.

Amatite ROOFING

FOR MINE BUILDINGS

AMATITE is exactly suited to mining buildings because:

1—It can be laid by unskilled labor.

2—It has a real mineral surface *which requires no painting.*

3—Its cost is lower than that of other ready roofings of less weight.

4—It comes in rolls ready to be unrolled on the roof and nailed down.

5—The necessary nails and cement are supplied free, packed handily in the centre of each roll.

The mineral surface of Amatite is somewhat of a novelty: and the fact that it obviates the old painting nuisance, is giving to this roofing the leadership of the ready roofing industry.

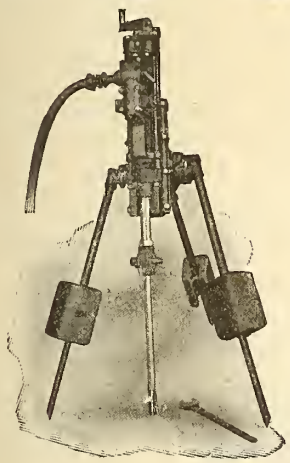
The surface consists of mineral particles embedded under great pressure into a tough plastic matrix of pitch.

A sample of Amatite will be sent free on request.

The Paterson Mfg. Co., Ltd., Montreal, Toronto Winnipeg, Vancouver, St. John, N B. Halifax, N. S.

"LITTLE GIANT"

ROCK DRILLS



A Rand "Little Giant" Rock Drill is more than a mere rock drilling machine, it is the embodiment of years of rock drill building experience, crystallized in the design of one machine.

This experience has necessitated the great many changes which have been made in the "Little Giant" construction and which have won for it the present position of superiority which it holds.

Such extensive experiments and changes have incurred great expense, but the result is a product of unusual endurance, efficiency, reliability and economy which can only be attained by long and unlimited experience.

CANADIAN RAND CO., LIMITED

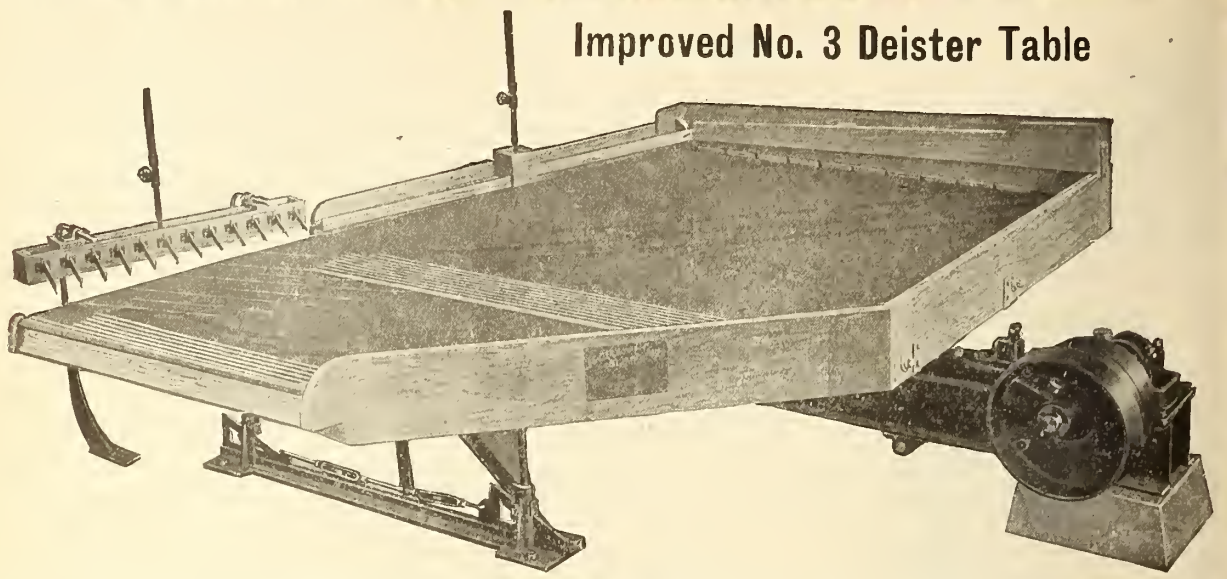
Improved No. 3 Deister Table



THE vanner has been a most efficient type of concentrating device for a decade. Competitive tests in such well-known mills as **Goldfield Cons. Mines Co., Goldfield, Nevada; Miami Copper Co., Miami, Arizona; Stratton's Independence, Ltd., Victor, Colorado; Old Dominion Copper Co., Globe, Arizona; Detroit Copper Co., Morenci, Arizona; and Ohio Copper Co., Lark, Utah;** have proven the Improved No. 3 Deister table superior in efficiency on feeds of 80 mesh and finer. A pleased customer remarks: "Your No. 3 Table does as good work for us as vanners at a tithe of the cost for repairs."

The Deister Concentrator Company, Ft. Wayne, Ind., U.S.A.

CLOSE REGULATION

The McEwen is regulated by the famous BEGTHRUP INERTIA GOVERNOR. With it the engine can be adjusted to govern within the limit of one revolution without difficulty. The instantaneous variation of speed when the entire load is thrown either on or off is seldom more than one per cent. Ask us to send you our guarantee.

SIMPLICITY

The McEwen was designed for simplicity and this point has been carefully preserved .All parts are built to guage, are interchangeable and every part of the machine can be readily gotten at for cleaning and overhauling. Simple positive take-ups and adjustments are provided wherever necessary.

STRENGTH

The ability to stand up under hard usage is a distinguishing feature of the McEwen, Compactness and rigidity of design, careful selection of materials, combined with constant and severe inspection of every part, all ensure strength and exceptional reliability in the finished engine.

USE

The McEwen has a particular field in driving electric generators for lighting, power, street railway and mine haulage. Built in simple and compound units up to 700 H.P.

Why the C.P.R. North Toronto Route to Ottawa and Montreal is the Logical One

The train leaves as follows:

Leave North Parkdale - - -	9.15 p.m.	Leave West Toronto - - - -	9.30 p.m.
Arrive North Toronto - - -	9.40 p.m.	Leave North Toronto - - -	10.00 p.m.
Arrive Ottawa, 6.50 a.m.		Arrive Montreal, 7.00 a.m.	
Daily.		Double Electric Berth Lights.	

¶ The residents of Toronto are adjacent to either North Parkdale, West Toronto or North Toronto stations, same being easily accessible and close to residential districts.

¶ The North Toronto route is over an hour faster and overcomes a long hill climb for the train out of Toronto obviating any inconvenience and ensuring early arrival at Montreal and Ottawa.

¶ The roadbed has been improved till it is unexcelled in Canada. Practically half the line is double tracked.

¶ The equipment is "Canadian Pacific Standard," a synonym for the "best" and attentive porters, ensure efficient service.

THE ALCHEMIST.

The alchemist is not dead. He crops up ever and anon, filled with dreams of things every whit as beautiful as the elixir of life or the fountain of youth. When he butts into the domain of metallurgy his visions are weird. As they appear in the public press, touched up by the reprehensible reporter, they suggest to us the possible joint offerings of Peruna and Mrs. Eddy.

Some years ago, an enterprising Toronto dentist, yclept Dr. J. S. Island, gave up his profession and turned his resourceful mind towards metallurgical experiments. We do not know how deeply Dr. Island studied the metallurgical literature and practice of to-day. From internal evidence we are inclined to believe that he relied upon his own God-given ability, and not upon the records of work already done. He looked upon himself as truly an intellectual island, isolated, intact, unteachable.

Be this as it may, Dr. Island won ready recognition. Stirring newspaper paragraphs have appeared occasionally, until, as climax, the Canadian Courier (a National Weekly!) gave him a full page of journalese on September 9th, 1911.

Our readers are earnestly requested to consider these glittering extracts from the Courier's pages:

"For years Dr. Island has been trying to solve one "problem—the reduction of low grade ores. In Co- "balt, Porcupine, California, and Alasaka [Editor's "Note.—This applies equally well to the whole ter- "restrial sphere.] tons of mineral wealth are going to "waste. Only a fraction of the precious metals stored "there by nature has been utilized. Mining methods "to-date are inadequate. [Editor's Note.—We are "glad to learn this. It is news of the first water. We "had not suspected that our mining engineers were "not doing their duty. Shame on them!] The miner "digs out rich veins and sends these ores, containing "from 5,000 ounces of gold, silver, or copper to the "ton, to be smelted. Lower grade ores, which run "about fifteen ounces to the ton, [Editor's Note.— "Mark, pray you, the nice distinction between high "and low grade ores.] he throws on the dump, because "the cost of reduction is too great. Now Dr. Island "aims at making it worth while to salvage these low- "grade ores. Seventy per cent. of low-grade ores are "composed of insolubles. Dr. Island's method is to "make soluble salts out of them. . . . He runs them "through an ore crusher. Then he places them into "specially constructed tanks. Mixed with water they "are stirred by a propeller until a creamy lather

"arises. [Editor's Note.—The creamy lather, no doubt, " is ingeniously devised to assist in shaving profits.] "Then the mass is permeated by chlorine and sulphur "dioxide gas, prepared in generators of Dr. Island's "own design. The hard ores have now become solu- "ble salts and it is no longer a difficult job to extract "the principal metals from the baser in the salt for- "mation."

So far the technical side of things. Next the Courier touches on matters financial to this effect:—"One "day a promoter hit upon the Island building, and "saw the dentist's operations. He had insomnia for "a few days, and spent the time dogging the footsteps "of Sir Donald Mann, with whom he had a bowing "acquaintance. Sir Donald ran out to Island's place. ". . . . Now Sir Donald has formed a ten-million- "dollar company to boost Island's invention." Thus the Courier.

From all available facts it may be fairly deduced that Dr. Island is treading the road that the first-year youth travels when he is initiated into the mysteries of qualitative analysis. The "horror of odours," we quote the Courier's phrase, is one of the perquisites of the adolescent investigator.

Yet we do not wish to scoff at Dr. Island. He may be a genius, and he may be merely a misguided and mistaken inventor. The chances are largely in favour of the latter alternative. But the most serious phase of the whole business is the fact that Dr. Island permits the public press to exploit him and his process before he has given one iota of tangible proof that he can get commercial results. If Dr. Island were a professional metallurgist he would have lost caste at once. As matters stand, it is only possible to say that, whatever the improbable merits of his process, he is countenancing the worst kind of wild-catting in connection with the flotation of his company.

The Courier's statement that Sir Donald Mann "has formed a ten-million-dollar company to boost Island's invention," we disregard entirely. Sir Donald is too wise a bird to be caught with chaff. He has made a conditional offer. The condition is that Dr. Island perform up to the limit of his promises. The fulfilment of that condition would bring more than ten million dollars from any magnate.

* * * *

A commission of technical men is shortly to investigate the Island process. We do not know that the report, if unfavourable, will be made public. But, whether that report be favourable or unfavourable, the self-respect of the inventor and of those associated with him should preclude the publication of such fatuous nonsense as the Courier has spread abroad, and common honesty should prevent the promoters from selling any shares.

A COMMISSION FOR NOVA SCOTIA'S GOL MINES.

Seven years ago the Government of Nova Scotia gaged Mr. T. A. Rickard (who as mining enginee editor, and as author needs no introduction to readers) to make a cursory examination of the mines of the province. Mr. Rickard came and w and no one was the wiser. His report was never lished. According to the Government, the report unpublishable. According to Mr. Rickard, the ernment should have published his report. With question, however, we have nothing to do. It is n sary only to mention that the non-publication of Rickard's report has had a most mischievous e upon Nova Scotian gold mining. The colour of report is not known to the public. Yet it is taken granted that Mr. Rickard expressed a strongly verse opinion in regard to the future of gold minin the Province. That there is absolutely no ground this belief, does not modify the current misconcep

As there is no probability of Mr. Rickard's nouncement being made public, the only pos course is to disregard it altogether. It is unprofita at this late date, to attempt to allocate the resp bility for the fiasco. The urgent duty of the Gov ment is to make a strong effort to appraise the pre value and the future prospects of each gold produ district in the Province.

An appropriately selected commission compose mining men whose names carry weight and w judgment may be thoroughly relied upon. Such a mission, amply supplied with funds, and provided every facility for examining the representative mines, would be in a position to learn much conc ing the industry.

We believe sincerely that the report of a prop constituted commission would place Nova Sco gold mining in a very favourable light. Of co everything will depend upon the personnel of the mission, and upon the authority with which i clothed.

In selecting the members of the commission it is perative that men of world-wide experience in mining be selected. It is equally necessary tha Nova Scotian mining man be chosen. Everybody terested will also agree that the inclusion of Mr. F banlt, whose knowledge of the whole subject fro geological standpoint is at once complete and ac ate, is necessary.

The duties of the commission should consist in m ing an abstract of the history of each district, in scribing the present condition of every mine, in d nosing the whole industry, and in formulating a whereby Government assistance can be best app

The open publication of the report of this com sion would rouse world-wide interest. The mi fraternity is waiting for it. It is the obvious dut the Provincial authorities to act at once. The Rick

dent itself has committed the Government so completely that continued silence is as impossible as it undignified.

THE EVANS-STANSFIELD DIRECT STEEL PROCESS.

At the Canadian National Exhibition, the annual function that gives fame to Toronto, there was given an unusually interesting metallurgical demonstration. On the evening of Friday, September 8th, and during the morning and afternoon of Saturday, September 9th, Mr. J. W. Evans exhibited his electric furnace in actual operation.

Under the most adverse conditions, and handicaped by an almost total absence of facilities, Mr. Evans succeeded in reducing small quantities of titaniferous iron ore to steel of the best quality. The Friday test was begun with a cold furnace and with an uncontrolled current. Nevertheless, after five hours, the small charge of ore, amounting to less than 100 pounds, was reduced and clean ingots of steel were produced. The Saturday run was much more successful.

Mr. Evans has attacked manfully the problem of making steel direct from titanium-bearing iron ores. Ever since 1904, his time and energy have been unreservedly devoted to the development of a suitable furnace. With the aid of Dr. Stansfield he has evolved a plant that is, apparently, a commercial success.

This means much for Canada. There are many known deposits of titaniferous iron ore. No serious attempt has been made to utilize these. It is known that most of these ore bodies carry a small percentage of vanadium. Sometimes, also, nickel is one of the associated elements. As the electric furnace designed by Mr. Evans is strictly controllable, the desired proportions of titanium in the alloy can always be obtained. The steel inherits nearly all the vanadium and nickel.

Physically, the steel turned out from Mr. Evans' furnace is free from defect. Occluded gases are absent. There are no flaws, neither are there signs of segregation. The product appears to be thoroughly homogeneous. In effect it is a valuable steel alloy possessing all the attributes that are required for a high-speed tool steel.

Credit is due the Canadian National Exhibition and the Ontario Bureau of Mines for assisting Mr. Evans in making his public demonstration. Credit also is due to Mr. Evans for the plucky manner in which he has stuck to the discouraging task of making people believe that there is something in his invention. For more than seven years he has been engaged in perfecting his furnace. He has reached the stage at which he is ready to submit his claims to the most rigorous examination. Unlike the average inventor, he has made no appeal to the investing public, although his process has met the approval of all who have looked into it.

That the Canadian National Exhibition should have been the first Canadian corporation to enable the inventor to exhibit his process is gratifying. It is, incidentally, a sign that the directors will succeed in their aim. Sooner or later they will make the Exhibition an international event.

The example set by Mr. Evans should be followed by others. Among the vast crowds that throng the Exhibition annually are many who are interested in mining. A "process" exhibit is always instructive. No description can carry the same meaning to the reader. The person who once sees ore being crushed and treated has always a peg upon which to hang further information. The manufacturer of machinery who does not realize this is losing a supreme opportunity.

To return to our subject, if Mr. Evans has solved the riddle of cheap direct steel, and we believe that he has, he has placed a premium upon numerous hitherto worthless ore bodies in Ontario and Quebec.

MINING IN QUEBEC DURING 1910.

A distinct improvement upon all its predecessors is the Annual Report of the Mines Branch of the Province of Quebec. Although the date of distribution has been very much delayed owing to causes beyond the control of the Department, yet it contains much material the timeliness of which is not impaired.

The total value of Quebec's mineral production during 1910 was $7,323,281, as compared with $5,552,062 during 1909 — an increase of $1,671,219. Mr. Denis attributes this increase in part to the more complete collection of data. Nevertheless, the greater part of it may be assigned to larger outputs. For instance, the value of asbestos produced during 1910 was $2,667,829, as against $2,296,584 in the year 1909. The figure for cement was $1,954,646, as compared with $1,314,551; for brick, $906,375, as compared with $584,371; and for limestone $503,173, as compared with $457,143. Granite, marble, mica, and a few other minerals show gains. The grand total is by far the highest yet reached by the Province.

Asbestos mining was carried on very actively during the first seven months of the year. Slackening demand caused the production to fall during the remainder of the year. Mr. Denis explains that this condition is only temporary.

Titaniferous iron ore was mined for the first time since the year 1872. From the large bodies of this ore at St. Urbain, 3,596 tons were shipped. A quantity of this was used by the General Electric Company, at Lynn, Massachusetts, in connection with the manufacture of electrodes for arc lights. The titanic acid content is reported to have been from 45 per cent. to 50 per cent. The remainder of the St. Urbain shipments

were consigned to the Titanium Alloy Co., Niagara Falls, N.Y. Mr. Denis devotes considerable space to the subject of titanium-bearing ores.

The cupriferous iron pyrites deposits of the Eastern Townships are the principal sources of copper. Only 24,040 tons were mined in 1910, a fall of 10,000 tons from the output of 1909. The present year will see much larger production as the McDonald mine, near Weedon, is shipping steadily. Last year the bulk of the ore came from the Eustis mine.

Gold is being won this year from the alluvial deposits on the Rigaud-Vaudreil Seigniory, Beauce County. The operators, under the name of the Dominion Gold Fields, Limited, possess mining rights over 70,000 acres, including much rich territory from which most of the gold extracted in the sixties and seventies was obtained.

Shipments of graphite amounting to 309,400 pounds, valued at $15,896, were made from two mines in the township of Buckingham—the Buckingham Graphite Co., and the Bell Graphite Co. This is the largest yearly production on record.

Mica mining, also, became much stronger. The value of the shipments, mainly from the townships of Templeton and Portland in Ottawa county, was $58,668. This recovery is needed. In the year 1907, the value was $223,878.

The mining of chromite in the Eastern Townships was practically dead throughout the year, only 299 tons being shipped from old stock-piles.

The output of building materials and clay products was much larger than ever before. Brick increased 55 per cent. as compared with 1909; lime, more than 100 per cent.; granite, 90 per cent.; marble, 16 per cent.; limestone, 10 per cent.; and cement, 48 per cent. As mentioned above, a part of these increases must be set down to more complete collection of data.

7,923 men were employed during the year in the mines and quarries of the province. The number of fatalities was 14—a death rate of 1.76 per thousand men employed. This is a most creditable showing.

The report includes notes on the Opasatica District, a geological reconnaisance in Gaspe, and a chapter on the handling of explosives. It is well illustrated, and carefully printed. The CANADIAN MINING JOURNAL congratulates Superintendent Denis and his staff upon setting a higher standard.

THE MAGPIE MINE.

Dr. W. L. Goodwin's article in this number of the CANADIAN MINING JOURNAL should attract immediate attention. The utilization of enormous deposits of siderite, which in its natural condition carries only 40 per cent. of iron and is contaminated with nearly 4 per cent. of sulphur, is a bold stroke.

Long experimenting, conducted under the direction of Mr. R. W. Seelye, for the Lake Superior Corporation, has demonstrated that this ore can be roasted sweet. The calcined product is a strong porous lump ore, carrying more than 50 per cent. of iron, practically free from sulphur, and of Bessemer quality.

The plant that is to be erected is fully described by Dr. Goodwin. Some millions of tons of ore have been developed by diamond drilling. The conversion of this ore into a high-grade product will be accomplished at the rate of 15 tons per hour, and at a cost not to exceed 40 cents per ton. This will be a truly notable addition to the available ore supplies of Canada.

The calcining of siderite was performed on a small scale, a considerable number of years ago, at Londonderry, Nova Scotia, near which place there are large bodies of the mixed carbonates. But the two calciners were of hardly more than experimental size, and the cost of operation was too high.

The enterprise of Mr. Seelye has made possible a revolutionary step in advance, a step that will go far towards securing the future of the Lake Superior Corporation.

KILDONAN.

One more blasted hope is on record. His Grace the Duke of Sutherland, who owns large estates in Sutherlandshire, Scotland, consented to have his Kildonan property exploited for alluvial gold. The contract was given to a man named Heath, a former Klondike prospector. Heath succeeded in stirring things up a bit. But that was the only result. No gold of any importance was found, despite the windy hopes of Heath.

The crofters and shepherds who, for the nonce, had become transmogrified into miners, have now returned to their more peaceful vocations. Kildonan is no longer a name wherewith to conjure.

ONTARIO METALLIFEROUS MINES.

Returns to the Ontario Bureau of Mines for the first six months of the current year are more than usually gratifying. Whilst the production of copper and nickel has fallen off, the output of silver is greater by 2,417,142 ounces than it was during the corresponding period last year. The amount of iron ore mined was 94,803 tons, or 55,306 tons in excess of the quantity mined during the former half of 1910. Gold once more appears on the list, 2,276 ounces having been extracted up to June 30th, 1911.

EDITORIAL NOTES.

The net profits of the International Coal & Coke Company, Coleman, Alberta, for the calendar year 1910, amounted to $300,097. The company pays four quarterly dividends at the rate of 1½ per cent., or 6 per cent. per annum.

CORRESPONDENCE

A WARNING.

Toronto, September 11th, 1911.

The Editor,
CANADIAN MINING JOURNAL,
17-23 Manning Arcade Annex, Toronto.

Sir,—My attention has been called to a statement in the publicity section of the Swastika number of "The Mining Investor," refrering to me as having examined the claims of the Porcupine Swastika Mining Company, Limited, and reported favourably upon them; also referring to me as the Managing Director of that Company. I write to say that the statement that I have reported favourably upon the claims of the company is contrary to fact; and I am not, and have not, at any time, been Managing Director ,or otherwise officially associated with the company; or a shareholder therein, or otherwise interested in the stock of the company. If further reference is made to me in any of these connections, I shall be compelled to place the matter in the hands of my legal adviser, and take such proceedings against parties responsible therefor as may be necessary to protect my interest. Kindly interest. Kindly insert in your next issue, and oblige,

Yours truly,

R. B. LAMB.

Personal and General

Mr. J. W. Evans was in personal charge of the Evans-Stansfield electric smelter at the Canadian National Exhibition, and superintended the public demonstrations, of which an account will be found in another page.

Mr. Stanley N. Graham has resigned his position as superintendent of the Canada Sulphur Ore Company, Queensboro, Ont., and has accepted an appointment in connection with the Geological Survey, Ottawa.

Dr. Milton L. Hersey has been nominated as Liberal candidate to oppose Mr. H. B. Ames in St. Antoine division of Montreal.

Mr Francis H. Shepherd, of Nanaimo, B.C., has resigned the position of Chief Inspector of Mines for British Columbia to accept the nomination as Conservative candidate to oppose Mr. Ralph Smith, a supporter of the Liberal Government, in the constituency of Nanaimo, Vancouver Island.

Hon. Wm. Templeman, Dominion Minister of Mines, who at the last Federal election was defeated in Victoria by Mr. G. H. Barnard, and was afterwards elected for Comox-Atlin, also in British Columbia, is again opposing Mr. Barnard as candidate for Victoria.

Mr. A. D. Clabon, formerly of Quebec, but now of Vancouver, B.C., recently took to Princess Royal Island, B.C., a party of mining men to see a gold property he and associates are developing on that island.

Dr. R. W. Brock, of the Geological Survey of Canada, went to British Columbia about the middle of August. Late in the month he visited the Skeena district, where, in the vicinity of Hazelton, silver-lead ores have been found.

Mr. G. G. S. Lindsey went to British Columbia last month with Mr. L. Reyersbach, managing director of the Central Mining and Investment Corporation, London, England, and Mr. Hugh F. Marriott, the company's consulting engineer. Dr. R. W. Brock, Director of the Geological Survey of Canada, accompanied the party west. Messrs. Lindsey and Marriott paid a short visit to the Skeena country, and afterwards went to Sheep Creek camp, Nelson mining division.

Dr. Heinrich Ries, Professor of Economic Geology, Cornell University, Ithaca, N.Y., has been examining clay deposits in British Columbia, to obtain information for inclusion in a report on the clays of western Canada he is to make to the Canada Department of Mines. He went thence to San Francisco, on his homeward journey.

Mr. Anthony J. McMillan, liquidator of the Le Roi Mining Company, Limited, was in Chicago last month on his return trip from London to Rossland, B.C.

Mr. Byron N. White, owner of the Pueblo copper mine, near Whitehorse, southern Yukon, has returned to Spokane, Washington, from a visit to the mine, which, however, he will not again work until he shall be granted lowed freight rates on ore from mine to an outside smeltery.

Mr. J. W. Astley, mining engineer, formerly manager of several important mines in British Columbia, including Le Roi, has taken an office in one of the rooms occupied by the CANADIAN MINING JOURNAL, 17-23 Manning Arcade Annex, Toronto.

Mr. Clifford E. Smith, mining engineer, Brockville, Ont., has recovered from a severe attack of throat trouble. Mr. Smith was a patient at the Toronto General Hospital for ten days.

Mr. J. W. Rawlins, chief chemist to the Canadian Copper Company, was in Toronto on September 5.

Mr. W. J. Woolsey, consulting mining engineer, Thetford Mines, P.Q., left on August 26th for a two months' professional visit to Great Britain and Europe. His address while away will be 98 Leadenhill Street, London, E.C.

Mr. John Redington has been appointed manager of the Swastika mine in place of Mr. M. W. Summerhayes, who has resigned to take up private practice.

Mr. R. S. Lamb, mining engineer, Toronto, is making an extended series of examinations in Porcupine.

Mr. M. W. Summerhayes has resigned from the management of the Swastika mine, and will take up private practice again. Temporary address will be 76 Home Life Building, Toronto.

TOPAZ, TIN, AND GRANITES IN ONTARIO

By Willet G. Miller.*

Mr. R. W. Broek, in his interesting paper, "Tin and Topaz in New Brunswick," published in the September 1st issue of the JOURNAL, says that the recent discovery of topaz in New Brunswick is the second to be made of this mineral in Canada. It may be of interest to refer to another occurrence of this, insofar as Canada is eoneerned, rare mineral.

Last summer, 1910, Dr. E. S. Moore was engaged by the Ontario Bureau of Mines to make an examination of the Sturgeon Lake gold field in northwestern Ontario. In his report, now being published in the 20th annual volume of the Bureau of Mines, he has the folfowing to say eoncerning the oeeurrenee of topaz in that field. Apparently Dr. Moore did not recognize the mineral in hand specimens but only on examination of a thin section under the microscope. If topaz does oeeur in a form in which it can be reeognized in hand specimens at Sturgeon Lake or elsewhere, it may easily be passed over. Unless it oecurs in distinct erystals it is apt to be mistaken for quartz or other light-coloured mineral.

Topaz and Other Minerals in Hornblende Syenite.

"Lying along the eastern shore of the upper portion of the narows on the lake, there is a large mass of rock which in appearanee much resembles a light coloured gabbro and has been mapped as gabbro on the Canadian Geologieal Survey's map. It appears much darker in some parts than in others, but in all the speeimens examined the feldspars appear to be of the potash species, and one seetion showed a very little quartz, so that the rock is a syenite. It has much the appearance of some nephelite syenites, though mieroscopic observations failed to show the presenee of any nephelite.

"The megaseopie characters of the roek are a grey colour, phanerocrystalline texture, crystals of pyrite, hornblende and good eleavage faces of feldspar resembling plagioclase but laeking any sign of striations dne to twinning.

"Under the mieroseope one seetion is eomposed of the following minerals: orthoclase, mieroeline, green hornblende, a little biotite, and a small qnantity of miea the pleoehroism of whieh would identify it as zinnwaldite. The relation of this miea to the other minerals suggests that it has been introdueed into the rock from an external sonrce. Titanite in prismatie form and in acute rhombie sections in fairly eommon, and small erystals of it are frequently enelosed in the erystals of hornblende. A eonsiderable amount of topaz is present and it shows as a eolourless, slightly higher bi-refringent mineral than quartz, filling spaces between the feldspars and in places it appears to have replaeed portions of these minerals. Fluorite varying in colour from blue, violet, to eolourless is quite eommon. It is found in some eases as irregular streaks, but also as little eubes. It oecurs as small crystals in orthoelase, fills holes in topaz, and occupies eraeks in the other minerals or the interstiees between various erystals. Apatite is found in small erystals and pyrite and magnetite in small quantity. Other thin sections show orthoelase, mieroeline, green hornblende, a little albite, small erystals of augite, apatite, a little tourmaline, eonsiderable titanite, caleite, flnorite, topaz, and a small proportion of quartz.

"As mentioned in a previous section a pit in syenite reveals a calcite vein with which are associated apatite, tourmaline, hornblende, zireon, pyrite, chalcopyrite.

"In the presence of so many fluorine, boron, titanium minerals we have good evidenee of rather extensive fumarole aetion. On the eooling of the magma fraeturing on a small seale must have oeeurred which permitted the boron and fluorine gases to rise through the roek and replace some of the other minerals by new minerals. The quartz and calcite veins would be due to solntions filling some of these eraeks.

"On aeeount of eertain petrographie similarities between them it seems probable that these syenites belong to the same petrographie provinee as the granites a little farther north, but represent a basie phase of the parent magma."

The New Brnnswiek topaz deseribed by Mr. Broek is found in assoeiation with granite dikes (greiss) near the border of a granite intrusive mass. The British Columbia oeeurrence referred to by him exhibits topaz in a rock whieh he ealls granodiorite; while, as has just been said, the Sturgeon Lake topaz occurs in syenite. The prospeetor, however, need not bother with fine distinctions as regards the names of rocks. Granite, granodiorite and syenite are elosely related.

In so far as the writer knows, tin has been found only in two localities in Ontario, viz.: Sudbury and the township of Lyndoch in Renfrew County. At Sudbury about four per eent. of oxide of tin has been found in the rare mineral sperrylite. Fourteen years ago, in Lyndoch, the writer discovered a mineral of the rare eolnmbite group assoeiated with beryl, anorthozonite or green feldspar, tourmaline, garnets and other minerals. The eolumbite and assoeiated minerals occur in a coarse-grained granite, or pegmatite, dike. The pereentage of oxide of tin in the mineral, found in the analysis, was 0.92, or nearly one per eent.*

Varieties and Ages of Ontario Granites.

Since tin occurs in association with granites or related roeks, it would be of economie importance to have a more eomplete knowledge of the eharacter and age relations of the granites of the province. Such knowledge would also be useful in eonneetion with other ore deposits. For instanee, in the reports and annotated maps which the Bureau has published on the Porcupine area, Mr. A. G. Burrows and the writer have expressed the view that the gold-bearing quartz veins are in all likelihood genetieally assoeiated with granite intrusions. It is not neeessary to reeite the various reasons which led to this theory of origin. It may be said that as field work in that area progresses, eonfirmatory data as to the theory of the origin of the ores are being obtained. During the present summer Mr. Burrows, who is in eharge of the field work for the Bureau, has found that there are two series of eonglomerates, one of whieh is older than the surrounding intrusive granites and the other young.

*Provineial Geologist, Bureau of Mines, Ontario.

*7th Report Ont. Bureau of Mines, p. 236.

r. Burrows' first year's work he observed that conglomerate, in the belt extending from near Dome mine northeastward to the vicinity of Three ns Lake and beyond, was much more disturbed, ng at high angles, and more highly metamor-ed than the conglomerate in which the rich silver , at Cobalt occur. Moreover, gold-bearing veins found in this series of conglomerate and asso-d sedimentary rocks not only at the Dome mine also near Three Nations Lake. The problem then —if the quartz veins are genetically connected a granite intrusive, of what age is the intrusive? Burrows has, however, found conglomerate in the thern part of the township of Langmuir which is ved by erosion from the granite in that vicinity. conglomerate has been little disturbed, lying al-horizontally, and is much less highly metamor-sed than that in the Dome mine — Three Nations e belt. He therefore concludes that the granite h gave rise to the gold-quartz veins is younger the latter conglomerate and that it is older than Langmuir conglomerate. There may, however, be ites of two or three ages in the area.

n the shores of Lake Temiskaming and to the hward there are conglomerates which have the earance of those at Porcupine. One series dips at angles and shows other evidence of much greater urbance than does a second series such as that in ch the productive veins occur at Cobalt.

n the region surrounding Lake Superior, where the pre-Cambrian rocks have been closely studied in numerous localities, granites of various ages are known which intrude even the youngest of the pre-Cambrian sedimentary rocks.

At Cobalt, Elk Lake, and Gowganda there are certain types of granites, which occur as dikes and are commonly known as aplites or granophyres, which are genetically related to the quartz diabase that is associated with the cobalt-silver deposits. These rocks of the granite family are believed to represent the end product of the diabase eruption. Similarly at Sudbury granites or granophyres are closely associated in origin with the norite of the nickel-copper deposits. Those who have closely studied the Sudbury area believe that these granite-like rocks are simply a differentiation from the magma or molten mass which gave rise to the norite and the nickel-copper ores. From what has been said it will be seen that the character and age relations of our granites have an economic bearing.

Knowing that topaz and other minerals had been found at the New Brunswick locality and that these minerals are characteristic of deposits in which tinstone occurs, Mr. Brock made a search for this ore and found it. A similar search should be made in the Sturgeon Lake area. Since there are granites and related rocks of so many characters and ages in Ontario the prospector for tin may some day be rewarded.

Sizing for Plate Amalgamation.

By P. N. Nissen.

While sizing for concentration is a recognized necessity, have not possibilities in amalgamation been overlooked? There is one difficulty in saving the coarser gold or minerals, but efforts to recover the finer particles of gold are attended with but indifferent results. In many cases these finer particles are not liberated from the gangue, while in other cases, though liberated, they are of such microscopic fineness that the utmost delicacy is required in the manipulation of the process used. Over-refinement of the plant, however, can easily be the outcome of an honest desire to accomplish the best economic results; but it must always be borne in mind that enterprise in this direction should be limited by commercial considerations.

In many cases a large percentage of the gold occurs in a finely divided state, so that the losses are extreme by the methods of amalgamation now most commonly practised. But, on the other hand, the tendency to get away from amalgamation entirely is to be regretted. Should we not rather try to improve our methods by working along logical lines than entirely disregard the affinity of quicksilver for gold and the simple and easy means for their subsequent separation? While the expansion of the cyanide process has been extremely rapid it has been changed and improved only in physical details, the basic principle being unchanged in its simplicity. Similar development is possible in amalgamation; for, while the development of the cyanide process has been the most important phase of metallurgy in our generation, it has its manifest limitations.

Gold amalgamation is closely associated with stamp milling because this method of crushing is the almost universal means of reducing gold bearing ores. The tendency, however, has been to increase the duty of the stamps without providing larger plate area for the pulp. When we were crushing smaller tonnages per stamp our recoveries by amalgamation were higher. A smaller volume of pulp was run over the plates, necessitating the use of less water. Thus, the liberated gold was given more opportunity to settle to the surface of the plate and become amalgamated. With the increased volume of pulp, due to the increased duty of the stamps, the finer particles of liberated gold pass more rapidly over the plate, the larger percentage of coarser particles of sand being underneath and next to the surface. The finer sand and gold, being carried along on the surface of the stream, do not come in contact with the quicksilver. Scouring of plates, loss of amalgam, and loss of fine float gold are thus brought about.

The placer miner has long recognized that he can make no satisfactory recovery of finely divided gold without first getting rid of the larger boulders and gravel, then treating the finer sands separately. If this principle applies to the operation of the sluice-box and dredge, the same principle must necessarily be followed in the treatment of all sizes of sand and gold particles down to the most minute atoms.

Of late years the erroneous practice of merely lengthening battery plates has obtained. It is evident that no improvement in amalgamation can arise from this expedient, since, if the pulp still travels at the same speed, the conditions remain the same; or, if the

velocity be lessened, a blanket of coarse sand will form on the plate. On the other hand, the evident need is for a reduction of velocity by means of wider plates.

In some of the gold mills in the western United States it is the practice to divert all the pulp from a five-stamp battery to one side of the already insufficient apron plate, while the other portion is being dressed. This is done to avoid hanging up the stamps. A high amalgamation recovery is expected, and the management prides itself on avoiding loss. But, as a matter of fact, loss is inevitable. It is much saner to hang up all the stamps for a sufficient length of time to permit of dressing the plates properly. rather than crowd a small section of plate with more than it can handle. Indeed, this is merely equivalent to sluicing so much gold and amalgam onto the dump.

To retard the flow of the pulp in some way is necessary. The management of the great Homestake mine has attempted this by adding plates of greater width, so that they now have forty feet of plates before each five-stamp battery; but each succeeding ten feet from the battery downwards is about a foot wider than the preceding one. Thus the pulp is thinned out to a great extent, and the results have more than justified their installation and the necessary labour to care for them.

It seems reasonable, therefore, that we separate or size our pulp into several ranges of sizes, then flow each size over plates arranged with regard to area, slope, and proper amount of water to the amount of pulp of that size being made by the stamp. The accompanying table will give a fair average of the pulp from a stamp battery crushing through a 0.024 or 30-mesh screen.

Percentage of battery pulp remaining on given screens

Screen	On 50,	80,	100,	150,	200	pass 200.
Per cent. of pulp	8.5,	10.5,	7.0,	8.0,	3.0,	63.0.

It will be observed that only 8.5 per cent. of this pulp is coarser than 50 mesh. The movement of 91.5 per cent. over the ordinary plate as used is dependent entirely on the few coarser particles 8.5.

Our coarser pulp will contain our coarser gold, and will, therefore, be more easily caught on a plate having a fair grade, while each succeeding smaller size can be put over plates of greater width and less grade, thus giving the finer gold particles a better opportunity to come in contact with the mercury and be amalgamated. It is important that the grade of plates should be as slight as possible, especially for the finer sands, to allow sufficient contact with the plate to insure amalgamation. Moreover, plates set at a low angle hold the mercury much better than those set at a higher angle. It must also be borne in mind that the constant flow of sand and water downwards causes the mercury to be forced along and finally over the bottom of the plate. The numerous varieties of amalgam traps in use is justification for this statement. The steeper the plate and the larger the volume of pulp of mixed sizes flowing over it, the greater will be tendency. Where we have loss of mercury we must have loss of gold.

While the number of amalgamating machines of sorts is legion, and the efficiency of most of them ni will be observed that in a large number of these ap ances any amalgamating plates used are arranged tically. The inventors have overlooked the fact t mercury is liquid and requires a more or less h zontal plate to rest upon. The result is that most the mercury intended to adhere to these plates will found in the bottom of the apparatus in a foul c dition.

One of the most essential features in amalgamat is clean mercury, therefore it is necessary to have surface over which the gold is run clean and bri at all times. Copper amalgamating plates are sim and accessible for dressing and they are always un direct observation. No mechanical motion need given them. They can be situated in a separate ro or building, accessible only to the direct attenda This fact is a consideration of no small importa It is upon the returns from these plates that the r enue of the mine is dependent, so that the fewer dividuals on which the responsibility is placed of curing all the gold that is recovered, the less liabil there will be for losses. Any investment made in s ficient plates for the proper equipment is in no w extravagant, for they are always worth as much more than they originally cost. Every ounce of g run over them leaves a certain small portion in plate. They do not wear out nor have to be "scr ped" as would occur with mechanical appliances.

Few small mines can afford cyanide plants wh depend upon skilful, therefore high priced chemi for satisfactory extraction. The returns from th small plants in most cases represent less than the erating cost, owing to the small tonnage handled. cyanide plant to be operated must be complete. T same number of tanks, fittings, etc., being greatly t of proportion in a small installation than in a la one. It, therefore, seems apparent that improvem in simple amalgamation is most urgently needed. a the possibilities will well warrant our most care consideration and efforts. Since sizing has done much for concentration the possibilities offered in application to amalgamation seem many and most viting.

The plates should be arranged in pairs to allow being dressed or cleaned while the pulp is being r over the other, and thus not interfere with the pro flow of pulp. By this arrangement the plates can kept in perfect condition by constant dressing, th being ample time for this work to be thoroughly d instead of the usual rush common in present practi where it is seldom properly performed.

On the Slate Industry in Southern Quebec.*

By John A. Dresser, Ottawa.
(Annual Meeting, Quebec, 1911.)

The slate deposits of commercial importance in southern Quebec as far as known are all of sedimentary origin. The black slate are of Ordovician, and the coloured of Cambrian age. In a number of pla quarries were opened between thirty and fifty ye ago; but most of them were soon closed from one ca or another, principally, it would appear, from an sufficient market at the time they were worked. present the market conditions have apparen

*Published by permission of the Director of the Geological Survey of Canada.

aged greatly for the better and the slate deposits ght properly receive renewed attention.

General Geology.

hree anticlinal ridges of crystalline rocks, prob- of Pre-Cambrian age and mainly of volcanic or- extend in a north-easterly direction through hern Quebec, and form the Sutton Mountain, Stoke ntain, and Lake Megantic hills. The basins be- en these ranges of hills, are each about 25 miles in th and are in general underlain by rocks of Cam- n age around their borders, while Ordovician stra- ccupy the central and greater part of the bearings. the east side of the Sutton range a belt of serpen- and related intrusive rocks occur along or near contact of the Cambrian and Ordovician sediments. the Ordovician, near the contact with the serpen- , several of the most important slate deposits of district are found. There are other deposits in Ordovician and in the Cambrian that are not situ- near intrusive rocks; but hitherto all the produc- of commercial importance has been from those osits near the serpentine.

are the New Rockland quarry in Melbourne, range IV., lot 23; the Melbourne or Walton quarry, Melbourne, range VI., lot 22; the Steele or Bedard quarry in Cleveland, range XV., lot 6, and the Danville quarry in Shipton, range IV., lot 7. The distance between New Rockland and Danville (the extreme points) is about fifteen miles, but the slate-bearing formation continues for a much greater distance.

These quarries were most actively operated in 1889, in which year they were described by Dr. R. W. Ells,† as follows: "The largest slate quarry at present in operation in Quebec is that of the New Rockland company. This was first opened in 1868 and has been worked almost continuously ever since. It is situated on a rise with an elevation of about 500 feet above the St. Francis River, which is four miles distant to the north, and has at present a working bench 200 feet deep. The slate cleaves readily, is very free from pyrites, impervious to water and equal in every respect to the celebrated Welsh slates. . . . To the northeast of this is situated the old Melbourne or Walton quarry, on lot 22, range VI., Melbourne, about two miles distant from the St. Francis River. This quarry was

ig. 1.—New Rockland Slate Quarry, Looking Northeast. This quarry is some 799 feet in length, 75 feet wide, and nearly 200 feet deep. The cleavage of the slate dips at a high angle to the Southeast.

Black Slates — Ordovician.—The "black" slates e all of Ordovician age, being the argillaceous part the lower Trenton (Farnham) formation. They are dark or bluish grey colour and generally have an cellent cleavage which dips nearly vertically and y be at any angle to the bedding planes. In gen- al character and geological position they correspond the slates of Montpelier and Northfield in Vermont. ey have hitherto been the principal source of pro- ction in Canada, and are the only slates quarried Quebec for several years past.

Details of Some Deposits — Four of the best known posits of slates of this type occur near the contact th serpentine in the County of Richmond. These opened by the late Mr. Walton in 1860 and was worked for about eighteen years, when it was closed. A very large quantity of slate was extracted of a quality similar to that of the New Rockland quarry, and the workings were of very considerable size, being stated, in the catalogue of the Paris Exhibition to be 150 feet deep, 300 feet long and 100 feet broad.

"The failure of the industry at this place was to a large extent due to the depression of the market at that time and a lack of capital necessary to carry out the work with modern equipment. Both these quar-

†An. Rept. Geol. Survey of Canada, 1889. Part K, pp. 128, et seq.

ries are in contact on the west side with large masses of serpentine. The slates here found are continuous across the River St. Francis into Cleveland and Shipton. The oldest quarry in this belt is that on lot 6, range XV. (Cleveland) formerly known as the Steele quarry, which was opened in 1854. No returns are to hand from this quarry under its new management, but the quality of the slate extracted is excellent in so far as yet tested. The output of the Danville quarry is as yet almost entirely confined to school slates, for which a ready market is obtained.

"Of all these slates it may be generally said that their quality is unsurpassed. Their chemical composition is very similar to that of the slates from Angers in France which have been in use in buildings in Montreal for considerably more than one hundred years."

The New Rockland, Melbourne, and Steele quarries are so close to the contact of the serpentine intrusion that the slate is probably altered in some measure thereby. (Fig. 2). The Danville quarry, which appears to be in slate of the same original composition, is sufficiently distant from the contact to be probably unaffected by it.

The slate of Danville, judging from evidences now available, is softer and not so strong as that from the other quarries. The original bedding planes may be detected (Fig. 3) in places and in trimming the slate often "scallops" along them. On the other hand it Rockland only has been in operation for the last fifteen years. The major part of the production quoted on a subsequent page is to be credited to this quarry, which has been in operation since 1868.

The production at present is wholly confined to the roofing slate. The quality is well proven by its satisfactory use for the past forty years.

The following chemical analyses give a comparative view of the composition of several roofing slates of this series and one from Germany. The analyses are quoted from various reports of the Geological Survey:

	New Rockland.	Melbourne	Danville	Westbury	Lehesten, Germany
SiO	65.39	64.20	61.80	65.85	67.5
Al_2O_3..	15.97	16.80	13.48	16.65	17.3
FeO	4.66	4.23	10.10	5.31	7.4
MnO	.39	.....	.74	.....	....
CaO	.67	.73	1.06	.59	1.1
MgO	2.99	3.94	4.52	2.95	2.6
K_2O	3.60	3.26	1.71	3.74	1.9
Na_2O..	3.33	3.07	1.46	1.31	....
H_2O	3.26	3.40	4.86	3.10	4.6
	100.26	99.63		99.50	99.7

Slate has been worked unsuccessfully in Orford, range V., lot 2, in the County of Sherbrooke, where the

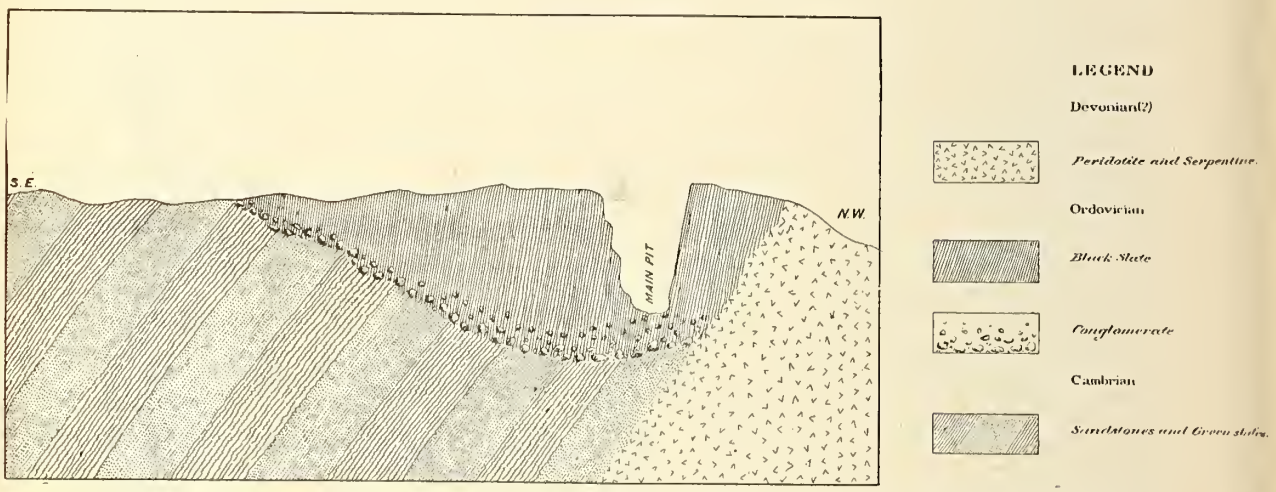

Fig. 2—Diagrammatic section across the New Rockland slate quarry. The pit is about 200 feet deep.

seems to be an excellent material for school slates and other manufactures on account of its greater softness. Also the quarry itself is freer from quartz veins, which latter in the other quarries are more numerous near the contact with the serpentine than at a short distance from it.

Nearness to the contact is thus both a favourable and an unfavourable feature. Dykes and quartz veins are more numerous near it and where the alteration has been too great, the slate becomes "sharp" or is nearly a hornstone. On the other hand, slates beyond the effects of the contact have less hardness and strength. The most favourable location for slate seems to be in the outer part of the contact zone, near enough the intrusion to secure strong slate and far enough away from it that the spaces between the "flints" are sufficiently large to be advantageously worked.

The Melbourne, New Rockland, and Danville quarries have been importantly productive; but the New slate appears to be very similar to that at Danville. The cause of the closing of the quarry some four years ago has not been learned; but at that time the market demand was doubtless insufficient. As has been pointed out by Sir W. E. Logan, in a report of the Geological Survey on this district, published in 1863, a similar slate is well exposed in Brompton, range V., lot 29, near the village of Bromptonville. Both of these properties, though containing a soft slate, probably warrant investigation at the present time.

Other localities in which slates of this character occur are reported in range I., lot 14, the Township of Halifax, County of Megantic, in Westbury, near the St. Francis River, and near St. Victor de Tring, in the County of Beauce.

On the south side of Lang Lake, in the County of Temiscouata,* slate was exposed by a cutting on the

*Summary Report of the Geological Survey, 1908, p.

ional Transcontinental Railway which promises to of excellent quality and in ample quantity. Holds have been purchased in the locality by Messrs. Fizer and Davies, the operators of the New Rockland sle quarry, and development operations, it is expected will be inaugurated early during the present year. This locality is about 200 miles east northeast of the Danville slate quarry. It is not certainly known whether this slate is of Ordovician or of Silurian age.

Coloured Slates — Cambrian. — The slates usually referred to as "coloured" are red, green, mottled, or purple, and are prevailingly coarser in texture and do not split as finely as the black slates. Coloured slates have never been extensively quarried in Canada; but in the United States a considerable production is maintained. Almost the entire production of the State of Vermont at the present time is obtained from the coloured slates of Cambrian age.

Details of Some Deposits.

Coloured slates are known to occur in several localities in the Province of Quebec and between 25 and 50 years ago, some of these quarries were productive to a small extent.

	Kingsey	Peach Bottom, Penn.
SiO_2	54.80	55.88
Al_2O_3	23.15	21.85
FeO	9.58	9.03
CaO	1.06	.16
MgO	2.16	1.49
K_2O	3.37	3.64
Na_2O	2.22	.46
H_2O	3.90	3.39
	100.24	

On lot 26, range V., in the Township of Acton, County of Bagot, the Rankin quarry was operated in 1875-6, and produced some quantity of red and green slate.

Coloured slates have also been opened on lot 18, range X., of Brompton and on the IVth range of Melbourne about half a mile, southeast of the New Rockland quarry in the County of Richmond, on the 2nd lot of the Xth range of Brampton in the County of Dorchester, on the XVth range of Garthby, lots 8 and 9, County of Wolfe, at Mawcook, near Granby, in Shefford County, and at other places in the Cambrian rocks.

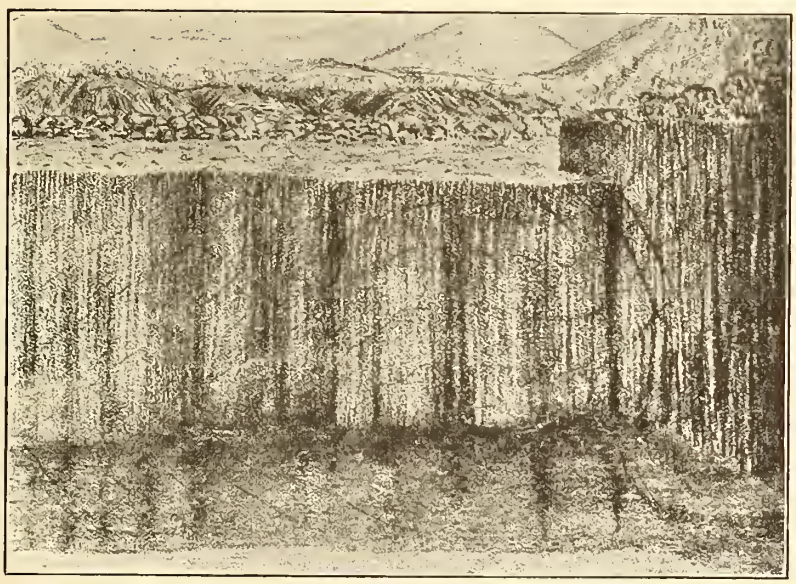

Fig. 3—Sketch of the Southwest Wall of the Danville Slate Quarry. The cleavage is nearly vertical; while the original bedding planes can be seen dipping in folds towards the Southeast.

In Kingsey, range I., lot 4, County of Drummond, a quarry was opened in 1857 and closed two years later. The slate is principally purple, although some green and mottled varieties appear. The colour is well preserved on slates split at about that time showing that they belong to the "unfading" class. The deposit is large and apparently the working conditions are favourable. A railway has been graded to the Grand Trunk Railway at a point two miles from Richmond station, and four miles from the quarry.

The following analysis of slate from this locality was made by T. Sterry Hunt in 1852 and the accompanying analysis of the Peach Bottom roofing slate of Pennsylvania, is added for comparison. These analyses are quoted from Kemp's "Handbook of Rocks."

Quarrying and Dressing.

The rock is quarried and cut down in benches in open pits, and after being assorted in the pit, material suitable for splitting is hoisted and sent to the splitting sheds. Here it is cut, split, and trimmed to the sizes required or to which it is best adapted. Slate is bought and sold by the "square," that is in quantity sufficient to cover 100 square feet after allowance has been made for all overlapping. The usual thickness in Quebec is 3-16 inch. The sizes vary from 12 inches x 24 inches to 6 inches x 12 inches.

In the coloured slate quarries of Vermont much of the roofing slate is split to a greater thickness—from

¼ inch to 1¼ inches. The price varies with the thickness, an increase of about $2 per square being allowed for each additional ¼ inch. Thus slates ¼ inch thick might be sold for $6 per square, whereas one inch slate would be worth as much as $12 per square. These thicker slates must be bored and countersunk to carry nails or bolts, while thin slates merely require to be punched.

Quarrying and dressing of slate involve handling a large percentage of rock waste. Even in the best deposits only slate that will split in a definite direction and may be cut to definite sizes can be utilized. In addition to the loss in trimming and splitting, breakage from the blasting of rock, which falls from the high benches to lower levels, must also be considered.

Again, slate once frozen, if not split while frozen, is valueless and necessitates the removal of a covering of sap rock every spring. The waste from these sources added to the large quantity of defective rock remaining to be removed reduces the percentage of slate recovered of the total rock handled to a very small proportion — probably between 5 per cent. and 10 per cent.

Review of the Industry.

Canada. — The only slate produced in Canada for some years has been obtained from the Eastern Townships of Quebec, where it has been continuously quarried since 1860. Nova Scotia, New Brunswick, and Ontario have yielded slate at different times and promising developments are reported from British Columbia; but as far as can be learned there is no production from these provinces at the present time.

The following statements of the values of the production and imports of slate into Canada during the past twenty-one years are obtained from the annual reports on the Mineral Production of Canada by Mr. John McLeish, Chief of the Division of Mineral Resources and Statistics, Department of Mines, Ottawa.

Slate Industry in Southern Quebec—Dresser.

Year	Production.	Imports.
1889	$119,161	$ 41,370
1890	100,250	22,871
1891	65,000	46,104
1892	69,070	50,441
1893	90,825	51,179
1894	75,550	29,267
1895	58,900	19,471
1896	53,370	24,176
1897	42,800	21,615
1898	40,791	24,907
1899	33,406	33,101
1900	12,100	53,707
1901	9,980	72,187
1902	19,200	72,601
1903	22,040	84,437
1904	23,247	86,057
1905	21,568	93,228
1906	24,446	112,941
1907	20,056 –9 mths	95,520
1908	13,496	131,069
1909	19,000	135,221

Some slate has been exported during the above period; but the amounts have been comparatively small and so irregular that they may be neglected in considering the industry as a whole.

The year 1889 shows the greatest production also the largest consumption in the history of slate industry in Canada. The exports of that year amounted to $3,303 in value. In 1909, a year of small production the imports reached the highest, and consumption the second highest place. The value of exports in that year was $612.

Broadly speaking, production declined from 1889 to 1901, followed by a small and somewhat irregular advance. The imports decreased somewhat irregularly from 1889 to 1895, and since that date have steadily increased to the highest figures yet reached. At present, therefore, the production is scarcely more than 14 per cent. of the consumption.

Concerning the supply and demand Mr. McLeish remarks* "That there is a more extensive market in Canada than is supplied by slate from Canadian sources is shown by the following statistics of imports. The total value of the imports of slate in 1909 was $135,221, of which $71,914 was roofing slate and $34,085 school writing slate. The imports of roofing slate, school writing slates, and manufactures of slate are chiefly from the United States. Some roofing slate is also imported from Great Britain, while slate pencils come principally from Germany and the United States."

During the past twenty years the prices of slate have advanced about in proportion to the increased cost of labour.

The duty on slate entering Canada is: 25 per cent. on roofing slate—not to exceed 75 cents per square; and 30 per cent. on manufactured slate.

In the schedule of the proposed Reciprocity Agreement, the duty on roofing slate is 55 cents per square.

All the Canadian output at present is used for roofing purposes.

The United States. — In the United States official returns for the year 1908 show a production valued at $6,316,817. Of this value, $5,186,167 is in roofing slate and $1,130,650 in mill stock for various manufactures. Of this amount Pennsylvania produced nearly 62 per cent., or a value of $3,902,958; Vermont, 27 per cent. or $1,710,491; Maines, 3⅓ per cent., or $213,707. Almost the entire production comes from the eastern Atlantic States. Vermont and Maine are the States most suitably comparable to Quebec in their geological conditions; and slate producing formations of both extend into Canada.

Uses of Slate.

The principal uses of slate are for roof covering, writing slates, floors, electric switchboards, billiard tables, blackboards, mantels, wainscotting, laboratory tables, lavatories, sinks, and similar purposes. All the Canadian output and about 80 per cent. of the production of the United States are used for roofing. Slate was formerly manufactured for other purposes than roofing in Canada at the quarries of New Rockland and Danville; but this was discontinued some fifteen years ago. The consumption in Canada for 1909 was approximately as follows:

Roofing slate	$90,914
School slate	34,085
Slate pencils	6,154
Manufactures	23,068
	$154,221

*Op. cit.

Qualities of Slate.

In a recent and exhaustive report on the slate deposits and industry of the United States, T. Nelson Dale* gives the following classification of slates:

CLASSIFICATION OF SLATE.

A. Aqueous sedimentary.
(a) Clay slates; matrix without any or with faint aggregate polarization.
(b) Mica slates; matrix with marked aggregate polarization.
1) Fading: with sufficient Fe CO_3 to discolour.
(a) Carbonaceous or graphitic.
(b) Chloritic (greenish).
(c) Hematitic and chloritic (purplish).
2) Unffading: without sufficient Fe Co_3 to produce a but very slight discolouration on prolonged exposure.
(a) Graphitic.
(b) Hematite (reddish).
(c) Chloritic (greenish).
(d) Hematitic and chloritic (purplish).
B. Igneous.
(a) Ash slates.
(b) Dyke slates.

The slates of southern Quebec as far as known belong to the following divisions of the classification given above:

A. Aqueous sedimentary.
(b) Mica slates.
2) Unfading (a) Graphitic — black — Ordovician.
(b) Hematitic—red—Cambrian.
(c) Chloritic—green—Cambrian.
(d) Hematitic and Chloritic—purple—Cambrian.

The black slates are strictly speaking phyllites, that is slay slates with a small percentage of mica. But as the strength of the slate depends largely on the amount present, those slates which are strong enough to be useful are conveniently classed as mica slates, to distinguish them commercially from those so poor in mica as to be of little or no value.

The mica in these slates is not an original mineral but is developed chiefly from feldspar by alteration due to pressure perhaps accompanied by heat. It is in very minute scales, only a few thousandths of an inch in thickness; but the overlapping of these scales of mica is supposed to give to slates the elasticity that enable them to be split.

The above classification is based on certain general properties that effect the commercial value of slate; but it does not take into account all the features that determine its value. A degree of cleavage such that the may be easily split to the required thinness, strength, freedom from injurious constituents, and from excessive jointing are also important features.

Good cleavage is the first essential. Not only must there be a cleavage that will enable the slate to be readily split, but there must be an absence of cross or oblique cleavage generally called "slant" by the quarrymen, which not only interferes with the splitting, but still more lessens the strength of the slate.

Strength depends primarily on the degree of compression in a single direction with uniformity of composition and texture and in some cases on metamorphism by igneous contact. Recrystallization, especially the development of secondary mica, induced by pressure and heat, characterizes the strongest slates. Where the alteration has been insufficient, the slate trims unevenely or "scallops" often by breaking along original bedding planes.

Amongst injurious constituents carbonate of iron, or carbonate of iron, magnesium, and lime, cause discolouration when slates are exposed to the weather and so produce the "fading" slates. Iron pyrites rusts, causing spots and holes in slate. Magnetite makes slate less useful or even unsuitable for electric switchboards. Quartz veins have a similar effect even when small enough not to lessen the strength of the slate. Quartz veins, "flints" are a very common cause of poor quality in slate, and in any considerable quantity render it useless. Slates that are too siliceous (as from extreme metamorphism) even where no quartz veins are formed, become brittle and impossible to use. They are then known as "sharp" slates.

Porous slates of open texture, are unsuitable for uses that expose them to moisture, such as in making lavatories. They also shatter more readily if exposed to frost.

General Considerations and Conclusions.

Deposits of slate that may be profitably worked are comparatively few and small. The overburden of "sap" rock which must be removed before uncovering slate of real splitting qualities and strength is generally deep — fifteen to twenty feet, at least, and in places much more. Great care must, therefore, be taken in selecting a location for a quarry and a considerable outlay of capital is necessary to develop such a property. Transportation is also a very important factor to be considered in the establishment and operation of a slate quarry.

Nevertheless the extension of roads and railways, the increasing cost of lumber, the introduction of the modern class of large steel-frame fireproof buildings in cities and the consequent use of thick slates — conditions that even twenty years ago were not obtaining —afford commercial advantages to the slate industry to-day that it did not previously enjoy.

Hence, speaking generally, the steadily growing market and the successful development of a large industry in similar geological formations in the neighbouring States of Vermont and Maine, seem to warrant investigation by investors of the slate deposits of eastern Canada and especially those of southern Quebec.

Discussion.

Mr. Ferrier:—I have listened with peculiar interest to Mr. Dresser's interesting paper, and it has recalled many things I had almost forgotten since I was sent to make an examination of the New Rockland slate quarry in 1886. I notice that Mr. Dresser was exceedingly careful in his description of the peculiar terms employed by the quarrymen. I found that some of the terms used by the Welsh quarrymen were much more shocking.

I recognized after I had made my examination that much of the trouble in connection with the marketing of slate was due to a disregard to proper sorting, in consequence of which the material shipped was not always of an uniform and high grade character. I thoroughly agree that the zone from which the first-class material can be produced is a comparatively narrow one.

There is another feature to which Mr. Dresser did not especially direct attention, and a matter responsible for much trouble in the employment of slate for

*Dale, T. Nelson, and others.—"Slate deposits and slate industry of the United States;" Bull. U. S. Geological Survey, No. 275, 1906, pp. 5-6; also Annual Report U. S. G. S., Vol. XX., 1897-8.

roofing. After purchasing slate for roofing purposes, one is at the mercy of the roofer. A careless workman may be the means of causing even the finest slate to show a bad record. With a shingle roof a defect is easily remedied; but this is not the case with slate.

I fully agree with Mr. Dresser's view that a great deal can and will be done to develop the slate industry in Canada, and bring about the more general utilization of slate as a roofing material.

Dr. Porter: There was one point in Mr. Dresser's paper which seemed to be rather significant and that was the comparatively small size of the quarry which he described and apparently of the other quarries. Anyone who has visited the quarries in Wales or France, and some in Pennsylvania, will have noticed the enormous size of the workable areas, which eventually permit of installation and operation of large works. It would be interesting if Mr. Dresser could indicate whether in any parts of the Eastern Township there have been discovered slates of presumably good quality in such large masses to warant the establishment of big enterprises.

Mr. Dresser: The coloured slates occur in bodies great enough for large scale operations. The black slates of the best quality, however, are not as yet known in larger masses than those already worked.

Mr. Ferrier: As Mr. Dresser is much more conversant than myself with recent developments, I would ask him if he could bring out the point which I know was a serious one when I was connected with that investigation, namely, the difficulty experienced by local enterprises of competing with the cheaper grades of slate from some of the larger quarries abroad?

Mr. Dresser: I could not say what grades of slate are being imported in competition. They seem to find, however, a ready market and the work here is carried on at present in a rather small way. Meanwhile, the present duty on slate is 25 per cent., but not to exceed 75 cents per square. In the proposed Reciprocity agreement, this is amended to a flat rate of 55 cents per square. The importation comes largely from the United States, with the exception of a comparatively small quantity, valued at about $6,000, of slate pencils, imported, I understand, from Germany. Our people, I believe, at present are unable to meet our own market requirements.

An Appeal to the People of Ontario and all Interested in the Gowganda District.

[Editor's Note.—The following petition, a copy of which was forwarded to the JOURNAL by Mr. G. M. Colvocoresses, manager of the Millerett Silver Mining Company, Limited, sets forth what is considered to be a genuine grievance. We may say that we feel convinced that substantial justice has not been done to the Gowganda region. The region has a well-defined claim upon the people and the Government of Ontario, a claim that cannot reasonably be ignored.]

After repeated requests by the mine owners and residents of Gowganda the Minister of Public Works has finally written that the Ontario Government positively refuse to expend any money whatever on the Elk Lake-Gowganda wagon road which at the present time is in a deporable and practically impassable condition.

The Ontario Road Inspector in a report to the Minister stated that the road was in a wretched shape and that approximately $6,000 should be expended to complete it and make it reasonably passable.

Mr. A. A. Cole, mining engineer for the T. & N. O. Railroad, who has made a thorough study of the Gowganda district since the early days of the camp, recently made a report to the Minister of Lands, Forests and Mines, in which he showed by figures that Gowganda had been and continued to be one of the most valuable feeders for the T. & N. O. Railroad and in order to assist its development he recommended that a good road should be completed and kept in condition by the Provincial Government. It is believed that every person who has visited and inspected this camp is firmly convinced that in the interest of the whole province Gowganda should be assisted to the extent of providing it with proper transportation facilities usable alike during the winter and summer months.

We believe that the people of Ontario are not aware of the existing conditions at Gowganda and do not appreciate that all the activities of this district are being handicapped most severely by the lack of proper transportation. It might be of interest to call their attention to the fact that there is at present more silver ore being mined in the camp than at any time during its history and that at the present time it is not possible to ship a good part of this production out to the railroad. The mines of the camp are now turning out 50 tons per month of high grade ore and concentrates valued in the neighbourhood of $25,000, and during the past three months the shipments have been held down to approximately half of this quantity. A heavy team of draught horses now require four days to haul 1,500 pounds of ore to the railroad, while over a fair good road the same team would easily draw out 3,000 pounds in two days.

It might also be well to state that owing to the fact that we are in the Forest Reserve and in an unorganized territory, it is impossible to legally levy a tax for the improvement of the road, therefore in order that we should not be absolutely isolated it has become necessary for a few of the mines and citizens of the camp to voluntarily contribute funds which are being carefully expended in keeping the road in a barely passable condition. We feel that there are a great many people who would like to help in this work and we therefore make an appeal to all those interested in Gowganda and the neighbouring districts and to those who believe that these camps should be given a fair chance to develop and add their production to the mineral wealth of Canada. We ask you to give us what assistance you can by bringing this matter to the attention of your local members and requesting that they should use their influence to secure a grant from the Ontario Parliament for the completion of the government road, and in the meantime if you should feel like giving us financial help all subscriptions will be gratefully received by the Secretary of the "Gowganda Road Committee," care of Canadian Bank of Commerce, Gowganda, Ont.

Dated this 24th day of August, 1911.

Titanium-Vanadium Tool Steel Direct from Titaniferous Iron Ore.

Written for the CANADIAN MINING JOURNAL.

In the year 1904, Mr. J. W. Evans, of Belleville, Ont., began a series of experiments with a view to finding a use for the titaniferous iron ores of Canada. Recognizing the impracticability of smelting these ores in the blast furnace, Mr. Evans devoted his efforts altogether to devising an electric furnace that would meet the rathe runusual requirements of the case. In less than a year, he succeeded in obtaining directly from these ores a high carbon, titanium tool steel, a steel markedly superior to ordinary tool steel.

J. W. Evans

At the 1906 annual meeting of the Canadian Mining Institute, in the city of Quebec, Mr. Evans read a paper on the subject of making steel direct from iron ores. Here, also, he exhibited a few small tools made from steel of his own manufacture. At this time he was working with a small experimental electric furnace in his laboratory at Belleville The next step was to construct a larger furnace. This one proved so successful that it was found that molten steel could now be poured into moulds the size for lathe tools, and that the steel was easily superior to ordinary tool steel and approached the quality of high speed steel.

In 1909, Dr. Stansfield, professor of metallurgy, McGill University, visited Mr. Evans' plant in Belleville, and spent some time in looking into the process. During this visit several successful heats were run. The outcome was that Dr. Stansfield entered into a technical partnership with Mr. Evans, and added to the plant design a pre-heater of his own devising whereby the waste gases from the electric furnace are utilized to pre-heat and partly reduce the ores. The whole process was then re-christened the Evans-Stansfield Direct Electric Smelting Process.

A furnace, with capacity of about one-half a ton of steel in 24 hours, was then built at McGill Univer-

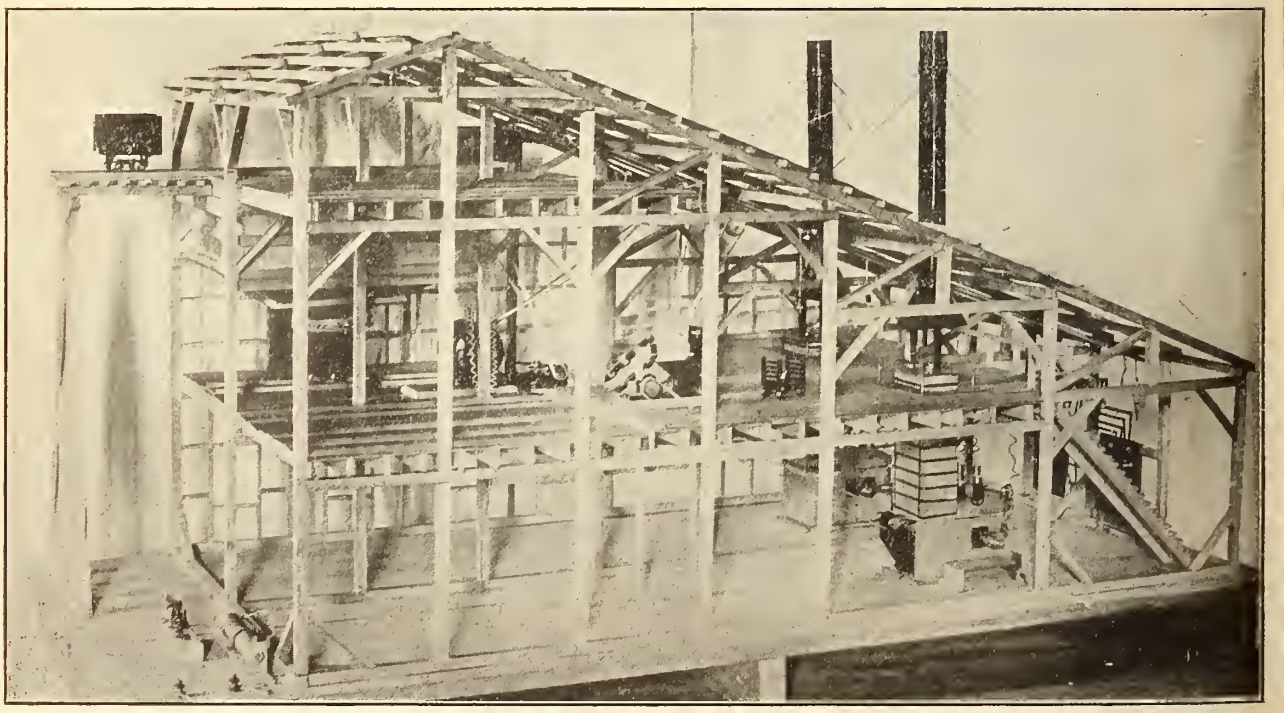
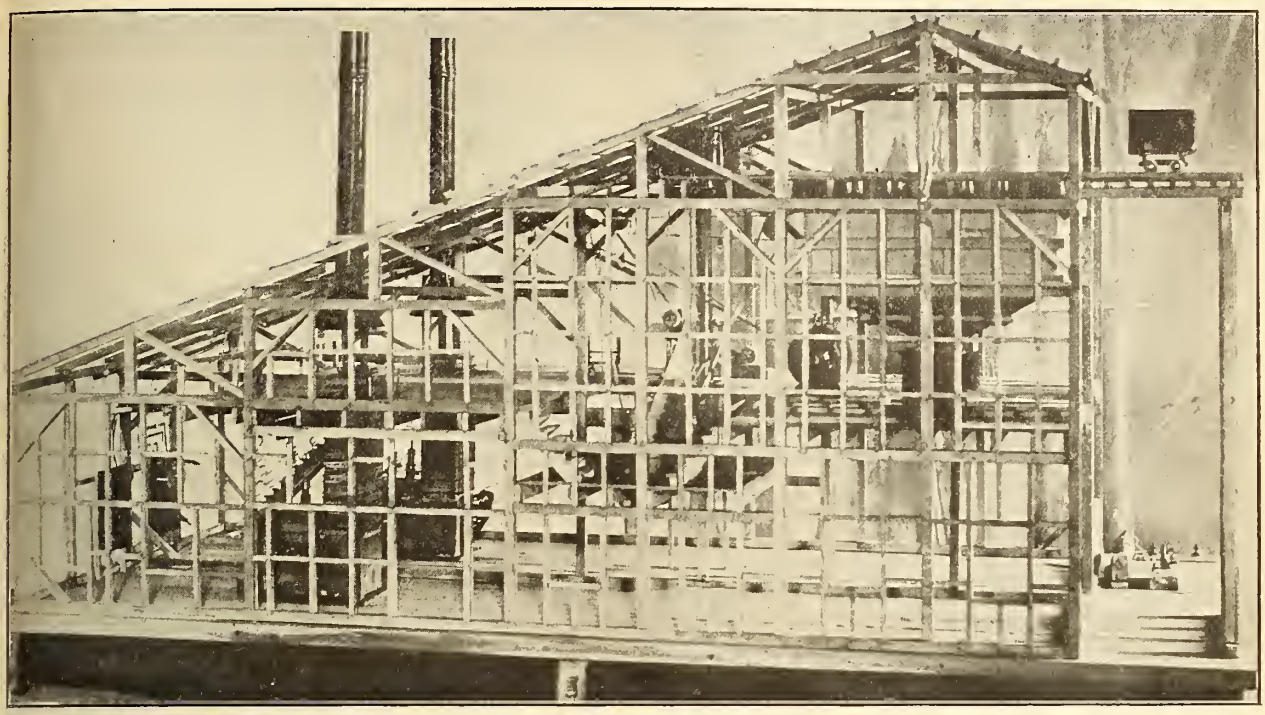
Evans-Stansfield furnace and pre-heater.



Model of Mill



Another View of Model

It is this furnace that was used in the public demonstration at the Toronto Canadian National Exhibition.

The accompanying cuts show the patent sketches (for patent specifications see CANADIAN MINING JOURNAL, August 1, 1911)), and the model of a mill designed by Mr. Evans.

In actual work, the titaniferous iron ore is ground, mixed with suitable proportions of lime and charcoal, briquetted, and fed into the pre-heater. From the preheater it goes into the hearth of the furnace. Here reduction is completed in a few hours. The furnace is continuous in operation. Almost the theoretical quantity of metal in the ore is obtained in the form of steel, the last drop of which can be poured from the furnace into the ladle and from the ladle into the molds.

There is reason to believe that this process will revolutionize the art of steel making. It renders feasible the manufacture of titanium-steel rails and structural steel direct from hitherto useless tianiferous iron ores. The items of cost are the strongest point. It is claimed, and apparently there is little room for doubt as to the accuracy of this claim, that the total cost per pound of steel, when the furnace is in continuous operation, will fall considerably under the present figure in existing large plants.

It is estimated that more than half the iron ores in Ontario and Quebec are titaniferous, and it has been proved that they make a better class of steel than the non-titaniferous ores. They cannot be used in the blast furnace. But they are wonderfully adapted to the electric furnace.

The Distribution and Uses of Titanium Ores.

(From the Bulletin of the Imperial Institute.)

Titanium has come into prominence largely owing to its application in the manufacture of steel, and since ores of this metal occur in many of the British colonies, a resume of the information available regarding the distribution of its ores and methods for their utilization is now given.

Titanium in the metallic form does not occur in nature, but in the form of titanic oxide (TiO_2) it is one of the most widely distributed elements of the earth's crust. Rutile, the commonest natural form of titanic oxide, is rarely found in large deposits, but enormous quantities of ilmenite or titaniferous iron ore carrying varying amounts of titanic oxide are known to occur in many localities, and these two minerals are those which have been utilized as sources of titanium.

Rutile is known to occur compact or massive in igneous, sedimentary, and metamorphic rocks: it varies in colour from yellow to reddish-brown and black, and gives a pale brown streak. The hardness is about 6.5 and specific gravity 4.2 to 4.3. The mineral usually contains 98 to 99 per cent. of titanic oxide and from 1 to 2 per cent. of ferric oxide.

Ilmenite or titaniferous iron ore is an iron-black mineral occurring massive or in the form of thin plates or grains. Its hardness is 5 to 6, specific gravity 4.5 to 5.0, and lustre submetallic. The fracture is conchoidal, and streag brownish-red to black. Its composition is represented by the formula FeO, TiO_2 which corresponds to 47.3 per cent. of ferrous oxide and 52.7 per cent. of titanic oxide.

Other minerals containing a large percentage of titanium are titanite or sphene, which is calcium titanium silicate, and brookite and octahedrite, crystalline forms of titanic oxide.

Distribution of Titanium Ores.

In view of the present very limited utilization of these ores only those deposits which are or have been worked to any extent will be described in this article.

Europe—The principal rutile-producing deposits in Europe are those of Kragero, to the northeast of Kristiansund in Norway. The annual production averages about 50 tons of nearly pure rutile besides a certain amount of lower grade material (Min. Industry, 1908, 17, 823).

America.—Rutile is obtained at Roseland, near Arrington, Nelson Co., Va., U.S.A., from pegmatite dykes, of which it constitutes about 4 per cent. The dykes consist chiefly of orthoclase and albite feldspars together with blue quartz. The soil covering the deposits also contains some rutile and is utilized as a source of the mineral. The plant in operation includes a 10-stamp mill, engines, pumps, concentrating tables, and a Wetherill magnetic separator. The final concentrate contains on the average about 98.4 per cent. of titanic oxide (Min. Res., U.S.A., 1908, Part I., p. 744). Several dykes yielding ilmeno-rutile (a mineral containing varying amounts of iron and titanic oxides) and apatite occur in this locality, one being about 30 feet thick and half a mile in length. These deposits may become of value as a source of titanium for purposes where the presence of small quantities of phosphorus is not objectionable.

Well-crystallized rutile is also obtained in Chester Co., Pa., but the amount is small and is usually sold to collectors.

Other important occurrences of rutile in the United States are situated in Lincoln and Habersham Counties (Georgia), Warwick County, New York), and Warren County (Maine).

Australia.—Rutile occurs, and has been worked in a desultory fashion for many years, in the hundred of Talunga, about 6 miles north of Blumberg, A. Australia (Rec. Mines, S. Australia, 1908, 4th edition, p. 356). The workings, which are about 150 yards in length, consist of small shafts and trenches in a kaolinized dyke formation from 10 to 12 feet wide, striking slightly east of south. Rutile crystals of varying size occur distributed throughout this matrix, and can be extracted by panning. On the surface for some distance on either side of this formation fine rutile can be obtained. The mineral also occurs in a small seam of gravel about 12 inches below the surface. The average yield from these workings amounts to about 1¼ per cent. of the material treated. The deposits appear to have been prospected only to a very limited extent. Nearly 2,000 pounds of rutile were produced at Para Wira in 1907 from 2,000 tons of gravel. Rutile occurs at a number of other localities in this State, but has not been worked.

Small quantities of rutile, which is stated to be almost entirely free from iron, are also produced from time to time in Queensland.

The Utilization of Titanium Ores.

At the present time the chief use of titanium ore is probably as a source of titanium-iron alloy to be used for the purification of steel and iron. The method employed for obtaining the alloy consists in the use of molten aluminium as a reducing agent (Rossi, Electrochem. Industry, 1903, 1, 523). The titanife iron ore is charged into a bath of molten alumin kept fused in an electric furnace. The iron is red first and in this the titanium, as it is reduced by aluminium, dissolves, yielding ferro-titanium. If tile is used, scrap iron is charged into the bath be the mineral.

By this means alloys containing from 10 to 75 cent. of titanium and only 0.12 to 0.75 per cent. of bon can be produced in quantity. Where the pres of carbon in the alloy is not objectionable, the ore be mixed with carbon and reduced in the electric nace. This process gives an alloy containing fro to 8 per cent. of carbon and suitable for treating iron.

Analyses of various samples of ferro-titanium given in the following table (Mineral Industry, 1 9, 720):

	No. 1.	No. 2.	No. 3.	No. 4.	N
	p.c.	p.c.	p.c.	p.c.	
Titanium	10.28	25.11	35.64	53.92	7
Carbon	0.284	0.59	0.75	0.291	
Phosphorus ..	0.09	0.06	0.06	0.059	
Sulphur	0.01	0.011	—	—	

A method of concentration to produce an alloy in titanium from low percentage titaniferous iron has been tried (Electrochem. Industry, 1903, 1, The ore, consisting of 15 per cent. titanic oxide, 8 cent. iron oxide and 5 per cent. gangue, was sm in an electric furnace with just sufficient carbon t duce the iron and leave all the titanic oxide unred in the slag. By this means a good quality pig was produced and a slag in which all the titanic was concentrated. This slag was utilized as a so of titanium for the production of ferro-titanium. alyses Nos. 4 and 5, given in the above table, ref alloys produced in this way.

Ferro-titanium alloys of German origin are us produced by the Goldschmidt process, which co in mixing the oxide to be reduced with finely po ed metallic aluminium and starting interactio means of a fuse. A rapid reaction occurs, and th anic oxide is reduced to the metallic state, the alu ium combining with the liberated oxygen to for umina.

The most important use of ferro-titanium is i purification of steel, particularly for rails. The ence of certain elements in minute quantities in has a far-reaching effect on its quality; and of elements nitrogen is one of the most important. cording to Braune (Stahl und Eisen, 1906, 26, 1431, 1496), the effect of nitrogen is at first slight increase the toughness and reduce the ductility. steel containing from 0.030 to 0.035 per cent. of gen becomes quite brittle, whilst soft steel lose ductility when the amount of nitrogen reaches 0. 0.06 per cent. The presence of nitrogen also fa segregation of the phosphorus and sulphur, ca "cold shortness." Dr. Thorlander (Stahl und E 1909, 29, 1594) found that a steel which normally tained 0.012 to 0.022 per cent. of nitrogen, on "overblown" in a converter, for three minutes, tained 0.032 per cent. of nitrogen.

The removal of the greater proportion of the gen normally found in steel is a matter of muc portance; and it is stated that this can be attain the use of titanium, which combines with nitrog

mperature of 800 deg. C. to form titanium nitrides. nium has a melting-point of 1,850 deg. C. and a ific gravity much less than that of iron; and these sical properties preclude the use of titanium itself, lead to the use of an alloy of titanium and iron ead of the pure metal, which would float on the d steel and be difficult to dissolve. Exhaustive eriments with titanium alloys have shown that the results are obtained with an alloy containing from o 15 per cent. of titanium. The numerous steel ks in the United States which employ ferro-titan- specify an alloy of this composition.

he alloy is added just as the steel runs into the e, i.e., after recarburization and the addition of the ssary ferro-manganese and ferro-silicon. An in- taneous reaction occurs, and after a short time the formed by the reaction (chiefly titanic oxide) s to the surface. According to the experience of on Maltitz, the addition of one-half per cent. of o-titanium, containing 10 to 15 per cent. of titan- , i.e., a maximum consumption of 1.7 pound of tit- um per ton of steel produced, is sufficient in most s to purify steel for rails to the desired extent. The ficial effect of titanium alloy in preventing segre- on of the sulphur, phosphorus, and carbon, and in entrating the blowholes in the pipe cavity, has n demonstrated by the experiments of many well wn metallurgists in America. Improvement was noticed in the working of the steel in the rolling- . The rails produced were found to give much bet- service than ordinary Bessemer steel rails (Ameri- Soc. for Testing Materials, 1910, 10, 201). Tests teel rails laid at a crossing at a New York railway ion showed that in six months the steel treated with o-titanium had lost by flange wear less than one- d of the amount lost by the Bessemer rails which eded them. Interesting comparative tests have n carried out by the Baltimore and Ohio Railway. plain Bessemer rails contained 0.55 and the titan- -treated rails 0.48 per cent. of carbon; each rail hed 90 pounds to the yard. After five months' r on a heavy curve, the plain Bessemer rails had 4.18 pounds per yard, while the titanium-treated s had only lost 1.45 pound per yard. The Besse- rails showed excessive wear and the usual indi- ons of segregation, whilst the treated rails were d and homogeneous (Times, Eng., Suppl., 1909, 26).

he following table, showing the quantities of "spe- " steel rails produced in the United States, indi- s the growing preference for the titanium-treated l rail (Met. and Chem. Eng., 1911, 9, 121):

	1909	1910
	Gro. tons	Gro. tons.
Titanium steel	35,945	195,940
Nichel-chrome steel	12,207	81
Nickel and electric steel	1,464	4,210
Manganese steel	1,028	390
	50,724	200,621

he above quantities, 70 per cent. in 1909 and 87 cent. in 1910 were made from Bessemer steel.

ecent information states that an order for 41,500 of titanium-treated steel rails has been given by New York Central lines, where rails of this type e been under trial for several years past. On these s the rails are subject to great variations in tem- ture, which often falls in winter to 30 degrees w zero. The results of tests on rails employed on ous sections of this line are given in the Journal of Industrial and Engineering Chemistry (1910, 2, 299).

The beneficial effects of using titanium allow for purifying basic open-hearth steel were demonstrated by experiments carried out in the Osnabruck Steel Works (Stahl und Eisen, 1910, 30, 651). In every case the bars treated with alloy showed increased strength, the fracture showing a fibrous structure similar to that of forged iron. In bending tests the titanium-treated steel also gave results superior to those obtained with untreated steel. Improvement was even seen with the addition of such a small quantity of titanium as 0.04 per cent.

In addition to the above-mentioned uses for ferro-titanium as a purifier for steel, it is stated that certain manufacturers of crucible steel in the United States are adding the alloy in sufficient quantity to retain 0.05 to 0.20 per cent. of titanium in the finished steel. This addition is said to increase the toughness and durability of the tool steel produced.

Titanium-iron alloy, containing 5.8 per cent. of carbon, is also used to some extent for improving the quality of iron by removing occluded gases and preventing segregation of subsidiary constituents. The quantity added varies from 1 to 3 pounds of 10 per cent. ferro-titanium to each 1,000 pounds of metal. It has been demonstrated by the experiments of Dr. Moldenke that the improvement is most noticeable in machinery pig (grey) iron (Trans. Amer. Mounds. Ass., 1908, 17, 57). These experiments showed that the average crushing strength of machinery pig iron was increased 52 per cent. by the use of 0.5 per cent. of the ferro-titanium alloy.

Results indicating similar improvements have been recorded when the alloy is added to metal for chilled car wheels, rolls, and to malleable iron. In the case of chilled car-wheel iron, the titanium treatment increases the crushing strength considerably.

The present price of ferro-titanium alloy containing from 10 to 14 per cent. of titanium is about £75 per ton, 150 marks per 100 kilograms (Stahl und Eisen, 1911, 31, 619).

An alloy of copper and titanium, containing from 5 to 12 per cent. of the latter element, is stated to be valuable for addition to copper castings (Min and Sci. Press, 1909, 99, 355). A. J. Rossi recommends the addition of 1 to 2 per cent. of this alloy to the molten copper, as it enables the copper to be cast in sand without difficulty, eliminates oxide and absorbed gases, and gives the metal a close-grained dense structure free from blowholes.

Another form in which titanium is used for purifying metals is that known as "titanium thermit." This consists of a finely powdered mixture of metallic aluminium, oxides of titanium and iron, enclosed in a tin, which is attached to an iron rod and introduced into the ladle immediately after the metal is run from the furnace. Its function is similar to that previously described for ferro-titanium, the oxides of titanium and iron being reduced to the metallic state by interaction with the metallic aluminium.

Alloys of titanium and silicon are also produced for use in the steel industry where it may be desirable to add both these elements. These alloys can be produced containing 5 to 70 per cent. of titanium and 20 to 75 per cent. of silicon by reduction in the electric furnace of suitable quantities of silver sand and pure titanic oxide (Journ. Soc. Chem. Ind., 1910, 29, 636).

Pure titanium, which has a melting point of about

1,850 deg. C. and a specific gravity of 5.17, does not appear to have been put to any industrial use as such.

Smelting of Titaniferous Iron Ores.

Closely connected with the general questions of the utilization of titanium ores is that of the use of iron ores containing small quantities of titanium. The objections made by iron smelters to the use of such material are not that it produces an inferior quality of iron, but that it gives pasty slag, and that the aggregations of titanium nitride and nitrocyanide in the furnaces render working difficult. It is also stated that more fuel is necessary than in the case of non-titaniferous iron ore. At the present time it is difficult to negotiate a sale in the United Kingdom of ore for iron smelting which contains even 2 per cent. of titanic oxide. In the past, highly titaniferous iron ores have been successfully smelted in various localities. An iron company which had works at Norton, near Stockton-on-Tees, many years ago smelted successfully an ore containing 39.2 per cent. of titanic oxide to yield forge iron (Trans. Amer. Inst. Min., Eng., 1882, 11, 159). The fuel and fluxes employed were about 17 cwt. of coke, 12 cwt. of limestone, and 3 to 4 cwt. of basalt, or similarly fusible silicate, per ton of ore. Owing to the uncertainty of the supplies and the small quantity of iron in the ore the work was abandoned.

The question of the smelting of titaniferous iron ore is thoroughly discussed, and the results of many important blast-furnace experiments quoted in an article by A. J. Rossi (Trans. Amer. Inst. Min., Eng., 1892, 21, 832), where he shows that it is possible to obtain a good pig iron and a fluid slag from ores containing 20 per cent. of titanic oxide. Iron ore fairly high in titanic oxide was formerly mined and smelted in Sweden, but the production is stated to have ceased in 1904. In the larger of the Swedish furnaces which smelted this ore, the consumption of fuel is stated to have averaged 275 bushels of charcoal to the ton of ore, a consumption considerably in excess of that required for non-titaniferous ore (Eng. Min. Journ., 1904, 78, 350). Ores carrying a high percentage of titanium were successfully smelted in blast furnaces during a period of 20 years in the Adirondack Mountains, New York State (Stahl und Eisen, 1909, 29, 1593). According to recent information ores from this latter locality rarely contain less than 8 per cent., and often 15 per cent., of titanic oxide (Min. Res.U.S.A., 1908, Pt. 1, 91). The iron ore smelted by the natives of the Salem district, India, by the Catalan process, is stated to carry a certain amount of titanic oxide (Rec. Geol. Sur. India, 1892, 25, 139).

From a review of the literature on this question it would appear that under suitable conditions the smelting of iron ores containing a moderate percentage of titanium should be a commercial possibility, especially as there are enormous quantities of such ore, which is usually very low in phosphorus, obtainable at a low price.

Other Uses of Titanium.

The employment of titanium carbide as an electrode for arc lighting is making progress. According to recent investigations (Trans. Amer. Electrochem. Soc., 1909, 16, 217) this substance gives a high candle-power efficiency. It has been found that the titanium carbide arcs are most satisfactory when operated on a constant current circuit. The electrodes are prepared by grinding the carbide to a fine powder, mixing with a suitable binder, and forcing the paste through a nozzle by means of a hydraulic press. The rods so produced are cut into suitable lengths and dried, first in the air, then in a gas oven, and finally in an electric furnace of the carbon-tube pattern. The electrodes are plated with copper to prevent oxidation during burning. The characteristics of the titanium carbide arc light are an extremely luminous inner path, very little light from the outer mantle, and none from the craters. The electrodes are used as the cathode, while the anode is a rod of copper or carbon. Electrodes of the sub-oxide of titanium prepared by the reduction of rutile have also been tried for arc lighting, but with no great success. At the present time, according to recent information (Mining World, 1910, 33, 2), the most extensively used electrode containing titanium is the so-called "magnetite" arc lamp. This electrode is composed of magnetite, 15 to 20 per cent. of rutile, and some chromite; the first-named giving conductivity to the electrode, the second being the light producer, and the last adding to the life of the electrode.

Titanium has been suggested and tried to a limited extent as a material for filaments for electric glow lamps, the processes of manufacture and use being covered by numerous patents. It is claimed that they give a high candle-power efficiency, and are less sensitive to variations in voltage than other filaments. A trial lot of about 1,000 of these lamps was produced in America in 1906 (Mining World, 1910, 33, 230). A suitable means for the production of such filaments is to force a colloidal solution of titanium hydroxide through a small nozzle, and after drying the thread thus produced to reduce it in hydrogen to the metallic state. It is interesting to note that should there be the slightest trace of carbon present in the filament, such as may get into it from the vaporized oil from the pump during exhaustion, the efficiency of the lamp will be so impaired as to be practically useless (Electrician, 1907, 58, 892).

A process for obtaining pigments from titaniferous iron ore, such as ilmenite, has been described (Journ. Soc. Chem. Ind., 1910, 29, 1023). The ore is roasted at a temperature below incipient fusion and crushed in water, yielding a finely divided product of a yellow to red colour.

Rutile is sometimes added to porcelain tiles to give a soft yellow underglaze colour, and it finds a similar use in the manufacture of artificial teeth. Only the purest varieties can be employed for the latter purpose (Min. Res. U.S.A., 1906, 530).

Pure titanium compounds, particularly the oxalate and the double ammonium oxalate, are used to a limited extent as mordants (Mining World, 1910, 33, 230). They are stated to give with tannin a yellow colour of great durability. Titanous chloride has been used as a mordant and the sulphate as a mordant and "stripper." The double pyrophosphates of titanium with the alkali metals are stated to be capable of application to textiles without damage to the latter.

It has been suggested that titanium nitride, which is produced during the smelting of titaniferous iron ore, should be utilized as a nitrogenous manure, but experiments do not seem to have been made to test the availability of this compound for agricultural purposes.

Commercial Value of Titanium Ores.

According to recent information one of the largest firms producing rutile concentrates in the United States is selling three grades of ore, viz.: grade A.,

taining over 95 per cent. of titanic oxide and practically free from iron, at $160 per ton (2,000 pounds). This grade is stated to be used principally for arc lamp electrodes. Grade B., containing 75 to 80 per cent. of titanic oxide, the balance being largely iron oxide, sells at $80 per ton (2,000 pounds). Grade C., (largely ilmenite), containing 55 to 60 per cent. of titanic oxide, the balance being chiefly iron oxide, sells at $40 per ton (2,000 pounds). Grades B. and C. are stated to be utilized in the production of ferro-titanium.

Manufacturers of ferro-titanium in the United States say that they are utilizing titaniferous iron ore from the Adirondack Mountains, New York State, containing from 14 to 45 per cent. of titanic oxide. The price of thi sore is nominal at $5 to $10 per ton (2,000 pounds) according to the amount of titanium present.

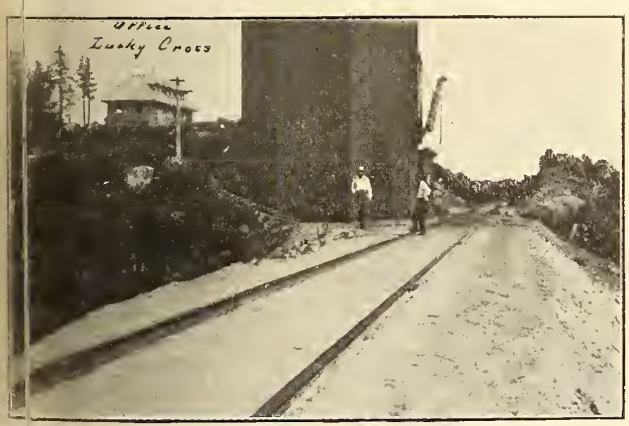
The Lucky Cross Mines, Swastika

Written for the CANADIAN MINING JOURNAL
by J. W. Vandergrift.*

The property now known as the Lucky Cross Mines of Swastika, Limited, was first staked in the year 1905, but the time of the first rush to Larder Lake. Little or nothing was done on it, except the necessary assessment work (which is usually practically nothing), till about two years later when it passed into the hands of the Crawford Mining Syndicate. Just here I would like to say a few things to the average prospector of this north country, and that is—that if he woud spend a greater part of his time, while supposed to be doing assessment work in the bush, doing some actual prospecting, instead of work that has no relation to mining, he would stand a better chance of finding something that would make his property of value. I think the story of what happened here on this property is ample proof of my statement.

* * * *

The Crawford Mining Company erected camps on the bank of Trout Creek and began mining operations at once. They either did not know, or else they ignored the necessity of doing any preliminary surface trenching, and at once began sinking shafts on some of the veins that outcropped, or had been exposed by the action of certain streams of water. In this manner they carried on operations for a part of two years, during which time they sank seven shafts, varying in depth from 6 to 50 feet, and reported having discover-



Office of Lucky Cross

ed say values of from six to twenty-three dollars. This may possibly have been true, if the samples from which the values were recovered were picked samples, but it is not true that they discovered any veins that gave or will give (in the shafts they sank) twenty-three, or even six dollars of an assay value across their entire width.

Throughout the time that they were doing this work they were daily walking over a vein of white quartz,

Part of Townsite Swastika

six feet wide, which did and will assay from $11.20 to $18.60 per ton, and as high as $58 per ton, and which shows visible gold. This was standing right in the path, altogether uncovered and worn by the bootmarks of the people who were looking for gold.

The inevitable result followed, the work was abandoned, and quiet again reigned supreme.

The history of the Swastika mine is practically the same. Operations were started there in exactly the same manner, and in exactly the same manner several thousands of dollars were wasted; the only difference being that in their case they changed their tactics before it was too late, or in other words, before it became impossible to raise any more money, and the finding of gold at the eleventh hour was the sole cause of the activity now going on here.

As has been stated, operations ceased on what is now known as the Lucky Cross property during the year 1908, and it has been altogether idle from that time till the beginning of June of the present year. About that time it began to be a desirable piece of property because of the valuable discoveries made on the property of the Swastika Mining Company during the latter part of 1910 and the early part of 1911. About this time, also, some gentlemen from Philadelphia secured control of this abandoned property, and the writer (who had made the discoveries on the Swastika property) was placed in charge of the work of prospecting, with the result that in a very short time two distinct veins, not before explored, were opened up and shown to carry good gold values. The first was

* Manager, The Lucky Cross Mines.

the one already referred to. It is located on Claim No. T. C. 58, and is quite close to the track of the T. & N. O. Railway. The second one is located about 400 feet in a southeasterly direction from the first find; this vein is smaller than the first but is much richer. Eleven samples taken from this one, taken by cutting a groove right across the vein and for a total length of about seventy feet, gave an average assay value of $112 to the ton.

Early in July the Lucky Cross Mines of Swastika, Limited, was formed to take over this property. Prospecting was continued under the same management, with a small crew of men, with the result that at the present time there have been uncovered and prospected to a small extent 34 separate and distinct veins; six of which show visible gold. A few others give fairly good assay values and indicate that they are well worth further prospecting and proving; while several others have simply been cut in the trenches. On these latter nothing has as yet been done in the way of ascertaining their values.

The results spoken of are the work of only two months with a small crew of men, but it easily places this property in the front rank among the properties in this district.

The track of the Temiskaming & Northern Ontario Railway passes through three of the claims of the Lucky Cross Mines, Limited, thus making this property the most easily accessible in the district. The necessary machinery for mining and milling can be delivered within one hundred yards of the site where the shaft will be sunk and which is also a nice mill site for future use.

The first surveyed townsite of Swastika is also a part of this property and will be a considerable source of revenue.

A few lines relating to the course to be followed in developing this property may not be out of place. A shaft will be sunk on Vein No. 16 to the 100-foot level, where a station will be cut and crosscuts driven either way. Eleven veins will be cut in about 400 feet; one of these is about 20 feet wide and shows some visible gold on the surface.

Compressed air will be used for drilling. A six-drill compressor will shortly be installed.

Smelting with Oil Fuel

In July Mr. Thomas Kiddie, metallurgist, of Vancouver, B.C., made a brief report to the Dominion Oil Smelting Co., Ltd., Vancouver, relative to a recent additional test of the use of oil as fuel in smelting copper ore, as follows

"In compliance with your request, I proceeded to Van Anda, Texada Island, accompanied by Mr. Carlsrud, general manager, for the purpose of making a further demonstration with the oil-burning furnace. Two days were there occupied in overhauling water pipes, machinery, furnace engine, blower, and water and oil pumps, all of which were tested before the demonstration was begun.

"The ore mixture smelted consisted of Boundary district ore, iron ore as a flux, and copper slag from a previous operation. The furnace was started at 11 o'clock, a.m., using two burners until it became sufficiently heated, when two more were started. Everything went along satisfactorily and slag began to flow at 12 o'clock, noon. The slag was hot and increased in quantity until it ran a pot of slag in one minute of time up to 2.30 o'clock, p.m., during which time it smelted without trouble or interruption.

"Allowing one hour for the heating up of the furnace—a very conservative allowance—we used 57 gallons of oil in 2.33 hours, and 60 gallons for heating up the furnace, or 217 gallons in all. This gives an average of 14.6 gallons of oil per ton of material smelted, equal to 43.8 cents per ton of ore. The rate of smelting was 110 tons per 24 hours, an increase of more than 100 per cent. over the results obtained during the best previous demonstration.

"I have no hesitation in saying that these conditions can, and will, be much improved upon after certain changes shall have been carried out, so that advantage may be taken of better and more complete combustion of the oil, when the cost of oil consumed per ton of material smelted should approximate 30 to 35 cents per ton of ore. The saving of labour cost at the furnace I estimate at nine cents per ton of ore.

"As a result of this and previous demonstrations I strongly recommend that the furnace be remodelled along the lines already submitted by me to your company, and endorsed by at least two metallurgists of the highest standing in British Columbia."

The company has decided to proceed at once with the remodelling of the furnace, as recommended by Mr. Kiddie.

Ontario's Mineral Production

Returns to the Ontario Bureau of Mines, Parliament Buildings, Toronto, show that the output of the metalliferous mines and works of Ontario for the six months ending June 30th, 1911, was as follows:

	Quantity.	Value.
Gold, ounces	2,276	$ 42,320
Silver, ounces	15,231,969	7,644,200
Copper, tons	4,418	631,827
Nickel, tons	8,418	1,809,759
Iron ore, tons	94,803	239,114
Pig iron, tons	255,303	3,923,593
Cobalt and nickel oxides, pounds	219,584	64,876

Compared with the corresponding period of 1910 the above figures show the following increases:

Gold, ounces	2,276	$ 42,320
Silver, ounces	2,417,142	1,378,670
Iron ore, tons	55,306	126,032
Pig iron, tons	33,585	382,905

and decreases as follows:

Copper, tons	216	28,670
Nickel, tons	921	195,901
Zinc ore, tons	576	5,000

In quantity the shipments from the silver mines amounted to 12,113 tons, of which 7,733 tons were ore and 4,380 tons concentrates. In addition, 1,302,699 oz bullion were sent out. For the first six months of 1910 there was shipped of ore 12,041 tons and 2,763 tons concentrates. There is, therefore, a considerable falling-off so far as shipments are concerned, in actual weight, but a decided gain in value. Taken in connection with the increase in shipments of concentrates, this would indicate that the mines are confining their ore shipments largely to high grade, and putting the

ower qualities through the stamping mills. Gowgan- a sent out 110 tons ore and 2 tons concentrates, and outh Lorrain 216 tons ore, the whole containing 430,- 40 ounces of silver.

The yield of gold is still small, production at Porcu- ine being delayed by the disastrous fires, which de- troyed the plants at the Hollinger and Dome mines.

Granby Company's Hidden Creek Mine

Mr. Jay P. Graves, vice-president and general mana- ger of the Granby Consolidated Minnig, Smelting, and Power Company, Ltd., has returned to Spokane, Wash- ington, from his second visit to the company's Hidden Creek mine at Goose Bay, Observatory Inlet, British Columbia. The Spokesman-Review quotes him as hav- ing said, in part: "The Cabin Bluff ore shoot, the small- er of the two main outcrops on our Hidden Creek pro- perty, contains a fine body of ore. We have drilled five or six holes in this ore shoot; some of these have been drilled 800 feet continuously in ore, and the cores from the lowest parts of the holes, which are about sea-level, give an average assay return of 3 per cent. copper. The last cross-cut through this ore shoot was in ore averaging 6 per cent. copper across 125 feet.

"The tunnel through the Cabin Bluff has been ex- tended to the Mammoth Bluff. It was within 15 or 20 feet of the beginning of the ore shoot in the latter when I left the mine. This is much the larger ore body, and its grade will shortly be demonstrated. So far our operations have indicated that it will average at least 3 to 4 per cent. in copper."

(Note—This property was examined in 1909 by Mr. Herbert Carmichael, Provincial Government Assayer. In his Bulletin No. 1, published in that year, he said, in the course of his description of the property: "Pros- pectors were first attracted by a round-topped hill, about 1,000 feet high, which was more or less covered by a typical 'gossan' or iron cap. Prospecting showed that this gossan was thicker and more strongly marked in some places than others, and attention was specially directed to these points. The first of this work was done on a large exposure of these oxidized ores, which proved to be 5 feet thick. This gossan was cut by a number of trenches which disclosed a body of mixed pyrite and chalcopyrite ore, and this was prospected by four tunnels, aggregating 200 feet. These tunnels developed a large body of ore carrying 4 to 6 per cent. copper, which was called the 'Cabin Bluff,' and is at an altitude of 700 feet.

"About 500 feet back round the hill and 200 feet higher than the 'Cabin Bluff,' another and larger ex- posure of ore was discovered and named the 'Mammoth Bluff.' This has been cleared off to a large extent by surface stripping and shows a height of 300 feet of mixed pyrite and chalcopyrite ore, containing 4.5 to 5 per cent. copper. This ore deposit has been pros- pected by several tunnels, in all 350 feet in length.

"There are several smaller showings on this hill, and these, with the 'Cabin' and 'Mammoth' Bluffs, have been prospected by 2,000 feet of open-cut, beside the tunnels. To tap these ore bodies at depth and form a main working tunnel, a long drift has been started on the hillside 200 feet vertically below the Cabin Bluff, and when the property was visited this drift was in 732 feet. At 480 feet in, the ore seen in the Cabin Bluff above was struck, the tunnel cutting through it, the strike of the ore being N. 10 deg. W., dip 65 deg. W. The thickness of the orebody is estimated at from 25 to 40 feet, running from 4 to 5 per cent. copper. Drifts 70 feet long have been run on either side of the tunnel in ore all the way, the direction of the tunnel being 90 deg. from the strike of the ore.

"Round the hill to the south 265 feet, and at an elevation of 100 feet above, the main tunnel, a drift known as the 'Pyrites tunnel' is being driven to con- nect with a raise from the main tunnel. For the first 100 feet this tunnel runs through loose granular py- rites, made up of small detached iron pyrites crystals similar to those found on the Ecstall pyrites deposit, near the Skeena River. At 100 feet in, solid mixed iron and copper pyrites ore was struck, containing 4 per cent. copper for 10 feet, when a lower-grade iron sulphide ore was met with, and the tunnel is still in this ore at 200 feet from the portal.

"The vertical height between the main tunnel and the top of the Mammoth Bluff deposit is 450 feet, and with the prospecting done it is reasonable to infer that the ore shoot is continuous for this vertical distance. The horizontal boundaries of this orebody have not been clearly defined, but it is probably some 600 feet in length by 20 to 25 feet in thickness, containing 3 to 4 per cent. copper.

"At the Cabin Bluff showing there is a considerable depression in the ground, which appears to have been caused by the oxidizing and dissolving out of the py- rites ore body, and there is a large deposite of hema- tite in a flat of 10 acres south of the ore showings, where this dissolved out ore has been redeposited. Samples of this deposit gave the following assay re- turns: Iron, 60 per cent.; gold, 0.10 oz.; copper, 0.2 per cent.

"The country rock in the vicinity of the ore body is made up of altered argillites or shales, traversed by felsite, diabase and porphyry dikes, these dikes being of later origin than the ore. In some parts of the de- posits there is a vein-filling of quartz, but the main body is composed of solid sulphide ores.")

It should be remembered that the report from which the foregoing extracts have been made was published before the Granby Company became interested in the Hidden Creek property, and consequently previous to the commencement of the large amount of under- ground exploration since done by that company. The information is here quoted, though, with the object of directing attention to the fact that particulars con- cerning the property, obtained by an official of the Provincial Department of Mines, and therefore quite disinterested, and published by the Government two years, indicated the occurrence on the Hidden Creek group of a large body of copper ore of commercial value. Since then the considerable exploration car- ried out by the Granby Company, both by ordinary underground mining and by diamond drill, has de- termined the occurrence here of an immensely larger quantity of ore than was previously known to exist.

Continuing the quotation from the Spokesman-Re- view representative's interview with Mr. Jay P. Graves, the following additional information is given:

"For the last month we have been employing 150 men, and the force is gradually being added to. All the engineering work in connection with the equip- ment of the property has been completed. The right of way for the tramway from the mine to the ore- bunkers on tidewater, a distance of a mile, has been

cleared, as, too, have the sites for the orebunkers and wharves. By September 1st we will have construction work well started on the 400-foot wharf, and on two orebunkers—one, of 4,000 tons capacity, at the mine, and another, of 6,000 tons, at the dock.

"A sawmill, having a capacity of 40,000 feet a day, is in operation, and an electric light plant is being installed in connection with the old water-power. The construction of a dam higher up the creek will shortly be commenced; this dam will give a head of 350 feet and will provide water for the development of 3,500 electrical horsepower for our new plant.

"The head employees of the company are still collecting data that will determine the company's policy with regard to the treatment of its ore. When all the necessary data shall have been obtained, we shall decide whether for the present we shall send the ore to a custom smeltery, or at once proceed to erect our own reduction works. It will also be decided where our plant shall be located, and whether we shall treat only our own ore or do a general custom smelting business as well. We expect to be able to reach a decision on these matters before October 1."

THE HELEN IRON DISTRICT

(Written for the CANADIAN MINING JOURNAL
by W. L. Goodwin.*)

Ontario's iron ore mining, like its gold mining, has had a somewhat chequered experience. From the early days when pig iron was made from the bog ore of Norfolk County down to the present there have been a good many iron deposit sopened up, particularly in eastern Ontario, but the Helen mine has been the only large steady producer. Other deposits have been found too small or too lean to work profitably, or they have run into too much sulphur. The Moose Mountain and Atikokan deposits are large, but it can hardly be said that they are yet on a solid basis as steady producers.

The writer can compare the present state of development of the Helen mine district with its condition in 1902. At that time the Helen was worked on a very large scale by the open pit method. The Josephine, about 10 miles to the northeast, was being prospected also. The output at the Helen was about 500 tons a day. In 1903, under the energetic management of Mr. R. W Seelye, with a much reduced working force, the output was pushed up to 1,000 tons, which has been maintained ever since. Since that date the work has been exclusively underground. The ore hoisted still consists largely of limonite and gothite, but there is a considerable proportion of hematite. The pipes of pyrite sand, so characteristic of the early stages of development of the mine, are still met with. Solid masses of pyrite are occasionally found. But both are so localized that it is comparatively easy to mine a product low in sulphur. These pipes of pyrite are very curious. When they are broken into the sand runs out like so much water. The Helen ore is easy to mine and it works well in the furnace. Mr. Haselbring, the present general superintendent, tells me that the output just now is about 1,100 tons a day, and that most of it is used in the furnaces at Sault Ste. Marie. The ore is hoisted by two skips, crushed with a gyratory crusher, loaded directly into the ore cars for transportation to Michipicoten Harbour (12 miles), where the cars are run out on the loading dock and dumped into the ore boats. The shaft has been sunk 750 feet, and drifting has been carried on down to the 700 foot level. Early in the summer the timbers began to show signs of a cave. The progress of this was carefully watched, and in July the men were all ordered up to the surface, soon after which the cave occurred, bringing down a mass estimated at 350,000 tons—a year's supply of ore, requiring only occasional block-holing to make it ready for mucking. At one place a solid block of ore came down, just filling the drift—so neatly that the rails seem to run into unbroken ore.

When the writer was there in 1902 Boyer Lake, just west of the workings, was being pumped out, to dispose of the water, which was becoming troublesome and to allow the bed of the lake to be prospected. Drifting under the bed of the lake has not revealed any large bodies of ofe. A launder has been run around the south side of the mine and continued along the shore of Boyer Lake to Sayers Lake just below. This takes care of the mine water and also of a large part of the drainage from the hills on that side. Since this was done, it has been found unnecessary to continue the pumping of Boyer Lake. The mine pump takes care of it all.

The mine buildings are noteworthy for the evident care taken to give the men comfortable, safe, and sanitary conditions. The writer accompanied Mr. Seelye, the general manager, throughout an inspection of the camp. The minute, unsparing character of that inspection accounts in part for the admirable discipline of the camp. In 1902 "blind pigs" and other undesirable camp features were much in evidence in the district. These have completely disappeared and one hears startling tales of the drastic measures used to abolish them. With these features have disappeared much dirt, waste, and general disorder, too evident. tion of sand, common sense, and study of the best interests of the mine, managers may rid themselves of a visitor in the earlier days. By a judicious combination such demoralizing influences, which so seriously interfere with discipline and efficiency.

Notable features of the Helen mine to-day are the brightness and comfort of the dining and sleeping camps. With a good water supply laid on from a lake on the top of the hill east of the mine, baths and wash hand-basins are supplied for the men. Instead of large dormitories with tiers of bunks, one sees separate rooms, securing something of the privacy of the home. Electric lights are used everywhere, both power and light being supplied by the water power developed at the falls of the Michipicoten River 11 miles away. There is also a good drainage system. The largely increased output with a much smaller force of men (now about 200), is in part explained by the general briskness of the camp which accompanies this careful attention to comfort and sanitation. Many of the mar-

*Director School of Mining, Kingston, Ont.

ed men, including English, Finns, and Italians, have ought in their families, and there are enough child- n of school age to keep one teacher busy. It was teresting to see the tow-headed Finns and dark Ital- n children playing together, and all talking good anadian English.

The Helen iron mine is then undoubtedly the largest ad most important iron ore producer in Canada at resent. There is still a very large known body of ore there to be taken out, and the mine has possibilities in depth. But a most interesting new development of the district is found at the Magpie mine.

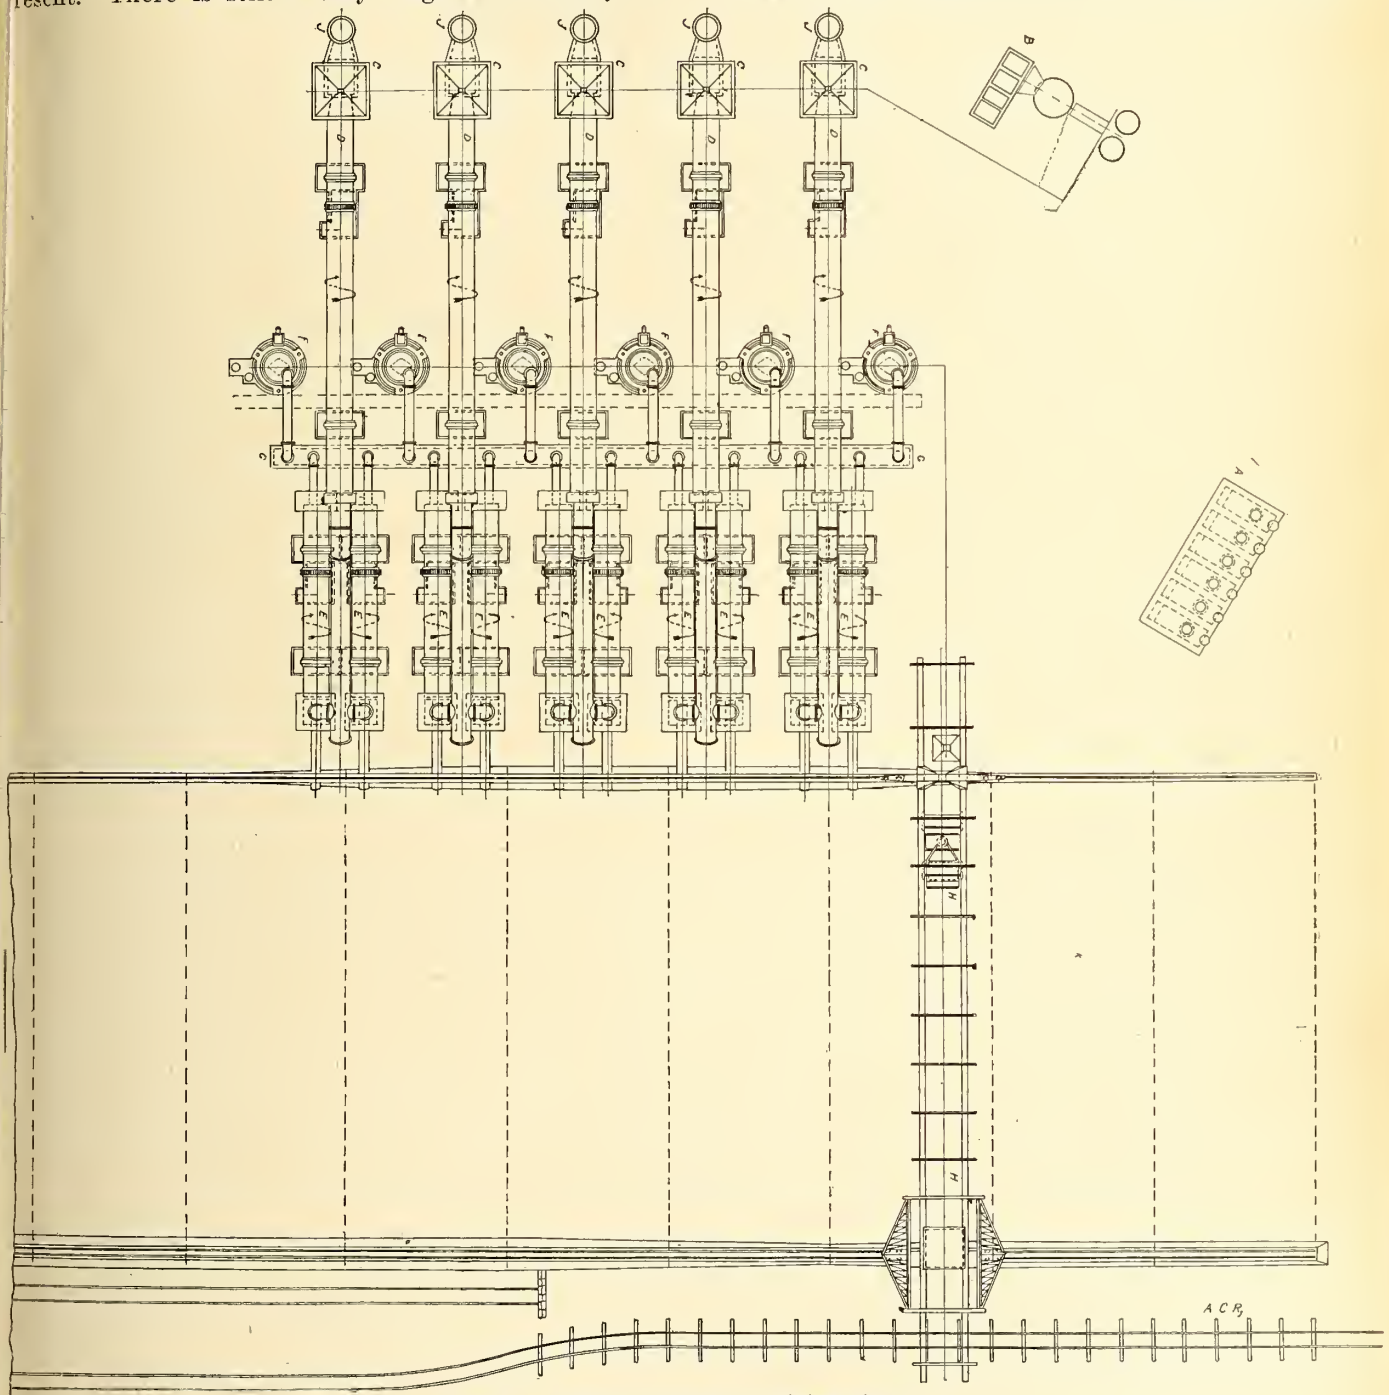


Fig. 1. Plan of Yard and Calcining Plant.

The Magpie Mine.

The character of the Helen iron formation has been made familiar by the reports of Dr. A. P. Coleman in the Ontario Bureau of Mines Reports.* (a) The most interesting feature of the Helen formation is the siderite, ankerite, etc., more or less banded with chert and sandstone, an deontaining more or less iron pyrite. It has been conjectured that the Helen mine had its origin by a process of leaching of the carbonate material and its concentration by precipitation to the bottom of a lake after ovidation to limonite. This process can be seen going on now in the remains of Boyer Lake. The plentiful occurrence of iron pyrite in these rocks suggests another possible origin. It is quite likely that both the carbonate and the pyrite have contributed to the process. (b) Those visiting the Helen mine can see the principal features of the formation beautifully shown in the rock cuts made by the railway as it passes along Sayers Lake and crosses the very narrow ridge which separates Sayers from Boyer Lake. (c)

About twelve miles north of the Helen mine, at a point near the Magpie River, the siderite is so concentrated as to constitute a workable iron ore. Here the Mines Department of the Lake Superior Corporation have proved by diamond drilling an ore deposit 000 feet long, and at least 650 feet in depth. The width where a shaft is sunk and the deposit cross-cut, 59 feet. A conservative estimate made from the drill log puts the average width at 30 feet. Some 2,000 feet of drilling were done. In parts of this deposit the ore passes into magnetite.

The fresh siderite is compact and quite white, but when exposed to the air soon weathers to the characteristic rust colour of limonite. This is well seen at Iron Knob, a jagged peak very conspicuous towards the east end of the range. In composition the ore will average about as follows:

Iron, 40 per cent.
Carbon dioxide, 18 to 20 per cent.
Lime, 7 per cent.
Magnesia, 5 per cent.
Manganese, 2 per cent.
Alumina, 1 per cent.
Silica, 8 per cent.
Phosphorus, under 0.02 per cent.
Sulphur, under 4 per cent.

For comparison, the Helen ore analysis for 1910 is given herewith:

	Dried.
Iron	57.77
Lime	0.23
Magnesia	0.14
Manganese	0.165
Alumina	.880
Silica	4.40
Phos.	0.127
Sulph.	0.136
Loss by ignition	10.40

The probabilities are that the ore will carry about two per cent. of sulphur, which occurs in the form of iron pyrite more or less disseminated through the ore, in marked contrast with the segregated masses of pyrite at the Helen mine.

The high percentage of sulphur is, of course, prohibitive to the use of the raw ore, but fortunately it can be completely removed by roasting, leaving the ore of excellent Bessemer quality. The ore is distinctly basic in character, although the silica and alumina present will balance more than half of the lime and magnesia. The high percentage of manganese also increases the value of the ore.

By a long series of large scale experiments, using up some 200 tons of ore, it has been established that it can be roasted sweet, the sulphur being reduced as low as is desired, even down to a vanishing quantity. There is no difficulty in reducing it to 0.10 per cent., and it is not necessary to bring it down below this. The ore at the same time loses about 20 per cent. in weight, with a rise in the iron content to 50 per cent. or over, mostly in the ferrous condition. After a careful reading of the reports made on these experiments, which were carried out under the superintendence of Mr. Seelye, the writer is convinced that the feasibility of the roasting process has been established beyond a peradventure.

The roasting plant is now being constructed under the superintendence of Mr. Wm. Melville, metallurgist, Detroit, and Mr. R. E. Clisdale, mech. engineer, Toronto. Through the kindness of Mr. Seelye I am able to give a general plan of the roasting plant and accessories and a short description of the process. The ore is crushed to one and a half inch. On account of its compact nature it crushes with very little fines. From the crushers it is conveyed to hoppers, which feed it to the calcining furnaces, of which five are being installed at present. It has been found advantageous to drive off the carbon-dioxide by a preliminary calcination, for two reasons. The waste heat of the roasting furnaces can be utilized for this purpose, and the ore is left in a porous condition by the escape of the carbon-dioxide, so that the subsequent oxidation in the roasting furnaces is unusually effective. This arrangement has another advantage. It makes possible the maintenance of an even high temperature throughout the length of the roasting furnaces. The experimental work established this as the most favourable condition for the complete elimination of the sulphur.

The calciners are rotating tube furnaces, of the cement furnace type, 125 feet long and 8 feet in diameter. These are heated by the waste gases from the roasters, the gases being carried by pipes from the bottom of the roaster and entering at the bottom of the calciners. The gas therefore travels against the direction of movement of the ore. The temperature of the lower end of the furnace reaches about 800 degrees Centigrade. There is no considerable reduction of the sulphur contents.

The roasters are built in pairs, each one of a pair revolving in a contrary direction to the other. Each pair receives the ore from one calciner. They are 60 feet long and 5 feet in diameter. The temperature is maintained at 1,100 degrees Centigrade by producer gas, which is introduced with air at the upper end of the furnaces, so that the flame travels with the ore. In this way it is possible to maintain a long flame and very even temperature throughout the tube. The temperature must not rise above 1,100 degrees, as sintering will then take place. There are six of these producers, one for each pair of roasters and one in reserve. The fuel used is soft coal. The producers are of a special construction and are being made by the Chapman Engineering Works, Dundas. Each producer is in two sections joined by a water seal. The sections revolve at different rates so as to give constant stirring of the fuel. This prevents blow holes and insures a constant supply of gas of uniform composition, both points being essential to the success of the process. The output from these furnaces will depend, of course, on the rate at which they are revolved. This is determined by the percentage of sulphur, a higher percentage requiring a slower rate in order to secure the desired elimination of sulphur. On an average it is estimated that the output will be 15 tons an hour per unit. This will give a total production of about 1,500 tons a day for the five units at present being installed.

The plant is designed so as to give very perfect control of the movement of the ore, of the flow and composition of the producer gas, and of the draught. The latter is controlled by a fan which gives a pressure equal to 16 inches of water. In the experimental work the waste gases after leaving the calciners were found to contain 16 per cent. of oxygen. If the gases from the roasters do not give the required temperature in the calciners, this can be secured by the introduction of a little producer gas.

From the roasters the ore is passed into the storage bins, and is there handled by an electric crane, the bridge having more play than usual so as to reach several bins without being moved along the traek. The finished ore is in hard nodules, very easily handled by the elam-shell, hard enough to bear transportation and furnace burden, but so porous that it must work particularly well in the furnaee.

The Magpie mine is reached by a branch of the Algoma Central Railway built from the Josephine braneh at a point about 8 miles north of the Helen mine junetion. The whole distanee from the Magpie mine to Miehipieoten Harbour is 28 miles, with grades in favour of the loaded movement. In addition to this summer route there are, or will be, two possible winter routes, as the Algoma Central Railway is being built northward to connect with the main line of the C. P. R. at Hobon. The A. C. R. is now being eonstrueted from the "Soo" northward to the Helen mine distriet. The greater part of this line is already in operation.

The mine buildings for the Magpie are being erected with the same attention to solidity, comfort, and health as exemplified at the Helen. The water supply is being pumped from the Magpie River. The drainage will be piped into Camp Lake, which is a mile and a half below the intake of the supply station. Power will be obtained from Steep Hill fall on the Magpie River, which is 1½ mile from the mine. An auxiliary steam plant is being built at the mine.

As the amount of ore blocked out by the diamond drilling is calculated to be something like twenty million tons, it is quite evident that we have here an important addition to our known iron ore resourees. The estimated eost of the roasting proeess is between 35 eents and 40 eents a ton on the production, not a heavy addition to the eost eonsidering the charaeter of the ore turned out.

(a) Professor Coleman (Bureau of Mines Report, 1901, p. 155) proposed the following classification of the rocks.

Laurentian—Gneisses and Granites.

Upper Huronian—Acid eruptives, Basic eruptives, Dore conglomerates.

Lower Huronian—Eleanor slates, Helen iron formation, Wawa Tuffs, Gros Cap Greenstones.

This places the Helen Iron Formation in the Lower Huronian, which has been so productive of minerals in other parts of Ontario.

(b) That this is the case is perhaps shown by the occurrence, in and near the ore, of masses of losse silicious saud corresponding in structure to the bands of sandstone in the siderite, and also of quantities of loose pyrite sand. The silicious sand was doubtless formed by the disintegration of the siderite formation with the solution and removal of the carbonate, leaving the insoluble silica in place, or perhaps allowing it to be carried by the streams of water and deposited near the place of deposition of the ore. If, in addition to carbonic acid the eirculating waters carried oxygen, the pyrite would also be attacked and its iron carried away in solution as ferrous sulphate. The more perfect crystals and compact fragments of pyrite would resist this attack longest, and form the pyrite sand so characteristic of the Helen ore body.

(c) Analysis of surface specimens of the siderite formation and of drill cores from a depth of about 150 feet show up to 36 per cent. iron. It is obvious that if such a formation were found uniform enough, in sufficient quantity, and in other respects favourable in composition, it might constitute a workable iron ore. This was pointed out by Professor Coleman in the Report of the Bureau of Mines for 1901, p. 193:

"Analyses of specimens from the hilltop (east of the mine) and from the outlet of Boyer Lake have been made by myself, No. 1 being from the hill, and No. 2 from the west end of the lake, and the results are as follows:

	No. 1.	No. 2.
Insoluble	4.38	14.16
Carbonate of iron	78.57	74.17
Carbonate of magnesia	12.84	8.35
Carbonate of lime	4.09	0.99
Alumina	trace	trace
	99.88	98.67
Specific gravity	3.681	3.57
Iron	37.71	35.)

"The insoluble residue consists mainly of very fine particles of silica. . . . . No account was taken of the iron pyrite, which would have given a considerable amount of sulph, perhaps even one or two per cent. . . . But for the pyrit, the rock from the hill would be accounted a fair ore of ir in some parts of Europe; and if this siderite were roasted would yield a product having 56.57 per cent. if iron, not mo than 7 per cent. below the iron contents of the ore from t mine; and, if the sulphur were all roasted out, would form very fair ore, having 9.17 per cent. of magnesia and 3.14 p cent. of lime to serve as fluxes for 6.56 per cent. of insolub material, mainly silica."

It thus became a question of quantity of siderite, and of feasible proeess for roasting. The percentage of silica is course a factor, as the value of the ore is increased by an e cess of limo and magnesia over that required for slagging t silica and alumina. In another place Professor Coleman not the presence of something like 2 per cent. of manganese the siderite, and points out that it has not been carried dow in the precipitation of the limonite ore.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

The Geological Survey has recently issued a Memoir on the clay and shale deposits of Nova Scotia and a part of New Brunswick. The author is Heinrich Ries, who was assisted in his investigations by Joseph Keele. Particular attention was paid to the shales and clays which are so plentiful in the Carboniferous of Cape Breton Island, and the Memoir contains much interesting reading for these interested in local industries, and incidentally corrects some erroneous impressio which are abroad.

In view of the importance of the iron and steel industry i Nova Scotia it is unfortunate that there does not appear to b any deposit of true fireclay in the province, and there is ge erally a decided lack of refractory material. An examinatio was made of a so-called fireclay deposit on Coxheath Mountai near Sydney, which proved to be a light-coloured felsite. B crushing the felsite and usiug a bond of clay it would be po sible to make a hard brick, but not a firebrick. An interestin

Note—Memoir No. 16-E, Geological Survey Branch, 1911.

pocket of white residual clay was found in a depression near the ridge of the mountain, which the authors think may have caped glacial erosion, but the deposit is too small to be of onomic value.

There appears to be an abundance of suitable material in ape Breton for the manufacture of ordinary red and buff rick, particularly in the neighbourhood of Glace Bay and dney, and near the town of Inverness.

An interesting deposit was noted in the Shubenacadie and usquodoboit valleys, which is evideutly of pre-glacial origin, it underlies the drift. The authors tentatively class it as esozoic. This deposit contains material which is classed fireclay and could be used for the manufacture of pressed rick, terra cotta, and stove linings. This deposit the authors nsider could be profitably opened up.

There are clays in the Annapolis Valley which could be used r making cheap art pottery and terra cotta tiles, and some the smoother clays in the Anapolis Valley and near Inver-ss could be used for the manufacture of stoneware.

The authors believe that there is room for development in e Nova Scotia industry, but the product resulting from it will ave to be marketer mainly outside of the Province. There e few pressed brick works between Ontario and Nova Scotia, d this territory should afford a good field.

Although Nova Scotia appears to be lacking in deposits of e residual clays suitable for pottery manufacture, and there no great quantity of really refractory manufacture, yet it quite evident that there is no lack of material for the manu-cture of ordinary brick, and some of the better grades of e clay-workers' art, such as terra cotta tiles, stoneware, ain tiles and pipes, and coarse pottery. The Memoir is a ry valuable one, and should be obtained by those interested the clay industry.

It may be noted that a large business is now being done in dney in cement bricks made from the Dominion Iron & eel Compauy's slag.

ominion Coal Output.

The output of the Dominion Coal Company's Glace Bay col-eries for August exceeded any previous monthly production. he figures are as under:

No. 1	52,770
No. 2	71,400
No. 3	17,720
No. 4	38,740
No. 5	28,540
No. 6	26,680
No. 7	18,120
No. 8	17,430
No. 9	39,470
No. 10	18,100
No. 12	27,590
No. 14	24,380
No. 15	3,920
No. 16	1,170
No. 21	1,500
	387,530

This output is 17,000 tons larger than the best previous nonth in the company's history. No. 2 Colliery, No. 6, No. 10, nd all the Lingan mines from Nos. 12 to 16, established new ecords.

The output for the eight months ending August this year is pproximately 2,650,000 tons, comparing with 2,259,000 tons in he same period of last year. The best previous production for his period in any previous year was 2,610,000 tons, in 1908, so that the Coal Company's output to date is 40,000 tons larger than in any former year.

The output from the Springhill Collieries for August was 30,164 tons, which is the largest production for over two years.

The output of the Glace Bay mines during August was a really remarkable one, cousidering that the 12th was observed as a geueral holiday, being the annual picnic of the P. W. A. This occasioned a decrease of 20,000 tons in the production, so that the rate of output was easily 400,000 tons for the month. To those who know the large expenditure which has been made on these collieries during the past eight years it is not a matter for surprise that the property is uow showing of what it is capable. Since 1904 the Coal Company have developed No. 6 Colliery on the Phalen seam, and No. 10 Colliery on the Emery seam, on the Glace Bay side; and have on the Lingan side two new collieries in full operation, and two in course of developmeut. In additiou to this some of the older mines, such as No. 5 (Reserve), and No. 7 (Hub), have been practically remodelled. In this period also a large part of the mine machinery has beeu changed over from steam drive to electricity, and the large portion of the colliery pumping, ventilating, and screening plauts is now operated by electric power.

Extensive prospecting operations are being undertaken by the Dominion Coal Company in the Cumberland coal field with a view to the location of new winnings near the Springhill Collieries. Diamond drill-holes are being put down to test the measures. The correlation of the coutorted seams of the Cumberland basin is not by any means so simple a matter as the correlation of the seams in the less disturbed areas at Glace Bay, and the prospecting at Springhill will afford some interesting work.

ONTARIO.

COBALT, GOWGANDA, AND SOUTH LORRAIN.

Ore shipments from Cobalt for the week ending August 25 established a record for 1911, 748.22 tons being sent out, including 15 cars of high grade and 7 cars of low, from thirteen mines. During the week ending September 1, three cars less than in the precediug week were shipped, 15 of high grade and 4 of low, from eleven mines. The shipments totalled 1,167,029 pounds, or 583.51 tons. During this period of two weeks, two mines shipped bullion. The Crowu Reserve sent 11 bars, worth $8,000, to London, England, and three shipments were made by the Nipissing inside five days. These consignments were of 15 bars, worth $8,738.60, and the other two, totalling 114 bars, valued at $63,483, which, for a week, is a record for the camp.

Dividend No. 19 of the Crown Reserve has been declared for August payable on September 15. It is at the regular monthly rate of 2 per cent. with a bonus of 3 per cent. Since 1908 the Crown Reserve has paid back to shareholdedrs 195 per cent., representiug disbursements totalling well over the $3,000,000 mark. On August 22 this mine shipped a car of 30 tons to the government of Saxony. The ore was over 5,000-ounce stuff. Nine large machines are working undergrouud and preparations are practically completed for further sinking on the Carson, or main, vein. The winze is uow down over 160 feet below the 300-foot level and a head frame and cage are being placed in position. This winze will be sunk 150 feet, making the deepest working on the property 610 feet.

Frank L. Culver, president of the Beaver, when iu Cobalt recently, said it was the compauy's intention to sink the main shaft another 100 feet below the 400-foot level. Shortly before the president's visit the No. 5 veiu was struck at the 400-foot level of the shaft, and drifting has been started northward along the ore body.

This week saw the openiug of the concentrator at the Cobalt Lake mine. It has a capacity of 75 tons a day at present but it is expected that this will be increased to 100

tons daily before long. Mining operations are being carried on in shafts Nos. 4 and 6. The former is being worked at the 170-foot level where the old vein is being opened by drifting. At No. 6 shaft work is progressing at the 285-foot level. Crosscuts will be run from a certain point at this depth and raises cut to the shaft, to connect at the 195-foot level. A new vein carrying some native silver was discovered a few days ago and a drift has been started to open it up and determine the values.

At the 200-foot level of the Coniagas a spectacular slab of silver 34 inches by 18½ inches and over an inch thick was taken out last week. The find was made in the drift on vein No. 12, one that is carrying high silver values. The vein is little more than 3 inches wide, but it is a steady producer of high grade.

Operations on "H" vein at the Trethewey on the first level between Nos. 1 and 2 shafts disclosed some high grade ore that had been overlooked when the vein was originally worked. To date over 60 feet of good ore has been opened up and in the wall rock there is plenty of milling ore. The mill is running steadily at a capacity of 100 tons a day, and nothing but high grade is being shipped.

At the 100-foot level of the Cobalt Townsite mine another vein has been encountered which gives promise of producing much good ore. This vein was found in a crosscut about 300 feet west of the shaft. Five drills are working underground. A contract with the Northern Customs Concentrator calls for 50 tons of ore daily. This ore is being trammed to the concentrator and comes from underground work only.

Developments at the Belleville, in South Lorrain, have been of the most satisfactory nature during the past few weeks, and some spectacular ore bodies have been opened up. The force of working men is being increased and shipments of high grade ore are being made regularly.

In crosscutting westward at the 575-foot level of the Temiskaming to make connections with the main shaft, a large vein of high grade ore was cut. Unless it has faulted from an upper level this is an entirely new ore body. The vein is from one foot to 2½ feet wide and in places the values are exceptionally high.

Work at the Millerett and the O'Brien mines in Gowganda is going on quietly but effectively. The latter mine recently shipped a 19-ton car of ore that netted the company over $38,000.

Porcupine, Swastika, and Cripple Creek.

Nothing has so increased interest in the Cripple Creek district as the recent transfer of the Jowsey-Wood claims in Carscallen township to A. D. Miles, consulting engineer for the Canadian Copper Company. The Jowsey-Wood claims are situated on the 3-mile post on the base line of Carscallen, two of them on the boundary line between that township and Denton. A big quartz dyke holding rich values with spectacular free gold showings runs through the entire group of claims. This deal, following so closely the transfer of the McAulay-Brydge claims for half a million dollars gives great prominence to the district west of the Mattagami.

West Shining Tree, 40 miles north of Gowganda, is the latest goal of gold seekers, and a rush of no small proportions resulted from the finds of Alfred Gosselin, who, so far, has staked the best claims yet prospected. The formation in the new district resembles greatly that found in the Porcupine area and veins uncovered run from mere stringers to 15 and 20 feet in width. On Gosselin's main discovery free gold shows in several places and assays taken from a number of veins go as high as $25.

A gang of about 20 men is busy at the Homestead m[ine], Swastika, stripping, trenching, and at other surface work. A shaft has been started on No. 3 vein, and it will be made [the] main working shaft, the first station to be at 100 feet. A [new] vein at least 10 feet in width was found a few days a[go], carrying excellent values.

A new shot drill has been taken out to the Porcupine [and] Hudson's Bay gold mines. It is a Rand-Davis-Calyx drill w[ith] a 6¼-inch core, the largest in operation in the camp. M[uch] surface work is being done and a report of two promin[ent] English engineers, whose names are withheld, will be iss[ued] shortly. All buildings destroyed in the fire have been rebu[ilt].

What is considered by some engineers to be one of the m[ost] spectacular showings ever found in any camp is the rich v[ein] uncovered on the eastern portion of the big Dome prope[rty] recently. While trenching north and south a beautiful f[ree] gold showing was uncovered on a vein running east and w[est]. This vein was then uncovered east and west for 72 feet a[nd] eight distinct spectacular showings were disclosed. Offici[als] of the company refused to express any opinion of the val[ues] carried. The show spot of the vein is a patch of almost s[olid] gold 2½ inches by 15 inches. In each case the gold appea[rs] in slabs of schist in the quartz vein which is 18 feet to [20] feet in width.

Work at the West Dome is as yet confined entirely to [the] reconstruction of camp buildings and the replacing of equ[ip]ment. A model town is being laid out with substantial str[uc]tures, a modern system of sanitation and every protect[ion] against fire. Pure water is procured from an artesian well [to] a depth of 170 feet.

Motors and transformers have been ordered for the Pl[a]aurum Mines, and a 10-drill compressor will be delivered in [the] course of a few weeks. A 6 x 8 hoist is now on the grou[nd]. A shaft is being sunk on the Jupiter vein, 200 feet from the li[ne] and another shaft on one of the four veins opened up in [the] corner between the Bewick-Moreing, Platt Vet, and Pe[arl] Lake properties.

A new strike at 90 feet was made on the Pearl Lake p[ro]perty last week, in "A" shaft, free gold appearing in seve[ral] places. In the other shaft some free gold was found at 1[00] feet. At 400 feet a core drill brought up good looking st[uff] that assayed $18.25. Machinery ordered and shipped about [the] end of July has not yet arrived, but is expected at any da[y]. It includes a 12-drill compressor and two stamps which will [be] used for testing purposes.

Two new veins have been found on the north Holling[er] lot, on of them, from 2 to 9 feet wide, being uncovered f[or] 350 feet. Delay in the arrival of machinery has hindered d[e]velopment work and it will be three months yet before t[he] motor ordered can be procured.

Somewhat less spectacular than the Dome showing was th[at] of the North Dome uncovered about the same time. At seve[ral] points on the property rich surface showings were found a[nd] at a depth of 20 feet at one point values were found to [be] most consistent, running entirely across the vein, which was [20] feet wide there. Mr. P. Kirkegaard said there was no pa[y] streak in the vein, it was all paystreak.

It is reported on the best of authority that the Internation[al] Nickel Company has acquired the Porcupine Imperial proper[ty] consisting of three claims near the Dome. The price cannot [be] learned. Several rich finds have been made on the Imperia[l] the latest being last week, when a free gold showing was di[s]covered on the northwest corner of the property. It is co[n]sidered the fourth best showing in the camp. As no deni[al] of the report of this transaction has yet been made, it is bein[g]

ccepted as fact. The deal is an important one and work n the Imperial, it is nnderstood, will be pushed at once to the 00-foot level.

[Editor's Note.—Onr correspondent's last item has been uthoritatively denied.]

BRITISH COLUMBIA.

A matter that is being seriously disenssed by a number of well-wishers of the mining industry of British Colnmbia, is the gross exaggeration and misrepresentation freqnently characterizing both promotion advertisements, in connection with so-called mining companies, and newspaper descriptions of mining properties. The earnest desire to prevent the continued publication of misleading and nntrue statements by reckless or unprincipled company promoters and by other parasites on the miniug industry, whose chief effort appears to be to induce the public to put money into their schemes, is finding expression in enquiry as to the best means to adopt to bring about the punishment of those guilty of trading on the gullibility or ignorance of their victims, and it is not nnlikely that some action will be taken ere long, even if it be only to urge the provincial government to ask the local legislature to enact a law to meet the case if it be found that existing laws do not provide for the effective punishment of those whose nefarions operations are felt to be both harmful to the legitimate promotion of companies to engage in mining, and to the mining industry itself. The attention of the provincial Attorney-General's Department has been called to two or three glaring cases, so it is hoped some means may soon be adopted to check the reprehensible practice of pnblishing grossly untrue statements relative to mining properties.

General.—Among the items of mining news published lately are the following, which are given without attempt to classify nder district headings: It is stated that a contract has been et for hauling 1,000 tons of ore from the Utica mine to the Kaslo & Slocan Railway. Work is to be resumed at the Deep Nine, Whitewater, at which important deep-level development has already been done. A spur is being constructed dfrom the Canadian Pacific Railway at Three Forks, Slocan, to near Bear Lake, to provide railway transportation facilities for the Lucky Jim, Rambler-Cariboo, and other mines. A provisional liquidator has been appointed for the Yankee Girl Mining Company, which for two or three years was operating in Ymir camp, Nelson mining division, and which shipped to the smeltery at Trail a considerable qnantity of ore containing low value, chiefly in gold. There continues to be much activity in Sheep Creek camp; good reports are being pnblished from time to time concerning several gold mines, namely, the Queen, Mother Lode, Nugget, Kootenay Belle, Summit, and others. Rossland mines are maintaining their ontpnt of ore, in largest measnre from the Centre Star group and next from the Le Roi No. 2; the Blue Bird, in the south belt of this camp, is stated to be about to regularly ship galena ore. The excitement so foolishly worked up at Nelson concerning the finding of small quantities of metals of the platinum group in gold-quartz ore from the Granite-Poorman mines, fortunately has been squelched before much harm could be done. The Granby Company has closed its copper mines at Phoenix and smelting works at Grand Forks, pending a resumption of coke-making at the Crow's Nest Pass Coal Company's ovens; the British Columbia Copper Company continues to import coke from Pennsylvania, so as to keep its copper furnaces in blast. The latter company has resumed work at the Emma mine, in Boundary district, an arrangement having been made with the other co-owners that will admit of the mine being worked, which was not practicable during several years while the joint owners failed to agree in regard to terms and conditions under which work should be carried on. It is reported that New York capitalists largely interested in the B. C. Coper Company, have arranged to prospect the Voigt gronp of claims, in Similkameen district (a description of which large property was printed in the Canadian Mining Journal of August 1), under a bond with right to purchase. The Princeton Coal and Land Company is stated to be mining about 100 tons of coal daily; the putting in of necessary coal-cleaning plant is reported to have been authorized by the directors in England, so the outlook for the mine is thereby much improved. Development of coal properties in Nicola Valley district is being actively prosecuted. The Nicola Valley Coal and Coke Company is adding plant and machinery and doing underground work, both adit-driving and diamond drilling, the whole involving a total outlay of $95,000 to $100,000. The Big Copper mine, in Boundary district, which had been idle several years, is being worked under a lease. The concentrating mill, aerial tramway, compressor plant, air line, and water flume for the Standard mine, Slocan Lake, are all about completed.

Slocan.—Much more interest is taken in Slocan district mines by residents in the city of Spokane, Washington, than in the coast cities of British Columbia. The headquarters of the respective managements of several of the more prominent mines are in the former city, and, too, less time is occupied in travelling between Spokanes and the mines than between the coast cities and Slocan. It follows, therefore, that more recent information concerning Slocan mines is obtainable in Spokane than is usually the case in Vancouver or Victoria. Accordingly, the Spokesman-Review, a widely circulated daily newspaper printed in Spokane, publishes more particulars of mining operations at some of the Slocan mines than do the British Columbia coast daily newspapers. Occasionally acknowledgment is made of the fact that Kootenay mining districts contribute substantially to the prosperity of Spokane, as was done on Angust 27, on which date the following was included in the Spokesman-Review's periodical survey of mining, written by Mr. H. W. C. Jackson, who several years ago was editor of the Rossland Miner, aud secretary of the Associated Boards of Trade of Eastern British Columbia.

"There has been a notable increase in public interest both in mining investment and development enterprises during the last month in this city. This has been reflected to some extent by the transactions on the Spokane Stock Exchange, where material advances in price have been recorded in Lucky Jim, Rambler-Cariboo, and other mining stocks. On the curb dealings have been quite heavy in the shares of the Rambler-Cariboo Extension, and McAllister Mines Company, both of which are new development enterprises. . . . Old citizens of Spokane will remember that at various times in the city's history, when business was dull and things apparently at a standstill, new life was injected into the community by the activities of tributary mining camps. The Coeur d'Alenes three different times have contributed largely to a return or increase in the prosperity of the city. The Slocan, Rossland, and Boundary districts of British Columbia and the camp of Republic each has helped in the same way on at least one notable occasion. At none of these crises in the city's history, when mining rescued the community from business depression, were conditions so good in tributary mining camps as they are at present. Never before had so much new wealth been put into sight and rendered available for the employment of labour and remuneration of capital, yet little benefit has so far been derived from recent developments because capital has been indifferent and failed to take advantage of the opportunities offered. . . . The Slocan country has come to the front with a class of producers of much larger calibre than that district has heretofore been credited with. The Standard and Rambler-Cariboo silver-lead mines, and the Lucky Jim zinc mine, are

admitted to be very large tonnage propositions, at the same time that their product is recognized as being of unusually high grade. The Van-Roi is already producing on a large scale, and the Slocan Star, Utica, and other properties soon will be.''

Mr. Jackson did not exhaust the list by any means, but he wrote sufficient to direct attention to the fact that the outlook for mining in the Slocan district is distinctly satisfactory so far as concerns the producing capacity of a number of mines. The chief encouraging feature is that there is now more activity in mining in the district than in several past years, and that it is gradually extending. There does not appear to be room for doubt that there will be a substantial increase in the quantities of commercial metals—silver, lead, zinc, and a little lode gold—that will be taken from Slocan mines in the near future, in some measure this year and to a greater degree in following years.

Coast.—Seldom has mention been made in coast newspapers during recent months of the operations of the Britannia Company, which is employing a comparatively large number of men at its copper mines, situated near Howe Sound, in New Westminster mining division. It is understood, nevertheless, that the prospects of this large property are better now than for several years and that, consequently, further development on a large scale may be looked for. Metal mining in Texada Island is not as important just now as it was some time since, yet work is being continued in several mines. On Vancouver Island there is practically no productive metal mining at present; on the other hand, coal mining is flourishing, with operations expanding and production giving promise of proving larger than ever before. In Portland Canal district, two mines shipping, namely the Portland Canal, which is sending concentrates, containing value in gold, silver, and lead, and the Red Cliff, in which a body of copper-gold ore is being developed. Both mines are shipping to the Tyee Copper Company's smeltery at Ladysmith, Vancouver Island. The operations of the Granby Company at the Hidden Creek mine, Observatory Inlet, are narrated in a separate contribution the Canadian Mining Journal. Prospecting mineral claims the Skeena country—both silver-lead in the vicinity of Hazton, and coal in other parts of the district—is in progress. Queen Charlotte Islands some metalliferous claims are being developed, and drilling for oil is also being done, but the chief interest in that part of the province is in prospecting coal measures occurring on Graham Island of the group. Little information comes from Atlin, but on several comparatively large hydarulic placer-gold mines, full advantage is being taken of the open season, and the expectation is the quantity of gold recovered this year will compare favourably with the yield of any of several recent years. In various other parts of the Coast district prospecting is being done, but as a rule there is not any production on a commercial scale.

GENERAL MINING NEWS.

NOVA SCOTIA.

Sydney, Sept. 1.—President Plummer, General Manager Butler, and Assistant General Manager McDougall, of the Dominion Coal Company, left last night for Wallace, N.S. The company proposes building shipping piers at Wallace or Pugwash for their output from the Springhill mines, which is now shipped from Parrsboro.

Mr. Plummer said last night that a choice between the two ports had not been made as yet. The adoption of a new port, said Mr. Plummer, would be a sequel to an increased output of coal from Springhill.

This is a striking indication that the Coal Company is not very much afraid of reciprocity decreasing its market.

Dominion Steel plant had a good month in all its departments, open hearth turned out over 27,000 tons. Its record was 28,000tons until two months ago, when a mark of 31,000 tons was reached. The Rail plant turned out 15,000 tons during August.

Yesterday the Dominion Coal Company hoisted 16,689 tons of coal. This is the biggest day's outpnt in the history of the company. The output for the month of August, which closed to-day, will be approximately 387,000 tons. This also is a new record, the biggest previous month's output being that of July, which was 16,000 tons less.

The company has also a third record to announce to-dday, the output for the eight months to the last of August being 2,649,000 tons, or 40,000 tons better than the output for the same period in 1908, the best previous year.

Had the month not been broken with an idle day the output would have reached the 40,000; as it was the month's production was at that rate.

The month's output at the company's mines at Springhill was 30,000 tons, the best month's production in two years. If the Springhill output is included the company's total for the month will amount to 417,000 tons.

ONTARIO.

Cobalt.—While cross-cutting west to make connections with the main shaft at the 575-foot level of the Temiskaming mine the drills cut a large vein, which recent developments improve to be one of the best on the property. The vein was located only ten feet from the shaft, and from all appearances is an entirely new ore body unless it has maulted from the of ohe upper levels. It shows a width of from one foot to two and a half feet, and in places carries exceptionally high-grade ore. However, it is very patchy, and in places will run as high as 5,000 ounces to the ton, while in other places it will be much lower. As only 15 feet of drifting has been accomplished on the vein it is hard to estimate just what possibilities the vein offers, but should a persistent ore shoot be encountered it will be one of the largest producers on the property.

With the addition of ten more stamps about a month ago, the concentrator is now treating between 125 and 130 tons of ore daily. This, with high-grade being bagged underground, brings the Temiskaming shipments well up to two and three cars of high-grade a month. Fifteen large drills are working underground, while there is a force of 175 to 200 men on the payroll.

Cobalt, Sept. 6.—More bullion left the camp yesterday afternoon, this time the O'Brien and Drummond being the shipper. The O'Brien sent out 18 bars of the refined silver, containing 16,553 ounces, and valued at $8,773, to Mocatta & Goldsmid, London, England. The Drummond shipment consisted of two bars sent out by Campbell & Deyell's sampling works. It was consigned across the water and leaves with the O'Brien consignment on the Empress of Britain on the 8th. The two

bars were worth $681 and contained 1,288 ounces of silver. To-day a one-bar consignment from Campbell & Deyell sent out for the Wettlaufer mine of South Lorrain, goes to Bridgeport, Conn.

Porcupine, Sept. 5.—The Messrs. Drummond, of Montreal, who recently acquired control of the Jupiter property, have been in the camp inspecting the property, and have placed an order for a compressor. Two shafts on the Jupiter are down 100 feet, and cross-cutting for the veins has begun. At the 50-foot level considerable development has been done, with satisfactory results.

Porcupine, Sept. 5.—The directors of Crown Charter Mining Company have decided to go ahead with active development work on Davidson claim. They recently acquired this property, and, under advice of Engineer Lamb, they determined to push development work.

BRITISH COLUMBIA.

Ymir, B.C.—The operators of the Sterling mine have just encountered over four feet of high grade ore, showing some galena, having got in under the rich showing exposed on the surface. The vein on the Jennie Bell has been found in place and rich ore encountered, containing some galeua. A recent assay gave $119.50 over all, $57 of which was in gold.

Joe. Kileen, J. B. Bremuer and wife have kept the development work going along ever since the rich discovery was made and they say that ore will be sent down Wild Horse Creek as soon as the winter sets in from the Jennie Bell.

A. E. Rand, C. W. Riley, E. Nelson Fell, M.E., and other mining men of note paid the Dundee mine a visit of inspection last week and expressed themselves as well pleased.

The formations of this camp are attracting the attention of mining men and all agree that it is only a matter of time before the locality will be dotted with producing mines.

Nelson, Sept. 4.—At midnight Saturday night the huge plant of the Hill Mines Smelter, covering thirteen acres of ground, worth $750,000, and one of the largest plants of its kind in Canada, was a mass of blazing, crackling ruins. Nothing is saved except the seven miles of rail running from the smelter to the Silver King mine on Lode Mountain, the tall, blackened chimneys, and one storey buildings used as an office. Everything else, the huge smelters, the tramway terminal and dump, the assay office, the bridge house and numerous smaller buildings, are a tangle of blacking timber and twisted iron.

The disaster is the work of an incendiary, who for the past two weeks has started a dozen fires, three of which have entailedd enormous loss. On Friday night Nelson Brewery was burned to the ground with a loss of $50,000.

At noon a watchman discovered a fire in the smelter, which he thoroughly quenched, and had arranged for extra guards. At nine o'clock, just after he had hade his rounds of the buildings, fire broke out, and within a few minutes the plant was a blazing furnace, by midnight the entire plant was practically consumed. Nothing could be doue to save the building.

From the assay office a few valuable chemicals were saved. The furniture in the buildings used as residences and stored in other buildings, was carried out by hundreds of willing hands, and saved. All else weut up in smoke.

The Hill Mines Smelter was formerly used to treat the ores of the Silver King and other famous properties on Lake Mountain, Morning Mountain, and adjacent territory, and employed hundreds of men. It had been operated for the past five years, but a Vancouver syndicate, promoted by R. S. Lunnof, Vancouver, has lately effected a consolidation of the Lake Mountain properties, acquiring the mines and smelter. The last payment on the properties was made only last week. The smelter was insured for $50,000. There is no clue to the incendiary.

Vancouver.—The Granville Mining Company, capitalized at $8,000,000, is a new merger of Klondike properties just organized by A. N. C. Treadgold. Mr. Treadgold has just spent six months in London and New York in connection with the flotation of the big enterprise of which he is head. He says all the capital required for placing it on a sound basis is secured. The holdings have been transferred to the new corporation, which will operate on a large scale as soon as the equipment of dredges and hydraulic plants can be got on the ground and long ditches built. Included in the power plant on the north fork of the Klondike River, supplying electric power to operate dredges and plants on various creeks, also the large area of claims owned by the Domiuion Mining Company, Limited, and the Treadgold holdings of placer claims on Dominion, Quartz, Flat, Hunker, and Sulphur Creeks, whence millions of dollars worth of placer gold were extracted in the early days. The claims of the Klondike Mining Company, known as the Boyle concession and embracing over ten miles of the richest dredging ground, may be included in the big merger. The total area transferred to the new company will approximate several hundred square miles. Both dredging and hydraulicking methods will be employed. Mr. Treadgold has sailed for Skagway, accompanied by H. Orr-Ewing, a London capitalist, who was associated with him in the ownership of the original Treadgold concession.

YUKON.

Dawson City.—Mining activity is general in the districts tributary to Dawson, and favourable reports are being returned from all bona fide operators. This is the substance of a lengthy report just received at the offices of the White Pass & Yukon route from their accredited agents in the north. It is rumoured in mining circles, the report states, that the properties at present controlled by the Treadgold interests are to be acquired for a wealthy South Africau mining company. This report can uot be confirmed at this time, but material is on the ground for the coustruction of an electric power liue to the properties from the Granville Power Company plant, and plans are under way for the renewal of mining activity in that district.

The Granville Power Company has material at haud for the installation of a second unit of power, a work that will be completed at once. The company is at present supplying power to the Canadian-Klondike Mining Company, which is operating two dredges successfully.

The Yukon Gold Company is operating a full complement of dredges and hydraulic plants and making regular shipments of bullion. The management has 150 men at work constructing the two steel dredges shipped this year, that, when completed, will be installed, one on Bonanza Creek, and the other on Eldorado. This company is making a very interesting experiment with coal as a substitute for wood fuel for the thawing of the earth covering the ore bodies.

The wood supply is becoming scarcer each year, aud as they use nearly 15,000 cords of wood annually, they plan to resort to coal in future, as they can obtain a good quality in the district and find it much more easy to handle than wood.

A stampede was made recently to the lang aloug Britannia Creek, on the maiu Yukon River, a few miles from Coffee Creek. More or less actual work has beeu done and the verdict is that claims in that district will pay, not heavily, but better than a wage proposition for commou hand mining. It is stated that with machinery or a dredging outfit the return would be large. Another stampede was made a short time ago to Mc-

Millan River, a tributary of the Pelly, but the ore is low grade, and will hardly pay the expense of working.

Nanson Creek district sends in good reports, although a small paying proposition. This district is near Carmacks, and one or two concerns with machinery are doing well.

In the Forty-mile district the Milvain people are operating two dredges very successfully. The Consolidated Gold Dredge Company has one dredge on Forty-mile River that sank this spring. The company is having some difficulty in raising , but expect to do some work befcre the season closes.

The Northern Light, Power and Coal Company has clos its plant at Coal Creek and reduced the working force fr 150 to 10 or 15 miners. They are getting out some coal t is being towed to Dawson by their steamer Lightning, a disposed of in that city at their local electric lighting pla and to such other companies as they have contracted to supp

COMPANY NOTES

WETTLAUFER DIVIDEND.

At a meeting of the Wettlaufer Lorrain Silver Mines, Ltd., the regular dividend of 2½ per cent., with 2½ per cent. extra was declared payable October 20, to stockholders of record October 10.

Several important pieces of development and construction work were decided on at the meeting. Among these were the sinking of the main shaft to the sixth level and the drifting on that level for the purpose of exploring the ore bodies in depth; the erection of a picking and jigging plant for the plant for the purpose of sorting the ore and treating the low grade material; and the construction of a house and suitable quarters for the manager.

NIPISSING BULLION.

Nipissing made another shipment of bullion last week to New York, consisting of 47 bars, containing 50,462 ounces of silver. The shipment was valued at $26,366.

LA ROSE PRODUCTION.

The following table shows the operations of the La Rose Company by months since January 1st last:

	Production, ounces.	Gross value.	Operating profit.
January	318,187	$166,468	$118,497
February	307,661	158,135	108,891
March	.....	.....	98,873
April	289,895	155,548	101,325
May	314,543	167,195	103,745
June	310,524	162,816	104,683
July	.....	172,881	105,121

MILLERETTE SHIPMENT.

An ore shipment aggregating 41,600 pounds was sent out by the Millerette mine at Gowganda last week. The consignm was shipped via Latchford and the T. & N. O.

T. & H. B. DIVIDEND.

The Temiskaming and Hudson Bay Company has just clared one of its customary dividends of 300 per cent., p able August 31. This is the fourth of the kind this year, a the third in three months. The dividend makes the 32nd t the company has declared since its inception, and means total of 18,400 per cent., or a total of $1,428,024.

Shareholders have received d$184 a share in dividends to da

BIG PRODUCERS OF COPPER.

For years the Calumet & Hecla was the premier cop mine of the world, both from the viewpoint of production a dividends, but having reached the limit in point of producti other mines have, within the past few years, surpassed it both production and dividend rate, leaving the Calumet Hecla in fourth instead of first place. The Utah Copper Co pany, which was an undeveloped prospect six years ago, day leads the world's copper mines in amount of divide paid. The record of the five leading producers follows:

Company.	Production. 1910	Divide Paid, 19
Phelps-Dodge & Co.	116,688,000	$4,500,0
Utah Copper Co.	84,502,475	4,619,0
Amalgamated	233,808,546	3,065,7
Nevada Con.	62,772,342	2,988,9
Calumet & Hecla	71,509,261	2,800,0

The production of the Phelps-Dodge Company comes fr three mines, at Bisbee and Morenci, Arizona, and Nacoza Mexico, while the production of Amalgamated comes from dozen different properties on Butte Hill.

STATISTICS AND RETURNS

COBALT ORE SHIPMENTS.

Following are the shipments from the Cobalt camp for the week ending Sept. 1, and those from Jan. 1 to date:

	Sept. 1. Ore in lbs.	Since Jan. 1. Ore in lbs.
Badger	.....	55,200
Bailey	.....	40,000
Barber	.....	6,000

LAKE IRON ORE SHIPMENTS.

Following are the iron ore shipments from upper lake ports as reported from month to month, with revised totals of the season movement, together with the all-rail movement by years, this not being compiled monthly, the grand totals of movement out of the region and the lake movement to September 1st. Based on the average of shipments during the preceding four years, the shipments through August indicate a total movement this season, by lake and all rail, of about 33,000,000 gross tons.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining ineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show s of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a rough knowledge of Mining Law, should be very careful with whom they place their business.

DEPARTMENT OF MINES. GEOLOGICAL SURVEY.

PUBLICATIONS

The Geological Survey has published maps and reports dealing wi a large part of Canada, with many local areas and special subje s.

A catalogue of publications will be sent free to any applicant. A single copy of a map or report that is specially desired wil e sent to a Canadian applicant free of cost and to others at a nominal price. The applicant should state definitely the precise area on- cerning which information is desired, and it is often of assistance in filling an order for a map or report if he states the use for wh it is required.

Most of the older reports are out of print, but they may usually be found in public libraries, libraries of the Canadian Mi g Institute, etc.

REPORTS RECENTLY ISSUED:

CANADA

1085. Descriptive Sketch of the Geology and Economic Minerals of Canada. Accompanied by a geological and mineral map Canada, by G. A. Young and R. W. Brock.
1170. Summary Report of the Geological Survey for 1910.

NEW BRUNSWICK and NOVA SCOTIA

1113. Memoir No. 16. The Clay and Shale Deposits of Nova Scotia and portions of New Brunswick, by H. Ries aud J. Keele

1149. Map 21A. Saanich sheet, Vancouver Island, B.C., topographical. Scale 1 mile to 1 inch.
1164. Map 28 A, Sketch map of Portland Canal Mining District.

YUKON and NORTH WEST TERRITORIES

1089. Map 9A. Explored Routes on Parts of the Albany, Severn and Winisk Rivers. Scale 8 miles to 1 inch.

NOTE.—Maps published within the last two years may be had, printed on linen for field use. A charge of cents is made for maps on linen.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and econom geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature r ported upon. Letters and samples that are of a Departmental nature, addressed to the Director may be mailed O.H.M.S. free of postag

Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.

BRITISH COLUMBIA

The Mineral Province of Western Canada

Has produced Minerals valued as follows: Placer Gold, $71,213,103; Lode Gold, $60,811,067; Silver, $31,095,602; Lead, $24,645,605; Copper, $60,743,405; Other Metals (Iron, Zinc, etc.), $1,083,172; Coal and Coke, $114,012,596: Building Stone, Brick, etc., $10,593,100; making its Mineral Production at the end of 1910 show an

Aggregate Value of $374,197,650.

In 1910 the quantity of Ore mined was 2,216,428 tons, and of coal 3,139,235 long tons. The value of Minerals produced that year was: Placer Gold, $540,000; Lode Gold, $5,533,386; Silver, $1,245,016; Lead, $1,386,350; Copper, $4,871,512; Coal and Coke, $11,108,335; Other Minerals, $1,692,473, making the

Total Value for 1910, $26,377,066.

Lode mining has only been in progress for about eighteen years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those in any other Province in the Dominion, or any Colony in the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with mining Reports and Maps, may be obtained gratis by addressing

When answering Advertisements please mention THE CANADIAN MINING JOURNAL

Province of Quebec

Department of Colonization, Mines, and Fisheries.

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, Etc.

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

MINERS' CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10.00 and it is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $10 an acre for SUPERIOR METALS when more than 20 miles distant from a railway and $20 an acre when less than 20 miles.

For INFERIOR METALS the prices are $2.00 and $4.00 an acre respectively.

The attention of prospectors is specially called to the territory in the North-Western part of the province of Quebec, north of the height of land, where important mineralized belts are known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, MONTREAL, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The Bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

THE HONORABLE THE MINISTER OF COLONIZATION, MINES, AND FISHERIES, QUEBEC

Province of Nova Scotia

Leases for Mines of Gold, Silver, Coal, Iron, Copper, Lead, Tin

AND

PRECIOUS STONES

Titles given Direct from the Crown, Royalties, and Rentals Moderate

Copies of the Mining Law and any information can be had on application to

The Hon. Christopher Chisholm

Commissioner Public Works and Mines, - - HALIFAX, NOVA SCOTIA

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

WANTED

AGENCY FOR ORES AND MINERALS.

An Ore Merchant who has connections with all the blast-furnaces and electro-metallurgical firms of France desires to communicate directly with firms who produce or sell:—

Chrome Ore; India, Brazil, or Caucasus Manganese Ores; Graphite; Tungsten Ores; Molybdenite Antimony Ores; Iron Ores; and Asbestos.

It is desired to purchase Ores outright, or to take over Sales.

AGENCY FOR FRANCE:—

Address—Mr. Ch. CHAUTEN,
123 Rue Lamark, PARIS.

The Best New Books for Mining Engineers

Just Issued

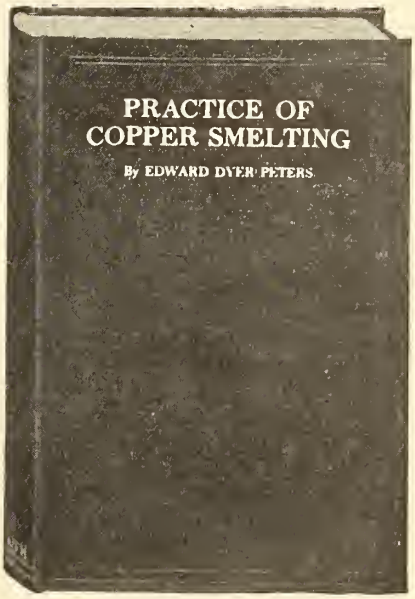
Practice of Copper Smelting

By EDWARD DYER PETERS,
Professor of Metallurgy, Harvard University.

693 pages, 6x9, illustrated $5.00 (21s.) net, postpaid.

This new work is devoted to the modern, actual methods of Copper Smelting with just enough of the principles to give a clear picture of the reasons for each stage of the operation.

It is the fruit of the author's wide experience and extensive research coupled with the information offered by the principal American Smelting Companies.



Dr. Peter's book presents many important matters which cannot be found elsewhere. It tells of the use of Oil as fuel in reverberatory smelting; pulverized coal in reverberatories; modern converter practice with actual results and costs; the basic lined converter with plans; "Fines"; "Slags"; etc.

It is a companion volume to "Principles of Copper Smelting"

Principles of Copper Smelting

612 pages, 6x9, $5.00 (21s.) net, postpaid.

Modern Copper Smelting

600 pages, 6x9, $5.00 (21s.) net, postpaid.

Mining Books

Underground Surveying

Corrected Edition.
By LOYAL W. TRUMBULL, E.M.
150 pages, 6x9, illustrated, $3.00 (12s. 6d.) net, postpaid.

Compressed Air

By ELMO G. HARRIS, C.E.
Professor of Civil Engineering, University of Missouri School of Mines.
136 pages, 6x9, illustrated, $1.50 (6s. 6d.) net, postpaid.

Timbering and Mining

By W. H. STORMS.
200 pages, 6x9, illustrated, $2.00 (8s. 6d.) net, postpaid.

Principles of Mining

By H. C. HOOVER.
300 pages, 6x9, illustrated, $2.50 (10s. 6d.) net, postpaid.

The Cost of Mining

By JAMES RALPH FINLAY.
415 pages, 6x9, illustrated, $5.00 (21s.) net, postpaid.

Tables for The Determination of Minerals

Rock Drills

Design, Construction, Use
By EUSTACE M. WESTON
367 pages, 6x9, illustrations, $4.00 (17s.) net, postpaid.

Describes the leading modern makes of English, Australian and American drills. It assists in choosing machines most suited to particular needs, and using them with the greatest efficiency.

Practical Shaft Sinking

By FRANCIS DONALDSON, M E.
143 pages, 6x9, illustrated, $2.00 (8s. 6d.) net, postpaid.

The author presents an immense amount of good material in a small space. It is a *timely* volume for mining engineers.

Principles of Metallurgy

By CHARLES H. FULTON,
President and Professor of Metallurgy, South Dakota School of Mines.
536 pages, 6x9, illustrated, $5.00 (21s.) net, postpaid.

The standard work on this subject. The treatment of the subject is modern. The author presents new ideas, and the style is clear and terse.

Books on Metallurgy

Clennell's Cyanide Handbook

By J. E. CLENNELL.
526 pages, 6x9, illustrated, $5.00 (21s.) net, postpaid.

Ore Dressing

By ROBERT H. RICHARDS,
Professor of Mining and Metallurgy, Massachusetts Institute of Technology.
Four volumes, 2,000 pages, 6x9, illustrated, per set, $20.00 (£4 4s.) per volume, $5.00 (21s.) net, postpaid.

Elementary Crystallography

By W. S. BAYLEY, PH.D.,
Associate Professor of Mineralogy and Economic Geology, University of Illinois.
236 pages, 6x9, 300 illustrations, $2.00 (8s. 6d.) net, postpaid.

Metallurgy of Lead

and the Desilverization of Base Bullion
By H. O. HOFMAN.
600 pages, 6x9, illustrated, $6.00 (25s.) net, postpaid.

Metallurgical Calculations

By JOS. W. RICHARDS.
Three volumes, each volume over 200 pages, 6x9, $2.00 (8s. 6d.) net, postpaid per volume.

ANNOUNCEMENT

THE CANADIAN MINING JOURNAL'S

PORCUPINE SERIES

VOLUME I.

A SERIES OF UNIQUE ILLUSTRATED ARTICLES.

Accompanied by a Complete Geological Map and Claim Maps of the Various Townships

The Publishers of *The Canadian Mining Journal*, in view of the fact that the demand for back numbers containing articles on Porcupine cannot be met, are bringing out a book embodying descriptive, geological, and general data relating to Porcupine. The latest available township maps and a large Geological Map will be included. The object of the publishers is to present in compact form a book that will guide the investor, the engineer, and the general reader.

The book will be on sale within a few days.

The price is $2.00 per volume. For orders of more than ten volumes a reduction of ten per cent will be made. The edition is limited.

Canadian Mining Journal, 17-23 Manning Arcade Annex, Toronto

AIR COMPRESSORS FOR EVERY SERVICE

Made by the LAIDLAW-DUNN-GORDON CO., Cincinnati.

MINING & SCIENTIFIC PRESS

Controlled by T. A. Rickard — **Established 1860** — **H. Foster Bain, Editor** — **Published weekly** — **Thomas T. Read, Associate Editor**

In every issue valuable articles are published on mining, metallurgy, and geology, the latest news from special correspondents at the principal mining centers, letters giving the ideas and experience of successful men, and other items of useful knowledge.

THE MINING MAGAZINE

Established September, 1909

T. A. RICKARD, Editor — **Published monthly at London, England**

A monthly magazine is the natural corollary of a technical weekly. It permits of more deliberate and more extended notice of matters concerning which the news element is less important.

The Mining Magazine includes a review of the world's progress in mining, metallurgy, and economic geology, written by men who have personal knowledge of the regions and conditions discussed.

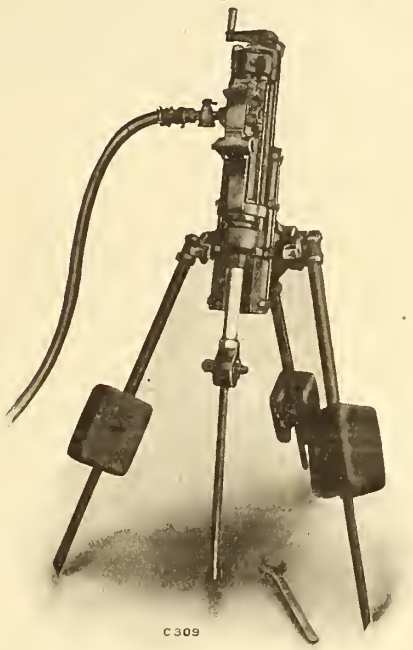
"RAND SLUGGER"

ROCK DRILLS



The Rand Slugger Drill is a successful combination of the positiveness of the rocker thrown valve and the sensitive, economical and quick action of the independent air thrown spool type.

In the "Slugger" design the main valve is thrown by compressed air controlled by a small vertical auxiliary valve, actuated by the rocker which in turn is operated by the piston. This device gives a light quick valve motion in which the positive operation of the rocker thrown valve is combined with the advantages of the air thrown spool type.

The "Slugger" strikes a powerful uncushioned blow with lightning like rapidity and although it has only been on the market a comparatively short time, has found great favour among the admirers of the air thrown spool valve.

The substitution of steel parts for those of cast and maleable iron in the construction of this drill means reduced maintenance costs and sustained high efficiency.

The great variety of special materials obtainable and our facilities for special treatment of materials make possible the construction of a highly superior machine which will stand up to continuous rough usage and hard service without rapid deterioration. This design is a thorough exemplification of such construction.

Amatite ROOFING

FOR MINE BUILDINGS

AMATITE is exactly suited to mining buildings because:

1—It can be laid by unskilled labor.

2—It has a real mineral surface *which requires no painting.*

3—Its cost is lower than that of other ready roofings of less weight.

4—It comes in rolls ready to be unrolled on the roof and nailed down.

5—The necessary nails and cement are supplied free, packed handily in the centre of each roll.

The mineral surface of Amatite is somewhat of a novelty: and the fact that it obviates the old painting nuisance, is giving to this roofing the leadership of the ready roofing industry.

The surface consists of mineral particles embedded under great pressure into a tough plastic matrix of pitch.

A sample of Amatite will be sent free on request.

Four Good Reasons

WHY A WATEROUS PUMP WILL MAKE GOOD AT MINE WORK:

1.—**It is simple in construction.** It is built of few parts, there are no valves to get out of order, no restricted water passages to clog up; there is not a complicated piece in its whole make up.

2.—**It is built strongly throughout.** Wherever wear is likely to occur the casting is re-inforced and strengthened to resist it. The materials used are selected, and the careful way parts are put together prevents wear and consequent slackness.

3.—**It is easy to operate.** It can be left in care of an unskilled laborer without danger. All that is necessary is to start it and shut it off when the whistle blows. Overhauling and cleaning are made simple by the split-base and split packing gland—special features of this pump.

4.—**It is compact and comparatively light.** It can be quickly and easily moved from place to place and will work well in almost any position.

In sizes up to 14 inch discharge opening. Write for Catalogue No. 200.

Why the C.P.R. North Toronto Route to Ottawa and Montreal is the Logical One

The train leaves as follows:

Leave North Parkdale - - -	9.15 p.m.	Leave West Toronto - - - -	9.30 p.m.
Arrive North Toronto - - -	9.40 p.m.	Leave North Toronto - - -	10.00 p.m.
Arrive Ottawa, 6.50 a.m.		Arrive Montreal, 7.00 a.m.	
Daily.		Double Electric Berth Lights.	

¶ The residents of Toronto are adjacent to either North Parkdale, West Toronto or North Toronto stations, same being easily accessible and close to residential districts.

¶ The North Toronto route is over an hour faster and overcomes a long hill climb for the train out of Toronto obviating any inconvenience and ensuring early arrival at Montreal and Ottawa.

¶ The roadbed has been improved till it is unexcelled in Canada. Practically half the line is double tracked.

¶ The equipment is "Canadian Pacific Standard," a synonym for the "best" and attentive porters, ensure efficient service.

THE ELECTION.

We are not a nation of prophets. The overwhelming events of September 21st were unexpected by the shrewdest political diagnosticians. Never has a Canadian government been so finally defeated on an issue of grave national importance Never has the nation spoken with so little regard for political colour. Although, as is usual under our system of party government, the Conservative party reaps the glory and benefits of the election results, a deeper significance than party victory underlies the occasion.

Canada has definitely refused to endorse the reciprocity pact. This is not a hostile demonstration against the United States. It is, on the other hand, a dramatic declaration of Canada's desire and intention not to imperil her place in the British Empire. That the acceptance of the Taft-Fielding pact would have weakened the Imperial connection is not for us to say. We may safely leave that question to political journals. But it is certain that the majority of Canadians did think so on September 21st.

Personal sympathy with Sir Wilfrid Laurier, at once the most picturesque and the most magnetic figure in Canadian public life, will be felt and expressed throughout the length and breadth of the land. Of him any nation might well be proud.

Sympathy, also, will be felt for such of his former ministers as have done their duty honourably, a list that is not as inclusive as it might be.

Upon Mr. Borden, as Premier, and upon the cabinet that he will select, lies a profound obligation. Canada has emerged definitely and cleanly into self-respecting nationhood. Solidarity has been attained. It is known, now, that the interests of the nation must rule supreme. How to give those interests definition, how best to forward them, how to preserve harmony between conflicting commercial elements — these are the problems.

As Canadians we cannot but follow the whole trend of Canada's growth. As mining men we are particularly concerned with the new Government's policy in regard to the mining industry.

The first and, in itself, the one step that will determine the success or failure of the Government's mining policy will be the selection of a competent, enlightened, and vigorous Minister of Mines. Naturally this must be a totally independent cabinet position, and the jurisdiction of the Minister must be complete. It must include the function now anomolously assigned to the Department of the Interior, namely the administration of mining lands in Alberta, Saskatchewan, and Yukon Territory.

Any Minister selected will prove an encumbrance unless he surrounds himself with experienced advisers and keeps constantly in touch with the industry. Therefore it is imperatively necessary that the Minister, unless he is to be a figurehead, be forearmed with a knowledge of what mining means to Canada. In other words, he must have had occasion to study conditions at first hand.

We seize this opportunity of pronouncing our views because experience has convinced us that, of all our industries, that of mining is most in need of careful attention from Ottawa. This assertion needs no laboured proof.

* * * *

Before our new Premier and his Minister of Mines lies a supreme opportunity. Canada can easily improve her position in the mining world. But much will depend upon Ottawa. The revision and codification of our mining laws, a measure already begun, must be completed at an early date. The questions of handling explosives, of rescue work in coal mines, and similar problems can best be met by the Federal Mines Branch. Provincial Departments will follow the lead set by Ottawa.

There is no doubt that the erection of a vigorous Department of Mines at Ottawa, under a competent Minister, will mark the inception of a remarkable development in Canadian mining. We cannot too strongly urge upon the new Government its duty in this respect.

THE ECONOMICS OF TUBE-MILLING.

A remarkably exhaustive thesis, the work of Mr. H. Standish Ball, M.Sc., has just been published in the Bulletin of the Institution of Mining and Metallurgy, of which body Mr. Ball is a student-member. Mr. Ball undertook the work in order to acquire his M.S.C. degree at McGill University, and also to do his duty as the recipient of the Research Scholarship awarded by the Transvaal Chamber of Mines in the year 1909.

Working under the general direction of Dr. J. Bonsall Porter, Mr. Ball made an analysis of the conditions that determine the efficiency of tube-milling. Sketching first the growth of tube-milling practice, he touches upon the factors controlling efficient work, outlines the tests proposed and the tests actually carried out, the general theories of rock crushing, describes the equipment used, and then proceedsd to give a detailed account of each experiment.

The rock used was a hard, compact, nepheline syenite. The tests were divided into four series, in the first of which the feed was varied, the moisture, pebble load, and revolutions per minute remaining constant. In the second series, the moisture was varied; in the third, the pebble load; and in the fourth, the speed.

The preparation of the rock proved to be an unexpectedly arduous task. After reduction to -¼ in. through a "Comet" crusher, 14 tons had to be crushed in a 5-stamp battery through a screen of 18 holes to the linear inch, and de-slimed in a classifier. The sands were then dried, weighed, and stored.

The mill used was formerly an old chlorination barrel, the outside dimensions of which were: length 4 ft. 8in.; diameter, 3 ft. 5 in. The inside dimensions were: length, 3 ft. 6 in.; diameter, 2 ft. 10 in. The true shell was built of ⅜-in. steel, bolted to cast iron end pieces, 2 inches thick, which were stiffened by six 2-inch ribs. The lining consisted of 8-inch by 4-inch by 2½-inch Silex bricks, set in patent cement. An iron screen, with ¾-inch holes, was fixed at the discharge end. 18-mesh sand was delivered by means of a pipe from a bucket elevator to the cone, the size of the discharge orifice being regulated by means of carefully calibrated caps with different sized apertures.

The barrel was driven by a chain and sprocket gearing, and revolved on hollow trunnions. The stamp battery consisted of five 600-lb. stamps, the total crushing capacity being 800 lbs. per hour.

The amounts of rock used in each test ranged from 800 lbs. to 2,000 lbs. After careful screening of the sand through ⅛-inch screen, the water was measured and the flow adjusted. The time consumed by each test varied from 45 minutes to one hour. Thorough screen analyses checked every trial.

It is impracticable here to follow the elaborate tests conducted by Mr. Ball. It must suffice to note some of his conclusions. From figures adduced throughout the experiments, it is indicated, provided there be a fair basis of comparison between the large mills in use in South Africa and small mill used by Mr. Ball, that the present general tendency is to overfeed. That is, the "critical feed," is exceeded, power is wasted, and the results obtained are not commensurate with the material and power used.

As regards moisture, the fact is demonstrated that 37.7 per cent. is much more advantageous than any other proportion. This corresponds more or less closely, with the conclusions of other investigators.

The pebble load tests tended to show that the highest efficiency is reached when that load has a volume of 7/16 the volume of the mill.

The conclusion that a peripheral speed of 333 feet per minute, or 37 revolutions per minute, is most efficient is in close accord with results obtained by Richards and others.

Mr. Ball's paper is an excellent student production. It exhibits evidence of care, thoughtfulness, and ability. It is open to certain criticisms, as, for instance the fact that several of the curves, notably those displaying "moisture efficiency" and "moisture power," are based upon quite insufficient data. Generally this applies to the whole paper. There is no adequa

ason adduced for instituting close comparisons beveen the improvised tube mill and the large mills iat are used in actual practice. Hence there are ips in Mr. Ball's demonstration.

Yet the paper is most creditable as the effort of a udent working under all the disadvantages of the sual laboratory equipment.

COMPANY PROMOTION.

As chairman of the Western Branch of the Canadian lining Institute, Mr. Robert Hedley delivered a noteorthy address at the last gathering at New Denver, locan Lake, B.C. The leading topic touched on by Ir. Hedley was the subject of company promotion for ining enterprises.

The substance of Mr. Hedley's speech was to the effect that discreditable mining enterprises can be nipped in the bud if proper precautions be taken. In the rst place, there must be reasonable grounds for beeving that ore exists in commercial quantities in any iven prospect. This is one of the considerations glossd over by the promoter and rarely investigated by the asual investor. Secondly, the proposed distribution f capital contributes to kill whatever chance of sucess there may be. Thirdly, competent management an never be expected in connection with unsound floations. Fourthly, even if the physical aspects of the roposition be favourable, disproportionately small ums are provided for working capital, and the market for shares is overwhelmed with promotion scrip efore that working capital can be raised.

To meet these conditions, Mr. Hedley proposed that t be made a misdemeanour to "promote a company to 'operate a mine that has little, if any, reason to hope 'for commercial ore; so to distribute the capitalization 'that the treasury is inadequately supplied; to place 'the management in grossly incompetent hands; to 'sell promoters' shares before the property has been 'developed beyond the prospect stage.''

Mr. Hedley, of course, merely reiterated the opinons of all respectable mining men. His suggestions iave been made and discussed many a time and oft. All of them deserve close attention.

Taking these suggestions in order, it may be pointed ut that there is so much room for difference of expert pinion as to the merits of a prospect that the first suggested misdemeanour hardly comes within the scope of legislation. All that is really necessary is that the opinion of a competent and disinterested mining engineer be obtained. On the other hand, the matters of organization and distribution of capital shares are readily controllable. This is immediately the duty of each Provincial Government. As to the character of the management, the only way in which efficiency can be guaranteed is by securing legislation that precludes the incompetent man from mine management.

British Columbia laws already guard against the unqualified assayer, and require strict certification of coal mine managers. Why this measure cannot be enlarged so as to embrace the management of metalliferous mines, we cannot see.

We are in hearty accord with the opinion that it should be made a misdemeanour to place promoters' shares upon the market before a mine has been developed. But this restriction will require official definition in each instance. If a time limit be set, evasion of the law will be easy; but the public will have been given a chance of finding out what it is buying. If official sanction be made a condition, abuses will almost certainly be created.

The time limit, one year possibly, appeals to us as the most rational provision. The other essential is the establishment of a constant relation between promotion stock and treasury stock.

Canada's credit in the eyes of the world rests to a larger extent than ever before upon mining flotations. It is high time to do a little housecleaning.

JUSTICE.

On Monday, September 25th, a "high-grader" named Mountell, who had been found with about 150 pounds of silver in his possession, and who was alleged to have operated as a "fence" in the Cobalt region, was tried before Judge Winchester in the Court of Criminal Sessions, Toronto.

No evidence was heard, or, at best, only a tithe of the evidence was taken. The man was allowed to escape with a fine of $200.

It is unimaginable that Judge Winchester did not know that under Section 224 of the Criminal Code it is made a criminal offence for a person who is not the owner of a mine, or the authorized agent of an owner, to buy or sell silver or silver ore. We have reason to believe that the evidence against Mountell was unusually complete. In any event a fine has nothing to do with the case. The accused should have been acquitted or condemned according to law and not according to Judge Winchester's vagaries. Such conduct on the part of our judiciary is both mischievous and pitiful.

EDITORIAL NOTES.

The fourteenth annual session of the American Mining Congress has been postponed from September 26th to 29th, until October 24th, 25th, 26th, 27th, and 28th. The reason of the postponement was the fact that President Taft could not attend on the former dates.

From our British Columbian correspondent's note it will be seen that, as at July 1st of this current calendar year, there was due on lead bounty the sum of $832,979.68. The total appropriation made by the Dominion Government was $2,500,000. The total amount paid before that date was $1,617,020.32. Of this, the sum spent up to June 30th, of this year, is $49,713.32.

Upon Mr. J. M. Clark, K.C., who has been large instrumental in the recent codification of the mini laws of the Dominion, has been conferred the hono of election to the Honorary Council of the North B tish Academy. The Academy is a notable scienti society amongst whose officers are such persons the Right Hon. Viscount Milner, Field Marshall Ea Roberts, and the Right Hon. A. J. Balfour.

CORRESPONDENCE

COMPULSORY CERTIFICATES FOR MINE MANAGERS.

Editor Canadian Mining Journal:—

Sir,—What has played a prominent part in hampering the progress of the mining industry is the fact that the management of a large proportion of the mines has been left in the hands of men who are incompetent to fill such responsible positions. By paying a visit to some of the mining districts and observing the methods employed in carrying on operations it is possible to see where instances of incapable management have been the cause of squandering thousands of dollars. This fact alone demonstrates the need of establishing a strict standard of efficieney for the mine manager.

In order to establish a higher standard for men engaged in this branch of the profession, the urgent necessity for legislation compelling an examination in certain mining essentials is obvious. The passing of an Act of Parliament to this general effect would not only protect the industry but would raise the standard of competent mine managers to a higher plane. Certain reservations could be made in favour of men who have had years of practical experience in underground work. In some cases sueh men are of equal value to the industry as their technically trained brothers, particularly where mining properties are free from complexity of geological structure and chemical combination. It would be a hardship to the man who has graduated through the underground workings of a mine to exclude him from a higher position for the sole reason that he has not had the opportunity to secure a scholastic training. Cases of this kind could be taken care of in the arrangement of details. It is a matter of vital importance to the mining industry that practical experienee be not overlooked. Nevertheless the science of mining makes technical training absolutely necessary for the mine manager. A man who has taken a course in a school of mining, added to years of practical experience, is better fitted for the office than a man who has had no technical training.

For many years the mining fields of Canada and the United States have been the hunting ground for the unqualified man. Men of this character apparently overlook the fact that it is a grave misdemeanour to accept a position as mine manager when they are not qualified to fill the offiee—no matter under what conditions the position may have been secured. Positions as mine manager are often obtained through the influence of friends for men who have not the slightest knowledge of even the rudiments of mining, and in many cases the final result has been the closing dov of prospects before they have had an adequate te

Some idea of the clamant need for the certificati of the mine manager may be gathered from the fa that before a man is allowed to take charge of a boil and engine he is compelled to produce a certificat The lives of men are in his hands. None other but thoroughly reliable man is allowed to take charge a hoist, yet the mine manager is the hoist man's s perior offieer. His responsibilities are more divers and he is, to a great extent, responsible for the doin of the hoist man, therefore it is apparent that the should be some law eompelling the man in charge the hoist driver to pass an examination in mining ma ters before he is considered competent to fill such responsible position.

The question of certificating mining managers of sufficient importanee to warrant the co-operatic of the Minister of Mines with the Canadian Mining I stitute in aequiring the desired end.

Yours, etc.,

George R. Rogers,

Toronto, Sept. 21st.

Personal and General

Mr. G. C. Bateman is still in Porcupine.

Mr. J. W. Evans gave another successful demo stration of the Evans-Stansfield furnace at the Scho of Practical Science, Toronto University, on the eve ing of Sept. 21st. His audience was largely made u of members of the American Electrochamical Societ Much interest was roused, and it is probable that fu ther demonstrations will be arranged. Practical pul licity of this kind is highly desirable.

Mr. W. E. Segsworth, mining engineer, Jarvis Buil ing, Toronto, has returned from a lengthy inspectio of mining properties in Eastern Ontario.

Mr. W. A. Parks, associate professor of geolog University of Toronto, returned to Toronto on Se tember 21st, after being absent the whole summer o official business connected with the Federal Min Branch.

Mr. Kirby Thomas, mining engineer, 20 Broad St New York, recently examined several claims in th West Shining Tree region.

Mr. George P. Dempster, Porcupine representativ of J. S. MacArthur & Co., visited Toronto during th middle of September.

Mr. A. A. Hassan, consulting mining engineer, ha established an office in 11 Royal Exchange Buildin

balt, Ont. Mr. Hassan has started afresh the development of the Cobalt Station Grounds mine.

Mr. Thomas Kiddie, of Vancouver, B.C., was in California recently.

Mr. C. F. J. Galloway, B.Se., son of Professor Galway, of Cardiff, Wales, lately visited the Cariboo strict, B.C., to examine mining property.

Mr. Ernest Levy, manager of the mines of the Le Roi No. 2, Ltd., at Rossland, and that of the Van-Roi Mining Co., Ltd., in Four-mile Creek camp, Sloean Lake, has returned to British Columbia after an absence of about three months, which period he spent in England.

Mr. Wm. Fleet Robertson, provincial mineralogist for British Columbia, returned to Victoria on September 3rd from an official visit, extending over nearly two months, to mines in the country around Hazelton, Skeena River, Cassiar district.

Mr. O. E. LeRoy, of the Geological Survey of Canada, has been making Nelson his headquarters this season while supervising the geological and topographical work of several survey parties engaged in Kootenay and Boundary districts of British Columbia. Field work has been completed in Franklin camp, Boundary district, but there is still much to do in East Kootenay.

Mr. A. L. Larson, formerly superintendent of the Le Roi mine, but now of Vancouver, B.C., made an examination of the Sloean Star group of mines and the adjoining claims of the Star Mining and Milling Co., in connection with an amalgamation of interests that has been arranged between the several parties concerned.

Mr. Robert R. Hedley, of Vancouver, B.C., accompanied by Messrs. Hugh F. Marriott, of London, and G. G. S. Lindsey, of Toronto, paid a visit to Sheep Creek camp, in Nelson mining division, after their return south from a visit to the Skeena River country. Messrs. Lindsey and Marriott immediately afterwards left British Columbia for New York, whence Mr. Marriott proceeded to London.

OBITUARIES.

The death occurred at Atlin, B.C., on September 7, of Mr. Th. Obalski, the manager and mining engineer of La Societe Miniere de la Columbie Britannique. Mr. Obalski was about 50 years of age at the time of his death. Heart failure was the immediate cause. Mr. J. Obalski, formerly Superintendent of Mines for the Province of Quebec, and now a member of the mining engineering firm of Obalski and Dulieux, Montreal, is a brother of the deceased.

ORE SHIPMENT SAMPLING IN COBALT.

(Written for the CANADIAN MINING JOURNAL.)

Exactly two years ago there was published in the CANADIAN MINING JOURNAL a description of a custom sampling plant then about to be built in Cobalt. The men behind the enterprise were Messrs. Campbell and Keyell, of Cobalt.

The idea that animated the enterprise was the recognition of the need of some standard system of valuing the ores locally. The discrepancies constantly noticeable between the sampling done by the shippers and that done by the smelters demanded attention. It was

felt that a local sampler was a necessity. The irregular and very variable ores of the camp presented difficulties that could not be met at each mine. Only a large and well-organized public custom sampler could fill the bill. For more than a year the sampler has been in operation. It has supplied a recognized need and has, moreover, created a larger demand for accurate sampling.

The flow-sheet that accompanies this article is practically self-explanatory. The ore is first crushed to pass a one-inch ring. It then is put through a ball mill giving an 8-mesh product. Here the screened metallics go straight to the bullion furnace, the slag being added to the next shipment of ore. A 3-ton feed tank now takes the ore. Through a spiral conveyor it goes to a quartering machine. Each quarter is treated precisely as quarter No. 1, which is reduced three times in 1/20 cuts.

It will be noted that full provision is made for umpire, control, smelter, and original samples. Moisture samples, also, are obtained on the last cut.

The bulk of the ore, that is, nine-tenths of the original, is transmitted to bagging bins and thence to canvas sacks. It is then weighed and put on board the car for shipment to the smelter.

The contrast between the present flow-sheet and that first proposed (see page 581, Oct. 1st, 1909) is marked. At first it was thought necessary to design two sections, one for low grade ore and one for high grade. As it stands at present, the mill is a unit, capable of sampling any class of Cobalt ore. The system of sampling has been modified, and the whole flow-sheet has been adapted to the changing conditions of the camp. Relatively little of low grade ore is now being shippe from Cobalt. More and more is being concentrate Thus scrupulous care is needed in handling satisfa torily the high grade ore sent to the sampler.

Every established mining camp that sends its pr ducts to outside smelters should possess an indepen ent sampler. Both the shipper and the buyer benef thereby.

RESEARCH WORK ON CERTAIN NOVA SCOTIAN GOLD ORES.

By Ora Willis Knight, M.Sc., D.Sc., Bangor, Maine, U.S.*

During the summer of 1910 I spent several weeks studying a number of the anticlinal gold districts of Nova Scotia, and since returning to my laboratory at Bangor, Maine, I have been engaged in a continuous series of investigations, both physical and chemical, of quartz, associated minerals, ores, slates, and quartzites, all of which were personally secured by me in Nova Scotia or in two instances were furnished me through the kindness of Mr. Holman.

This original work has been supplemented by a study of the geological literature of Nova Scotia, including a set of the maps of the various gold districts furnished me through the kindness of Mr. E. R. Faribault, and from a study of these maps alone it is possible to arrive at some very valuable conclusions.

My investigations were conducted on behalf of the Caribou Gold Mines, for which I was retained by Mr. C. Vey Holman, president of the Caribou Gold Mines and state geologist of Maine, and Mr. Holman has generously desired to place such of this privately acquired information as may tend to prove of value in aiding the future mining development of the province, at the disposal of its mining fraternity.

Discovery of Platinum.

Five weeks in all were spent in Nova Scotia, much of this time being passed in the Caribou district, but several other districts on anticlinal folds were studied. The names of these other districts cannot at present be mentioned, although it is permitted me to say that on a mine dumy in one of these districts several small crystals of sperrylite, ($PtAs_2$), a native platinum arsenide, were found by me. Though not actually taken from rock in place, there is every reason to believe that the material on the dump actually represented material from an adjoining vein. The gangue mineral containing the sperrylite was quartz, and the chief associated mineral was arsenopyrite, and a magnesia-bearing dike was in proximity. Laboratory tests were applied to this material after returning to Bangor, and the presence of platinum and arsenic in the crystals verified by positive chemical tests. This appears to be the first recorded discovery of platinum in Nova Scotia, but there is no reason why it should not be found elsewhere in the province associated with metallic sulphides such as covellite, tetrahedrite, bournonite, chalcopyrite, arsenopyrite, or other sulphide ores, or as an irregular dissemination in peridotite, pyroxenite, gabbro, syenite, or various basic eruptives, o in serpentine associated with chromite, the presenc of which latter may be considered quite a promisin indication of platinum. Reference to the discovery o selenium and tellurium in Nova Scotian ores will b found on a subsequent page.

Formation of Gold-bearing Rocks and Veins, and Depo sition of Ore.

A careful consideration of all the data at hand re garding the origin of the Meguma series of gold-bear ing rocks of Nova Scotia, would seem to indicate tha it is of pre-Cambrian origin and quite probably Al gonkian. (Cf. Van Hise and Leith, Pre-Cambrian Geo logy of North America, Bulletin No. 360, U. S. Geol Surv., p. 512). The Meguma series has been divide by Prof. Chapman into a lower or quartzite group, th Goldenville formation, and an upper or slate group the Halifax formation.

It seems very probable that the quartzites (Golden ville formation) were deposited as sediments in shal low water under the influence of strong waves and cur rents acting quite constantly for long periods of time with alternating shorter periods of temporarily deep er waters, and slacker currents. Thus we had de posited coarse sandy material alternating with lesse deposits of very fine clayey sediments. When th metamorphic agencies acted on these later on, thick strata of quartzite with intercalated thin beds o slate were formed.

Following the deposition of these sandy sediments there occurred a very abrupt change in the conditions and there was a long time of existing deep waters very moderate currents, and possibly sedimentary ma terial originating in a more distant land mass was being carried and deposited. This material was de posited as a fine clayey mass quite different in appear ance from the coarser sediments beneath. Later this clay sediment became the Halifax series of slates sharply contrasted in appearance and composition with the Goldenville formation beneath. At far later geologic periods other sediments were formed which we will not consider in this paper.

After deposition of the sediments, a gradual up lifting of them took place. A new land mass was rear ed above the water, and ultimately crumpled into a series of parallel anticlinal folds by a powerful, uni form, long-continued pressure exerted from the south. More or less coincidently heat was developed and hot water, bearing silica in solution, permeated the sands of the Goldenville sediments, and by the deposition o

*Abstract of paper read before the Mining Society of Nova Scotia.

silica as a cementing material the quartzites were formed. The interstratified clay sediments were not so readily permeated by the silicifying solutions, so acted on by heat and pressure chiefly they were changed into slates intercalated in thin beds with the quartzites. Similarly heat and pressure changed the Halifax sedimentaries into slates, placed conformably on the quartzites.

These disturbances and metamorphic agencies were directly caused by the intrusion of the granite magma beneath, and took place at a period generally admitted to be later than Devonian. After intrusion of the granite magma which, it must be remembered, was resting under the great pressure exerted by the Meguma series above, a gradual crystallization took place and the various minerals of the granite separated from the magma, until there was left as a final portion excessive quantities of hot water under great pressure and charged chiefly with silica in solution. Finally great convulsions opened fissures extending towards the surface into which these waters poured, and on their upward way were forced laterally through openings formed by the tearing apart of the various thin slatey strata met on the upward course. Silica was deposited in these openings, both the vertical and the horizontal ones, resulting in the one instance in the formation of the fissure veins of quartz, with direct lateral branches forming the so-called bedded leads. There can be no question that practically all of the bedded veins are of a common origin and source and are direct branches of certain of the more prominent fissures, for they clearly branch from the fissures and neither cut nor are cut by them.

At some subsequent period other fissures were opened, cutting directly through the bedded veins as well as the older fissures, and were filled with solutions bearing silica, gold and other minerals. These later disturbances caused faulting, shearing, and fracturing, and many of the bedded veins and earlier fissures were faulted. It seems very probable that in connection with these later disturbances many of the richer oreshoots were formed. The statement of practical miners has appeared in print and several have told me verbally that in their experience in mining in Nova Scotia, while working in zones of faulting, they have generally found the richest ore under the faults, and that a vein which was rich up to a fault was very often barren when located again above and beyond the fault.

In connection with the anticlines of Nova Scotia we find at several localities that the rocks have been forced up into the form of domes, and in the Caribou district we find existing perhaps the most perfect of these domes. It is evident that some powerful force exerted from below forced the rock formations into the shape which gives them their name, nor is it difficult to fully explain what force formed them. At various localities in granite formations there exist very perfect domes or bosses of granite from which all formerly existing rock which covered them has been eroded. It is also not infrequently the case that granite domes have other rock formations covering their sides more or less completely, and still other domes of which only the very tops have been exposed by erosion of the rock formerly covering them, and so on by an almost complete series of intergradations existing in various parts of the world. It seems very certain that the domes of Nova Scotia, existing on the anticlinal folds, owe their shape to the existence of granite domes beneath which were forced up but never subsequently exposed by erosion.

At various places throughout the Meguma series of Nova Scotia, granite outcrops, having been exposed by erosion, and granite dikes also are not uncommon. It is also very certain that granite exists, at no great depth everywhere beneath the rocks of the Meguma series. While partial erosion has exposed the granite in many places, there seems to be no locality in the province where the slates and quartzites both have been eroded sufficiently to expose the granite on one of the domes.

It is quite generally agreed by the authorities that all gold was primarily of magmatic origin, and it is likewise quite certain that the gold of Nova Scotia originated in the granite magma beneath, and, carried up by ascending waters, was finally deposited in the sedimentary formations above. Even as this paper is being written there has come into my hands an article which records the finding of gold in the granite formations southwest of Halifax about the head of Terence Bay and at Pennant. While particulars of the find are lacking, I am inclined to predict that any payore which has been or may be found in these granite formations will be in quartz veins or quartz segregations derived from the granite magma.

The natural solvents of gold are more numerous than commonly supposed, and the several naturally occurring solvents which have the power of dissolving gold at ordinary temperature and pressure have their solvent power increased proportionately by increased temperature and pressure. If such salts as ferric chloride, ferric sulphate, cupric chloride, cupric sulphate or any of the alkaline sulphides are dissolved in water then the resulting solutions are capable of dissolving gold, especially when heated with gold under pressure. Sodium carbonate solution containing dissolved carbon dioxide, and sodium silicate solution containing sodium sulphide or sulphydrate or other alkaline sulphides also dissolve gold. The presence of any compound capable of liberating oxygen, such, for instance, as manganese dioxide in acid solution, increases the solvent power of certain of the beforementioned solutions for gold, while heat and pressure likewise increase their solvent power.

In the Meguma formations of Nova Scotia we find an abundance of pyrite, pyrrhotite, arsenopyrite and other sulphides which, when bronght in contact with descending waters containing oxygen from the air dissolved therein, become oxidized, and soluble salts are formed capable of dissolving gold. Manganese dioxide is also common in the rocks of the Meguma formation, being more or less generally and finely disseminated, especially in the slates. The sulphur of the metallic sulphides named is first attacked and oxidized, and the finally resulting sulphuric acid attacks the iron, copper and other metallic elements of the sulphides, forming at first, in the case of iron, ferrous sulphate and finally by oxidation ferric sulphate, a gold solvent. The descending waters also contain some sodium chloride which, acted on by the sulphuric acid formed, sets free hydrochloric acid, and in the presence of manganese dioxide, chlorine, a solvent of gold. Ferric chloride is also formed and other solvents of gold as well by the complex series of chemical reactions resulting between the descending waters and the metallic sulphides they encounter.

These surface waters descend through various cracks, seams, joint planes, lateral fissures and through the pores of the rocks, becoming charged with solvents

of gold and other minerals, and becoming heated as well as under pressure with depth. These waters of meteoric origin and bearing "ie" salts in solution are very capable of dissolving gold and do dissolve it when brought in contact with it along their course. Finally at great depths and under great pressure these waters are forced into more or less vertical fissures extending towards the surface, and, charged with various salts dissolved from the rocks through which they have passed, they become ascending waters passing through trunk channels to the surface.

The waters entering the trunk channels at various places contain salts of a more or less diverse nature in solution, the nature of these salts varying with the nature of the local constituents of the rocks through which each set of waters has passed. Waters from the magmatic mass beneath also enter the trunk channels, and these are generally reducing waters, containing "ous" salts in solution and likewise containing agents capable of reducing "ic" salts to "ous" salts. Some branches of the trunk channels pour into them waters charged with alkaline silicates, alkaline sulphides, or alkaline carbonates, while other waters are charged with "ous" or "ie" salts. Under these conditions there would mingle in the trunk channels a series of solutions often of more or less neutralizing power, one to another.

It is a fixed law governing chemical reactions that if two or more solutions bearing different salts in solution are mixed together, and by reaction of these different salts on one another any insoluble compounds can be formed, then such insoluble compounds will be formed. In conformity with this law insoluble compounds are formed and precipitated along the course of the trunk channels. Reduction of both temperature and pressure as the waters near the surface result in the decrease of their solvent powers for certain salts which are precipitated. Locally also the walls of the trunk channels contain minerals capable of acting as precipitating agencies. While these conditions exist to-day and a certain amount of waters are still circulating in the rocks of Nova Scotia and doing the work described, such circulation is a mere nothing as compared with the vast volume which went through the same cycle in the period immediately following the granite intrusion of the past.

Among the common precipitants of gold positively known to exist either as minerals in Nova Scotia rocks, or to have been carried in solution by ascending waters, are ferrous sulphate, ferrous chloride, iron pyrite, pyrrhotite, arsenopyrite, native arsenic, the organic matter including the graphite and carbonaceous matter of the upper rock formations, and even pure slate, which latter has the power of throwing down gold from certain solutions.

Experiments and Analyses.

For the most part these statements regarding the solvent and precipitating power of various substances have been confirmed by conducting a series of experiments and analyses on material personally taken by me in the Province of Nova Scotia, and including gold, gold ores, slates, quartzites, gangue minerals, mine water, and similar material. In other words, I have been able to prove that the conditions in Nova Scotia were formerly very favourable for the solution and ultimate precipitation of gold, silica, and other minerals and metals, and that even to-day in a vastly lessened degree these same processes are being carried on. During my investigations I made many analyses and assays of material from bedded veins, fissure veins, slates, and whin (quartzite), to determine their gold content as well as the other minerals therein, but space forbids my giving more than a few of the most interesting analytical results.

A sample of mine water was taken where it poured from a crevice of the roof on the 100-foot level, east drift, Holman mine, near the intersection of the Ross vein with a little fissure vein of less than half an inch in width, at which place a large quantity of coarse, nuggety gold was taken in December, 1909. The analysis of this water is as follows:

Analysis of Mine Water.

Results in parts per million.

Total solid matter in solution	272.
Solids volatile on ignition	47.5
Solids not volatile on ignition	224.5
Free ammonia	.05
Albumenoid ammonia	none
Nitrogen as nitrites	none
Nitrogen as nitrates	none
Chlorine	1.354
Bromine	trace
Sulphuric acid radicle (SO_3)	60.01
Hardness by Clark's test	110.
Lead	none
Manganese	trace
Cupric oxide	.12
Ferric oxide	8.
Aluminum oxide	1.
Silica	21.5
Calcium oxide	73.
Strontium	trace
Magnesium oxide	24.1
Sodium plus potassium oxides	35.3
Gold	trace

The gold was detected by evaporating several liters of the filtered water and submitting the residue to fire assay, and at the same time carrying on a check test on the reagents used which proved them to be free from gold. A confirmatory test for the gold consisted in dissolving the metallic particle obtained by fire assay in a drop of chlorine water, adding a drop of stannous chloride solution and obtaining a precipitate of purple of Cassius. Here we have a mine water actually carrying gold in solution. The iron in solution in the water reacted for ferric iron but not for ferrous iron. Where the water flowed from the wall it deposited a sludgy mass of red, hydrated iron oxide.

At a point on the wast plunge, 40-foot level, Holman mine, a sample of the same hydrated oxide of iron was taken beneath the B vein where it had been deposited in considerable quantity by a stream of water. Every possible care was taken to obtain this material free from rock or other extraneous matter, and after being carefully dried it was taken to Bangor and assayed. The assay showed in the dry material that gold was present at the rate of 67 cents per ton. The water content of the original was not determined dbut is estimated at about 75 per cent.

To prove the precipitating power that certain metallic sulphides, occurring in almost every bedded vein, have when brought in contact with gold-containing solutions, three different experiments are quoted here, all being on material from the Holman mine. The details of these experiments follow:—

(a) A sample of V vein ore was taken from the east superstope on the dome, and from this sample a piece

s selected which measured 32 x 25 x 6 millimeters d weighed 27 grammes. This piece was chiefly a ss of yellow and silver coloured metallic minerals ntaining several particles of visible quartz. It was ced in a beaker and over it was poured 25 cubic ntimeters of a solution containing 55.5 milligrammes gold in solution as the chloride. After 3 hours the ution was decolourized, showing that reduction of ld had taken place. The solution was filtered and nd free from gold by the purple-of-Cassius test. amination of the ore under the microscope showed had become coated with minute crystals of gold and th a brownish mass of amorphous gold, the crys- s being distributed equally over the surface of the artz, the yellow, and the silver coloured metallic nerals. The quartz, in addition to being coated with rstals of gold, was coated in places with a yellow film metallic lustre such as I have frequently observed on s of Nova Scotian vein quartz. Examination of the nple previous to immersion in the gold solution was de, and no such yellow films of crystals were then esent. This C vein ore is a peculiarly distinct ore, ferent from anything else I have observed in Nova otia. As exposed in the various workings of the lman mine, it is found to be a mass of yellow and ver coloured minerals with metallic lustre, appear- g as a solid metallic vein until on closer examination all particles of quartz are found scattered through but the quartz content is probably never over 35 r cent. In width the vein varies from an inch to e or six inches. Everywhere it is found to carry tter than $4 in gold value to the ton, but this gold nnot be extracted by direct amalgamation, requir- g instead some modification of the cyanide process. hile the C vein appears to be a bedded vein wherever has been exposed, it is so absolutely different in ap- arance from the many other bedded veins below and ove it that I am not prepared at present to discuss its igin. An analysis of the C vein ore made for Mr. lman by the Pennsylvania Salt Manufacturing Co., as follows:

Iron	19.00 per cent.
Arsenic	20.22 per cent.
Sulphur	20.75 per cent.
Insoluble	31.60 per cent.
Total	99.57 per cent.

The material they classify as insoluble is probably ostly quartz. In this vein iron pyrite and native senic make up the major portion of samples I have amined.

(b) For the next experiment I selected a partly ystalline pyrite of a silvery colour with striated ces. This was taken from a vein immediately be- ath the Ross vein in the face of the east drift, 100- ot level, Holman mine, the sample being from the ce, as it was in July, 1910. After pulverizing and ixing the sample a portion was taken for analysis, d another portion, weighing one gramme, was placed a beaker and over it was poured 25 cubic centimet- s of a solution containing dissolved therein 55.5 milli- ammes of gold as gold chloride. The solution was irred at five minute intervals, and at the end of 15 inutes it had become decolourized, while after filter- g and testing the filtered solution no gold was found maining therein. A copious precipitation of both ystalline and amorphous gold had taken place on e particles of powdered ore, as was shown by ex- amination under the microscope. My analysis of the ore is as follows:—

Specific gravity, 6.17.

Insoluble (mostly quartz)	1.45 per cent.
Sulphur	20.67 per cent.
Iron	35.18 per cent.
Arsenic	42.68 per cent.
Selenium	traces
Total	99.98 per cent.

Eliminating the insoluble matter shown by this analysis, the metallic minerals of the ore would appear to exist in about the proportion of 46 parts arsenopyrite to 4 parts pyrrhotite to 1 part pyrite.

(c) From a mass of nuggety gold, quartz and metallic sulphides submitted to me by Mr. Holman, and by him stated to have been a part of the rich ore taken from the Ross vein in December, 1909, I selected particles of the metallic sulphides as free as possible from both quartz and gold. This gold was taken from the intersection of a little fissure with the Ross vein, 100-foot level, Holman mine. The silvery coloured sulphides were powdered and mixed, a sample taken for analysis, and a gramme weighed out into a beaker. On this gramme of material was poured 25 cubic centimeters of a solution of 55.5 milligrammes of gold as gold chloride. The solution was stirred as described in the previous experiment and at the end of fifteen minutes was filtered and no gold found remaining in the filtered solution. The powdered particles of pyrites were covered by a precipitate of both crystalline and amorphous gold.

My analysis of this pyrite is as follows:

Specific gravity, 6.72.

Insoluble (mostly quartz)	2.40 per cent.
Iron	35.35 per cent.
Arsenic	41.76 per cent.
Sulphur	20.22 per cent.
Selenium	trace
Tellurium	trace
Total	99.73 per cent.

We have here the first recorded instances of the occurrence of selenium and tellurium in Nova Scotian ores. The presence of both was confirmed by applying the usually recognized decisive tests.

The metallic material from the Ross vein, whose composition is shown by the above analysis, may be assumed to exist in the proportion of 23 parts arsenopyrite to 3 parts pyrrhotite, as calculated from the analysis and eliminating the insoluble matter. The presence of pyrrhotite is easily demonstrated by passing a magnet over the powder which is attracted in a small amount.

Other tests, not quantitative, have been conducted where dilute solutions of gold chloride in water were poured into beakers containing Nova Scotian slates of the Halifax formation, some of these slates containing metallic sulphides imbedded therein, and others free from sulphides but containing graphitic or carbonaceous matter, and still other nearly pure slate. In all these cases the gold was entirely precipitated from solution, fairly quickly in the case of the materials first named and requiring several days in the case of the pure slate, but ultimately in each case the precipitation of the gold was complete.

Formation of Ore-shoots.

While it is, of course, possible that some of the bedded veins were direct trunk channels and derived their quartz and ore direct therefrom, it seems to me certain that a vast majority of the bedded veins are merely lateral branches which were filled by vein material diverted from the trunk channels into lateral openings, made in the thin strata of intercalated slate, into which the solutions from the vertical fissures were forced and in which were deposited silica, pyrite, arsenopyrite, and other minerals. Examination of the intersection of fissures and the bedded veins branching from them seems in many cases to show that they are contemporaneous in origin, while in other instances the fissures are clearly of later origin.

(To be continued).

MINERAL PRODUCTION OF THE PROVINCE OF QUEBEC DURING 1910.

Asbestos.

The returns received from asbestos producers show a total production of 80,605 tons of the various grades of asbestos, valued at $2,667,829 at the points of shipment. This is a substantial increase as compared with the shipments made in 1909, which totalled 63,965 tons, valued at $2,296,584.

These figures represent the actual shipments made, and they are this year considerably less than the output, as a great deal of asbestos of all grades was reported as stock on hand on December 31st. As may be seen by the table given below, this stock on hand amounted to 41,159 tons, which, valued on the same basis as the shipments, amounted to $1,921,923.

The activity of asbestos mining was very notable during the first seven months of the year. The mines were working night shifts as well as day shifts, and most of the mills were producing to their full capacity. Unfortunately the demand did not keep pace with the increased output, and as a result the market became congested, prices dropped and the stocks on hand increased. Towards the end of the year several of the mines discontinued mining operations and a period of stagnation ensued. That this state of affairs is only temporary is shown by the past records of the asbestos industry. Periods of over-production and consequent depression have been noted before, and these have always been followed by periods of healthy growth.

	Shipments		Stocks on hand Dec. 31.	
	Tons	Value	Tons	Value
Crude No. 1	1,817	$ 471,649	1,703	$ 447,227
Crude No. 2	1,612	196,382	3,181	440,884
Mill Stock No. 1	10,313	627,635	4,938	313,053
Mill Stock No. 3	44,793	1,141,374	24,417	621,065
Mill Stock No. 3	22,070	230,789	6,920	99,694
	80,605	$2,667,829	41,159	$1,921,923
Asbestic	24,711	17,612		

The value of the asbestos shipments made during the year 1910 is the highest recorded to date. The previous banner year was 1908, when it reached $2,551,596.

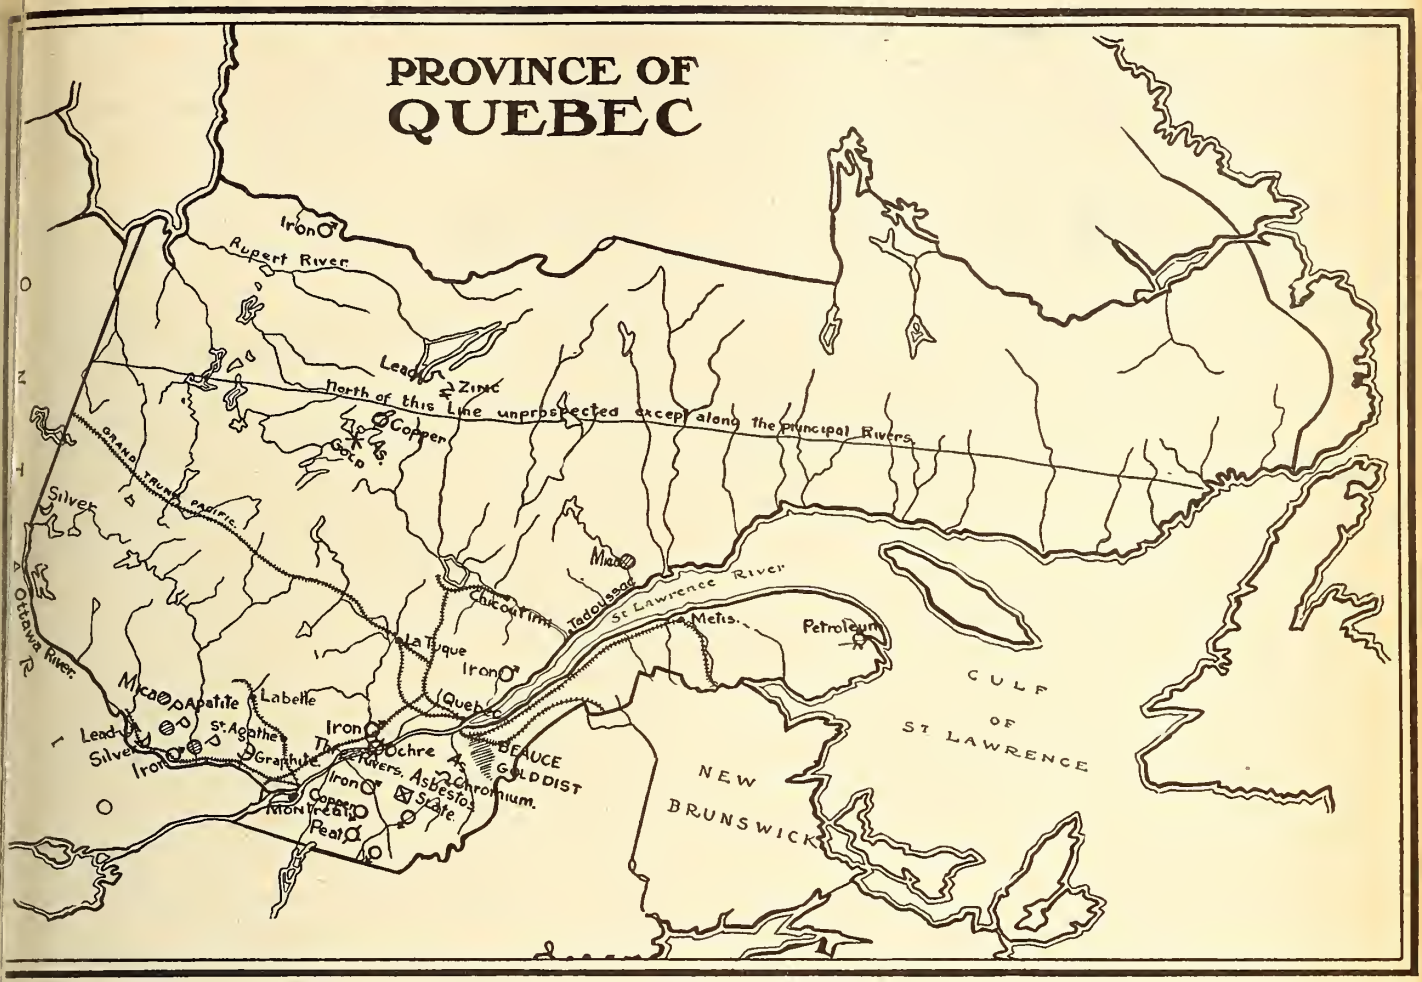
The following table illustrates the growth of the asbestos industry during the past decade:

Year	Tons.	Value
1900	21,408	$ 719,416
1901	33,466	1,274,315
1902	30,634	1,161,970
1903	29,261	916,9
1904	35,479	1,186,9
1905	48,960	1,476,4
1906	61,675	2,143,6
1907	61,985	2,455,9
1908	65,157	2,551,6
1909	63,965	2,296,3
1910	80,605	2,667,8

The returns which we received from the producers show that a quantity of 2,035,705 tons or asbestos bearing rock was quarried during 1910. Of this rock about 25 per cent. is waste, which goes to the dump without treatment as being too lean in asbestos for milling. Shipments of asbestos during 1910 and stocks on hand at the end of the year totalled 121,755 tons, valued at $4,589,756 at the prices prevailing during the year. To arrive at the output, we may substract the stocks on hand at the end of the previous year 1909, which, according to the Federal Mines Branch, amounted to 20,921 tons. These figures leave a total extraction during 1910 of 100,837 tons of asbestos from 2,035,705 tons of rock mined or from about 500,000 tons of rock milled.

It must be understood that these figures are averages of totals. In the case of individual mines the figures of extraction, may diverge considerably from these averages.

In last year's report, attention was drawn to some of the advantages which were likely to ensue from the amalgamation of individual asbestos properties into large corporations. One of these advantages was that it would be easier to establish a standard classification of the various grades of asbestos. The importance of this point can hardly be exaggerated, for it is quite likely that one of the reasons which militates against a more rapid extension of the uses of asbestos and contributes to the dulness of the market, comes from the fact that at present there is a lack of uniformity in the grading and classification of the various products of the asbestos mills. Each individual producer has its own grades and marks which can only be sold to manufacturers and consumers by submitting samples. In the classification which we have adopted in the short table given above, we have followed the Federal Mines Branch, based on value per ton of the product. Crude No. 1 represents asbestos quoted $200 a ton and over. Crude No. 2 under $200. Mill stock No. 1, is the product of the mills of a value of $45 per ton and over, No. 2 between $45 and $20 inclusively, and No. 3 under $20, but individual items of these groups vary widely between the limits assigned and the classification is arbitrary in the extreme. For instance, under mill stock No. 1,



have grouped asbestos representing not less than 17 grades according to prices, which are designated by the following marks: "No. 1," "No. 1 A," "No. 2 A," "No. 2 B," "A," "C," "D," "M," "X," "XXX," "Long," "Special Spin."

Similarly in Mill Stock No. 2 there are ten different prices and the products are classified as: "A," "3 B," "B," "C," "E," "No. 2," "No. 3," "X," "XX," "OO," "OK."

Whereas in Mill Stock No. 3 we get: "C," "CC," "F," "N," "D," "E," "Short F," "No. 3," "No. 4," "No. 5," "X," "XXX," "XX paper."

As may be imagined, these various designations which have no connection between themselves, must to a great extent puzzle and bewilder the buyers, and selling by samples must necessarily be resorted to.

This subject of classification is very important, and it is thought that great benefits to the industry would be derived from a better standardization of the various grades. But, of course, such a result can only be achieved through a concerted action on the part of the producers.

Returns of shipments of asbestos were received from 13 companies, as follows:

Amalgamated Asbestos Corporation,	Thetford Mines.
Asbestos and Asbestic Co., Ltd.,	Danville.
B. & A. Asbestos Co.,	Robertson.
Bell Asbestos Mines,	Thetford.
Belmina Consolidated Asbestos Co.,	Chrysotile.
Berlin Asbestos Co,	Robertson.
Black Lake Consolidated Asbestos Co.,	Black Lake.
Broughton Asbestos Fiber Co.,	East Broughton.
Frontenac Asbestos Co.,	East Broughton.
Jacobs Asbestos Mining Co.,	Thetford.
Johnson's Company,	Thetford.
Ling Asbestos Co.,	East Broughton.
Robertson Asbestos Mining Co.,	Thetford North.

Copper.

The copper bearing ores now produced in the Province of Quebec come from the cupriferous pyrite deposits of the Eastern Townships. This ore is primarily used in the manufacture of sulphuric acid and the cinder is sent to the copper smelters for the extraction of the copper.

The production of ore in 1910 was the lowest recorded since 1904, being 24,040 short tone, a decrease of 11,060 tons as compared with the previous year.

Year	Tons	Year	Tons
1893.....	64,960	1902.....	31,938
1894.....	47,132	1903.....	26,481
1895.....	42,470	1904.....	23,729
1896.....	47,730	1905.....	28,644
1897.....	41,233	1906.....	32,527
1898.....	39,968	1907.....	29,574
1899.....	43,599	1908.....	26,598
1900.....	37,791	1909.....	35,100
1901.....	22,732	1910.....	24,040

The Eustis mine was the principal shipper. This mine, which is situated at Eustis, on lot 2, range IX., Township of Ascot, nine miles south of the eity of Sherbrooke, began operations as far back as 1879. The ore occurs in lenticular masses, the sizes of which greatly vary in width, between a few feet and 75 feet. The lenses are usually conneeted by narrow veins which sometimes pinch down to an inch or less.

The length of the main slope of the Eustic mine is now over 3,000 feet long, on an angle of 40 degrees. The head of the slope is reaehed by a rock tunnel, 1,000 feet in length.

The orc is concentrated in a mill which is situated 3,000 feet from the top of the slope, and it is shipped mainly to Boston, where it is used in the manufacture of sulphuric aeid. The copper bearing cinder is then sent to West Norfolk, Virginia, where the Eustis company has a smelter in which are also treated some of the Virginia ores.

Some shipments are also made to the Nichols Chemical Company, at Capelton, Que.

It is interesting to note that the manager, Mr. Adsit, saved this year an appreciable amount of copper by the simple process of passing the mine water over scrap iron.

We reeord this year comparatively important shipments of eopper and sulphur ore from the McDonald mine, at Weedon, on lot 22, range II., Weedon, which has been under aetive development work for two years. This mine is worked by the East Canada Smelting Company.

The ore of this deposit eonsists of iron pyrites and chalcopyrite, occurring as lenticular masses, in more or less altered schists. Thc oceurrenee resembles closely that of the deposit which is worked at the Eustis mine. The main body of ore has been proved to be over 500 feet long, and to have a maximum width of 50 feet. It is likely that further development work will reveal other lenses.

The lens which has been developed has the same strike as the eounty rock, N. 40 deg. E., and dips to the S.E. at an agle of 45 deg.

The deposit has been developed to a depth of 110 feet by means of two shafts, 100 and 110 feet deep respectively. The latter is now being sunk to the 200 feet level. More than 700 feet of levels and crosscuts have been driven.

Shaft No. 1 is equipped with a 15 h.p. hoist, which can handle 70 tons per shift from a depth of 400 feet. The boiler equipment consists of two horizontal boilers and one vertical boiler, aggregating 200 h.p. The compressor plant comprises two Rand straight line eompressors eapable of running 8 drills.

Substantial shipments were maed to the Capelton Chemical Works of ore said to average 44 per cent. sulphur and 5½ per cent. copper.

The Albert mines in the same district, which shut down some two years ago, have not been reopened. The workings are now full of water. Some prospecting work was done on several of the old mines, but nothing of note has resulted.

A. O. Norton eontinued his prospeeting and development work at the Suffield mine, but no ore was shipped. The deposit worked here is a low-grade silicious ore, which consists of a mixture of chalcopyrite, pyrite, and a little bornite. The shaft is 400 feet deep, and there are 700 feet of drifts at various levels. The surfaee plant consists of a steam boiler of 100 h.p., a hoisting engine of 50 h.p., and a 4 drill air eompresso

Mr. Norton has also reopened the Marrington mi on lot 6, range V., Aseot Township, and did some pro pecting there with the help of a small 20 h.p. boil and hoisting engine. The drilling was done by han The shaft is 265 feet deep, and there are 500 feet drif ing.

At the Hepburn mine, lot 7, range IX., Aseot Tow ship, the Eustis Mining Company did some work of r opening and prospecting.

Thc Ascot mine, lot 8, range IX., Ascot Townshi was prospected by Mr. John McCaw, of Sherbrook for the East Canada Smelting Company, but no or was shipped.

On lot 24, range V., of Cranbourne, a little work wa done on a deposit which is said to contain bornite an chalcopyrite.

In the Beauce district considerable prospecting wor was done on two deposits in the vicinity of St. Fra cois. These deposits consist of quartz veins and lense cutting eruptive rocks largely serpentinized and co taining chalcopyrite and a little bornite.

In the fall of 1909 work was begun on the erectio of a small copper smelter at Actonvale, by Mr. P. Te reault, of Montreal. The intention was to treat th ore from the dumps of the old Actonvale mine, as wel as to do some custom work. The plant was complete and the furnaee blown in during the spring of 191 It consists of an Allis-Chalmers water-jacketed fur nace, of a capacity of 80 tons of ore a day; one Roo blower of a capacity of 6,600 c.f. of air per minute one 80 h.p. boiler and other accessories. After a shor run the operations were diseontinued to make altera tions. The plant is still in the experimental stage.

The old Aseot mine was unwatered and some samp ling was done.

On the whole, the copper industry of the Eastern Townships was not very active during 1910, owing in a measure to the low price of the metal which prevailed during the year. But other reasons also militate against an active resumption of work. One of the main causes, as remarked by Dr. Wilson, who studied the question for the Federal Mines Branch in 1909, is the attitude assumed by the majority of owners of undeveloped and unexplored prospects, who usually have high pretentions and disproportionate ideas as to the value of sueh prospects. The owners will not, as a rule, assume the risks of development, and yet ask prohibitive priees for their properties, and often are not even willing to give facilities to have them tested. Instances have come to our notice in whieh thousands of dollars are asked for mere eopper-bearing outerops, on which no work beyond a few days' stripping have been done.

Mr. Samuel Owen Greening, for 34 years the head of the well-known B. Greening Wire Company, Limited, died on the morning of August 31st, at his residence in Hamilton. The late Mr. Greening was born 64 years ago in Manchester, England. He came to Hamilton in 1856, in which year his father founded the company. Under the son's management the business grew to its present large dimensions.

Mr. Greening was one of the very best types of citizen and business man. He weilded a large, though quiet, influence for good.

FLUORSPAR

By Ernest F. Burchard.*

Fluorspar.

ommercial Value.—Fluorspar is a mineral of rela- ly low value as compared with metallic ores ed under similar conditions. Under the most fa- rable conditions, therefore, the margin of profit never be expected to be large, and it requires ex- tionally good management to conduct any spar ing operations profitably, especially in the west- states. In 1910 there were 69,427 short tons of estic fluorspar, including gravel, lump, and ground ieties marketed in the United States at an average ue of about $6.20 per short ton. Of this total, 61,- short tons were sold as gravel and lump spar, at average value of $5.58 per ton at the mines, and 91 short tons were sold ground, at an average value $10.72 per ton, f.o.b. cars.

Uses and Requirements of fluorspar—Fluorspar is d in the manufacture of glass and of enamelled and itary ware, in the electrolytic refining of antimony l lead, the production of aluminum, the manufac- e of hydrofluoric acid, and in the iron and steel ustries, in which it is used as a flux in blast fur- es and in basic open hearth steel furnaces. It is imated that about 80 per cent. of the American orspar output, mainly in the form of gravel spar, consumed in the manufacture of basic open hearth el. The use of fluorspar is increasing in practically of these industries. The western market for fluor- ar is more limited than that of the central and east- n states, but it is nevertheless increasing. Recently e iron and dsteel works at Irondale, Washington, d in Shasta County, California, have been enlarged. Supplies of spar mined in the west have heretofore t been sufficient to supply the western market for re than a few months at a time. This has been due several conditions, the most important of which is at most of the western spar thus far produced has t been of as high a grade as that produced in the inois-Kentucky district. Fluorspar for iron and eel making should carry at least 85 per cent. calcium oride and preferably it should be purer. For most her chemical uses it should contain from 95 per cent. 98 per cent. calcium fluoride.

Production.

The total quantity of domestic fluorspar reported the Survey as marketed in the United States in 10 was 69,427 short tons, valued at $430,196, as com- ared with 50,742 short tons, valued dat $291,747, in 09, an increase in quantity of 18,685 short tons, and value of $138,449. This increase represented nearly 7 per cent. of the quantity and 47 per cent. of the alue of the production of 1909. The production in 10 was the largest ever recorded. The average alue per ton for the whole country, considering all rades of fluorspar, was about $6.20 in 1910 as com- ared with $5.75 in 1909. This value represents the elling price on board cars at railroad or water ship- ing points, and with reference to the product from olorado, New Mexico, and Kentucky the price re- orted for much of the spar includes the cost of a ng wagon haul—$1.50 to $3 a ton. In Illinois the principal producing mines are near river transportation, and the cost of long wagon hauls has not entered into the reported value of the fluorspar.

Fluorspar was produced in 1910 in Illinois, Kentucky, New Mexico, and Colorado in the order named, each state, except Colorado, reporting an increased production. The product of Colorado and New Mexico has been classed as gravel spar, although much of the New Mexico product was equal to the grade of lump spar. Both Illinois and Kentucky produced gravel, lump, and ground spar.

In 1910 Illinois produced a total of 47,302 short tons of spar, valued at $277,764, or $5.87 per short ton on board cars. The gravel spar amounted to 35,477 short tons, valued at $178,880, or $5.04 per ton. The sales of lump spar in Illinois were 6,151 short tons, valued at $38,415, or $6.25 per ton. The ground spar sold in this state amounted to 5,674 short tons, valued at $60,469, or $10.66 per ton. Kentucky reported total sales of 17,003 short tons of spar, valued at $124,574, or an average price of $7.33 per ton, distributed as follows: Eleven thousand four hundred and fourteen short tons of gravel spar, valued at $75,823, or $6.64 per ton; 2,972 short tons of lump spar, valued at $20,359, or $6.85 per ton; and 2,617 short tons of ground spar, valued at $28,392, or $10.85 per ton. Colorado and New Mexico together produced 5,122 tons of gravel spar, valued at $27,858, or $5.44 per ton. The total stocks of fluorspar reported on hand in all the states December 31, 1910, were less than 2,000 tons.

Trade Conditions.

The demand for American fluorspar at Pittsburg, Birmingham, and other cities during 1910 was apparently greater than the capacity of the mills operating in the Illinois-Kentucky district. Prices advanced a little, but not enough to pay many of the smaller companies for operating, and consequently many of them were idle in both states. As a consequence of the increased demand, large stocks left over from previous years were practically cleaned up in localities within reach of transportation lines. Many steel plants purchased reserve stocks in anticipation of possible future scarcity of fluorspar. The steel plant at Pueblo, Colo., took the whole output of the Colorado and New Mexico producers in 1910, besides some spar from Illinois, but did not consume the total quantity purchased. Although, as noted on another page, the imports were exceedingly high, notwithstanding the import duty of $3 per ton imposed in 1909, the market for domestic spar does not appear to have been seriously affected by the quantities of fluorspar imported.

The conditions in the open hearth steel industry have a most direct bearing on the production of fluorspar, since the greater part of the gravel spar produced is used in the manufacture of basic open hearth steel. The increase in the quantity of basic open hearth steel in 1910, as compared with 1909, amounted to 1,874,857 long tons, or nearly 14 per cent. The following table* shows the production of open hearth steel during the last three years

*Abstracted from advance chapter Mineral Resources of the United States.

*Ann. Statis. Report Am. Iron and Steel Association, Philadelphia, Pa., July 25, 1911.

Production of open hearth steel in 1909-1910, in long tons.

	Basic.	Acid.	Total.
1908	7,140,425	696,304	7,836,729
1909	13,417,472	1,076,464	14,493,936
1910	15,292,329	1,212,180	16,504,509

Imports.

Before August, 1909, fluorspar was imported into the United States duty free, and the full statistics of importation were not given before that date. Large quantities of gravel spar produced at a low cost from the tailings of lead mines and from the gob in abandoned mines in England have been shipped to this country as ballast at a very low freight rate. The material thus produced is high in silica and is almost entirely consumed by open hearth steel makers. Before 1909 spar from England competed with American fluorspar as far west as Pittsburg and practically fixed the market price at that point. In the Lehigh and Susquehanna valleys of Pennsylvania and other localities near the Atlantic seaboard English fluorspar can yet be advantageously purchased under present conditions, and large quantities are consumed annually in the open hearth steel furnaces. The imports of fluorspar entered for consumption into the United States in 1910 were 42,488 short tons, valued at $135,-152, as compared with 6,971 short tons, valued at $26,377, in 1909. The value assigned to the material in 1910 was $3.18 per ton, as compared with $3.78 in 1909.

Mining and Milling Developments.

Illinois.

The principal developments during 1910 were confined to the properties of the Fairview Fluorspar & Leadd Company at Fairview Landing, and the Rosiclare Lead and Fluorspar mines, at Rosiclare. At other properties there was some prospecting by drill and a little mining, but the greater part of the output came from the two companies named.

At the Fairview mine four shafts produced ore, including one mining the "blue" vein. The deepest shaft (or steep incline) was reported 503 feet deep in the spring of 1911 and the deepest working level was 475 feet below the surface. At this level considerable calcite is encountered, either mixed with spar or else constituting nearly the whole vein. The vein is irregular in width, ranging from pinches 18 inches wide to swellings 25 feet wide. The spar bodies exhibit irregular outlines within the vein, and range from a few feet to 22 feet in width. One of the largest bodies was encountered at the 400-foot level. A new shaft has recently been sung to a depth of about 320 feet, with levels at 100 feet, 235 feet, and 295 feet from the surface. The "blue" vein shaft was at that time reported to be down 120 feet and to show 4½ feet of ore at the bottom. An important production was stoped from this vein in 1910. The main workings of the Fairview and the Rosiclare companies are approaching one another and are believed to be on the same vein. The mill at Fairview has recently been improved and enlarged, particularly with reference to the facilities for the preliminary picking and the final jigging of the spar. The jigs are reported to consist of a 5-cell rougher, a 6-cell cleaner, and a 5-cell finisher. The capacity of the mill is reported at 200 to 250 tons of cleaned spar per 10-hour shift and the storage capacity at about 3,000 tons. Spar is loaded directly at the mill into standard-gauge cars, which are moved over a short line to the landing on [illegible] River and towed on barges to the Illinois Central Railroad at Golconda.

At Rosiclare the mining method has been changed from underhand to overhead stoping. Only one shaft is operated here, and the lowest level was 235 [illegible] below the surface in April, 1911. In July it was reported that the shaft had been sunk to 275 feet and was planned to be sunk to a depth of about 335 [illegible] where a new level will be established. Local pinching and swelling is characteristic of the vein, the width ranging from a few inches to 22 feet. In places the vein is found to carry almost entirely calcite, but there are large quantities of good ore still available at the lowest level, in both directions from the shaft. A new steel and concrete mill, entirely fireproof, has been built at Rosiclare, designed to reduce 500 tons of crude ore per day. The shaft has been reconstructed and consists of three compartments, two of which for hoisting, are 5 feet 5 inches by 4 feet 4 inches, and one is a pump compartment, 5 feet 5 inches by 3 feet 8 inches. The mill consists of three large buildings. The sizing and sorting building, with the shaft at the south end, stands in the middle, with the power house and grinding building to the west and the concentrating building, or jig house, to the east. All the buildings are approximately 90 feet long. The middle building is 20 feet wide at the base, and the head frame stands 84 feet high. The two other buildings are 36 feet wide and stand 30 feet to the eaves. The alleys between the middle building and the two others buildings are 14 feet 6 inches wide.

From the mine the spar is hoisted to the top of the mill in steel cars having a capacity of one ton each. The spar is dumped on steel grizzlies having 2½-inch spaces. The grizzlies are inclined toward two 24-inch steel apron conveyers. From the oversize No. 1 lump spar is picked and thrown on the conveyers. The common spar not passing the grizzly is shoveled into a No. 5 gyratory crusher. The total capacity of the grizzlies is about 100 tons of material. The material passing the grizzly and the crusher feeds down into two 150-ton steel bins on the floor below. These bins feed into two shaking screens on the floor next below. These screens have steel frames 17 feet by 2 feet 9 inches, with bottoms of heavy wire with meshes about ½-inch by 1⅛ inches. The lump spar is delivered by the apron conveyer to a rotary drier 25 feet long by 36 inches in diameter, which is supplied with hot air from the top of the boilers. The ore falls from the drier on a "butterfly," which diverts the material as desired, either into a bin for No. 2 lump spar or through a drying tower into a No. 3 crusher. The No. 2 lump spar may be drawn directly from the bin, barreled, and shipped. The No. 1 spar passes through the No. 3 crusher, which feeds by gravity into a grinding mill. This mill discharges through a 30-mesh, 30-wire screen into a screw conveyer, which moves the ground spar to four storage bins. Each bin feeds into a barrel which stands on a packer. The barrels of ground spar weigh 550 to 610 pounds when filled. The capacity of this packing room is about 10 barrels per hour, or 30 tons a day.

From the shaking screens the undersize is carried by water through a 9-inch pipe to the jig house, and the oversize of the screens falls on a picking belt, at which 9 to 15 men may work. On this belt separation is made by hand of the larger fragments of lead and zinc ore, calcite, waste, and fluorspar. Lump spar can thus be picked, if desired, in order to increase the

tity secured by picking on the grizzly above. The e and calcite are thrown directly to chutes lead- to their respective bins, while the lead and zinc pass through short chutes to separate troughs below the picking belt, and are moved by a double ing conveyer to separate 13-inch disk crushers. overrun of fluorspar from the picking belt passes he opposite direction to a 24-inch disk crusher. lead and zinc ores discharged from their respec- disk crushers are carried through pipes across to ator jigs in the jig house. From the 24-inch disk her the spar and the fine lead and zinc ores are into a bin. This bin feeds into the same service which receives the undersize from the shaking ens. This service pipe crosses to the jig house and s into a 5-celled rougher jig. The ore from the her jigs goes to a cleaner jig having six cells. vision is made for catching the lead from the righ- ig and for taking care of the tailings. Between rougher jig and the cleaner jig are sand crushers several pumps, and the system is very flexible. lead and zinc ores coming from the 13-inch disk shers are treated by two 4-celled pulsator jigs, hav- a set of laboratory rolls. Of the ore at present sidered normal about 90 per cent. consists of con- trates of fluorspar, galena, and sphalerite (zinc de). The galena recovered constitutes about 1 cent. of the concentrates, and the sphalerite still . It is planned to treat a large quantity of tailings m the oil mill, of greater richness than those now duced, as soon as the new mill is working perfect- The milling of fluorspar offers rather difficult blems, for unlike most ores, the bulk of the pro- t must be saved, and the waste which must be minated constitutes relatively a small percentage. addition, the separation of the lead and the zinc m the fluorspar is difficult, particularly where such all percentages of the former minerals are present, it is essential that they be almost completely re- ved, since the presence of sulphide ores renders the orspar of little value as a flux in steel making. reover, if the separation can be completely and eco- mically effected, the lead and zinc ores recovered terially assist in paying the expense of cleaning the e.

Under normal conditions about 57 men are em- yed overhead, including office force and superin- ndents, and about 48 men underground. When vis- d in April, 1911, this mill had not been entirely mpleted, and its capacity had not been demonstrat- . It was expected, however, that its capacity would r exceed any other mill built to treat fluorspar and sociated ores. The product of this mill is carried Ohio River over an electric tramway 3,300 feet ng, and is then loaded on barges and towed to Shaw- etown, Ill., Evansville, Ind., or Golgonda, Ill. The er is generally closed by ice for a short period in inter, and in very dry summers the water may be- me too low for transportation. For this reason an deavour is made to maintain sufficient stocks of ar from the Rosiclare mines at the railroad in Shaw- etown to provide for shortages caused by interrupt- l shipments.

New Mexico.

Only recently has fluorspar been found in New exico in sufficicit quantities for exploitation. The merican Fireman's Mining Company, of Kansas ity, Mo., in prospecting for metallic ores on property tuated 10 miles northeast of Deming, Luna County, N. Mex., has opened a number of veins of fluorspar which give promise of containing nearly if not quite sufficient spar to supply the western market for several years.

Location.—The fluorite occurs on the flanks of a small ridge called "Fluorite Ridge," one of the foothills of Cooks Range, 10 miles northeast of Deming. The most promising prospects have been made in two localities separated by a distance of about 1¼ miles. One of the localities is at the extreme southeastern base of the ridge on a gentle rise about 400 feet above the plain; the other well up the south slope of the ridge about 900 feet above the plain. Deming lies in a nearly flat valley covered by desert deposits, with Cooks Range 10 to 15 miles northeast and the Florida Mountains 10 miles or more southeast. The fluorspar deposits are most easily reached by a 10-mile drive from Deming, but the product is shipped from a siding, on the Atchison, Topeka & Santa Fe Railway, called Mirage, 5½ miles southeast of the prospects.

Geologic Relations.—Fluorite Ridge consists of a central mass of monzonite pohphyry which has intruded strata of Paleozoic and Mesozoic age, chiefly Ordovician limestone and Carboniferous and Cretaceous sandstone, quartzite, and conglomerate. The dips of the sedimentary strata on the south and west sides where the fluorspar is found are very steep, or vertical, and masses of the strata have not only been tilted up by the intrusive action, but folded into the intrusive rock. The base of the ridge is surrounded by an agglomerate consisting of angular masses of ondesite embedded in tuff. Some thin dikes of balast cut the agglomerate, and unconsolidated "desert fill" overlies it at a short distance from the base of the ridge.

Occurrence and Character of the Fluorspar. — The fluorspar occurs in veins, cutting and altered monzonite porphyry. Certain of the veins fill fractures in the rock along which there has been movement in both a vertical and a horizontal direction, but between the walls of some fissures there has not been noticeable displacement. The rock at the southeast base of the ridge is cut by two or more groups of approximately parallel veins. As shown by the openings that have been made, there appear to be at least five or six distinct veins in each group. One group of veins strikes N. 17 deg. E. to N. 27 deg. E., and the other strikes N. 6 deg. E. to N. 18 deg. W., and still other veins were observed to strike at various angles between these limits. The veins are nearly vertical or dip steeply in a southeast or northeast direction. The vein material is mainly fluorite mixed with a little quartz. Where the veins are partly siliceous they resist weathering slightly better than the surrounding porphyry, and therefore leave broken traces on the surface. At the surface the fluorspar in places is altered to calcium carbonate. The thickness of the veins as shown by surface cuts and by prospect pits and shafts ranges from a few inches up to 12 feet or more, but it is generally from 2 to 5 feet. The structure of the veins is in places distinctly banded; in other places the vein appears to consist mainly of a mass of crystalline spar, showing no banding, but carrying pockets of quartz. Brecciation of the vein by which large fragments of the wall rock have been included is not uncommon. The walls of the veins where open to any considerable depth are found to be smooth in places, but they are rarely smooth or regular for many feet, and the wall rock is generally much decomposed.

At the locality on the south slope of the ridge only

one set of veins, striking in a northwesterly direction, was observed. They stand nearly vertical or dip steeply toward the northeast. These veins had been opened in only two or three places in 1910, and the maximum width observed was only about 4 feet, not all of which was filled by spar. The veins cut monzonite porphyry, as at the first locality, and were observed to outcrop at intervals in the direction of strike for a distance of one-quarter mile.

Developments—At locality No. 1 the American Fireman's Mining Company opened in 1909 a number of veins by means of shallow cuts, and sank several test pits to depths of 6 to 12 feet and two shafts to depths of about 80 feet. In all, about 20 openings had been made up to August, 1910. A triangular area about one-fourth mile wide at base from northwest to southeast, and about one-third mile from northeast to southwest, has been shown to carry productive veins of fluorspar. The surface of the area slopes gently to the southeast. At the main opening the vein strikes N. 17½ deg. E. to N. 22½ deg. E. and dips 65 deg. to 70 deg. toward the southeast. The vein had been opened to a depth of 75 or 80 feet in August, 1910, and had been worked for a distance of about 100 feet on the strike. The thickness between the walls of the vein measures 4 feet to 12½ feet, the irregularities being due to pinching together of the walls in places. The strike of the vein is apparently slightly sinuous, according to the irregularities in the walls, but there are no evidences of movement between the walls. The rock inclosing the vein is altered to a reddish colour so far as observed, and although the vein walls are smooth and clean in places, in other places there is interpenetration of vein and wall material.

The fluorspar is principally of a light-green shade, but there is some purple spar present, especially near the margins of the vein, and some quartz is present in pockets and thin stringers scattered throughout the mass of spar. The spar is mined from several levels and milled down through chutes to the lowest level, from which it is hoisted in buckets up the shaft to the surface. A steam hoist was being installed in Aug. 1910. On the strike of the opening, less than 100 yd. north of the shaft, an open cut and shallow burrow showed a promising vein of spar with a fork extending in a northwest direction. These veins and another a few yards to the west are the nearest to the limestone mass, which lies 35 yards or more to the west. So far as could be ascertained, none of the veins extend into the limestone. The greater part of the spar that has been produced in this region has been taken from the shaft just mentioned.

Grades of Western Fluorspar.—None of the spar that has been mined in Colorado and New Mexico has been cleaned in any way except by hand. Mechanical concentration would improve the grade of the Colorado spar greatly, but none of the fluorspar prospects in Colorado have proved of sufficient richness to warrant the installation of washing plants. In certain places water is available, but in others the problem of finding water would be difficult. The Colorado product has never averaged quite high enough in grade fully to satisfy purchasers or to command a price satisfactory to producers. With regard to the deposit near Deming, N. Mex., there is little necessity for washing, but such a process would not be at all possible on account of thescarcity of water. Supplies of water for men, teams, and hoisting engine have to be hauled from a well more than 4 miles distant on the road to Deming. There is little probability that a supply could be obtained by drilling anywhere near the fluorspar deposits on account of the nature and structure of the underlying rocks.

Analyses.—The following table gives analyses of gravel fluorspar from Mirage, N. Mex., generally in carload lots used in basic open hearth steel furnaces and analyses of spar from Colorado, Illinois, and Kentucky, made on a similar basis, are given for comparison.

From these analyses it will be seen that the spar hipped from Mirage, N. Mex., is of an exceptionally igh grade, considering the fact that it has not been ashed and cleaned as has the Illinois-Kentucky pro-uct.

Cost of Production.—The mining of the fluorspar ear Deming is done almost wholly by contract. Mexi-an labour is employed, and miners earn about $1.50 er day. Mining the spar costs per ton $1.75, plus 5 cents for incidentaly expenses, and haulage to the ailroad costs $1.50, making a total cost of $3.50 per on dumped into cars. The spar in 1910 was selling t $5.25 per ton on the cars, based on at least 90 per ent. calcium fluoride, and the freight from Mirage to ueblo, paid by the purchasers, was $2 per ton. Ac-ording to contract a penalty of 20 cents per ton is leducted for each per cent. that the spar falls below 0 per cent. calcium fluoride, but no premium is paid nless it carries more than 95 per cent. calcium fluor-de, when each unit brings 20 cents more per ton. The equipment for mining the spar is simple, the larg-est items of expense being the small steam hoist sta-tioned at the deepest working, and the several teams necessary to haul the output. Small store buildings and machine shops have been built at both places where the spar was being developed. The labourers live in tents, and work can be carried on the year round. From the opening of these deposits in the summer of 1909 to the close of 1910 nearly 5,000 tons of fluorspar had been shipped, averaging 92 per cent. calcium fluoride.

Conclusions.—The exploration for and development of fluorspar deposits under present conditions in the western states can not be said to offer attractive pro-fits; nevertheless the market for fluorspar is growing, and where deposits are found so situated that the freight rates do not hold down the price to a profitless level and the cost of haulage does not further wipe out all chances of gain, the development of such deposits should be encouraged.

THE PREVENTION OF ACCIDENTS IN MINES.

In Queensland and New South Wales the Acts for he prevention of accidents in mines provide that in nines employing more than ten men below ground the nining inspector shall be the holder of a first-class nine-manager's certificate, and be over thirty years f age. The Queensland Act states: "Wherever any nining inspector shall have inspected any mine or nachinery he shall enter in a book, to be kept on the nine or works for the purpose, his opinion derived rom such inspection of the actual condition of the nine and machinery at the time of such inspection, nd he shall also record what alterations or require-nents he thinks necessary." This is doubly useful, as it keeps the inspector up to the scratch and allows the manager to know at once the position, while should an accident occur it shows that the mine was in a safe condition at the time of the inspection. This record is also useful for reference purposes on any subsequent visit of an inspector. There is another use-ful regulation in the Queensland Act, namely, that the manager of every mine has once a week to sign a state-ment in a book kept for the purpose, that during the week he has at least once visited every working face in the mine, and he has to state whether conditions were safe or otherwise. In big mines this regulation will keep the manager up to his work and prevent too much dependence being placed on the foreman.

As to the storage of explosives, the Queensland Act states that: "Detonators for blasting shall be kept on the surface of the ground, in a covered box placed in a separate magazine. No more than 100 detonators shall be kept underground in any level at one time, and these shall be kept in a covered box in a separate drive or chamber and only taken out in such quanti-ties as required for immediate use. Detonators shall not on any pretence whatsoever be placed near any travelling road, pass or working face." The Austra-lian Acts require the mine manager to supply the Mines Department with a copy of the working plans of the mine, and are very particular about the tensile strength of hoisting ropes, etc. In the case of fatal accidents no work other than that required to save life shall be done, nor the conditions altered in any way until the inspector has had an opportunity of examining the position.

Preliminary Programme of the National Mine Safety Demonstration

Pittsburg, Pa.

October 30 and 31, 1911.

Board of Managers.

H. M. Wilson, representng United States Bureau of Mines; Dr. M. J. Shields, representing American National Red Cross Society; S. A. Taylor, representing coal operators of the United States; Francis Feehan, representing United Mine Workers of America; John Laing, representing the State Mine Inspectors; Thos. B. Dilts, representing Industrial Department of International T. M. C. A.

General Committee.

Chairman, H. M. Wilson; Mine Rescue and First Aid, J. W. Paul; Arsenal Demonstration, Clarence Hall: Experimental Mine, L. M. Jones; Programme, Lauson Stone; Reception, J. C. Roberts; Ushering, J. K. Clement; Secretary, C. S. Stevenson.

United States Bureau of Mines.

Arsenal Grounds, 40th and Butler Streets, Pittsburg.

October 30, 1911.

Address of welcome, 9 a.m., Director J. A. Holmes, Bureau of Mines.

Event No. 1—(Continuous from 9.15 a.m. to 12M., with interruptions for Events 2 to 6.)

Building No. 10—Electrical laboratory, showing the effect of breaking lighted incandescent lamps which are surrounded by an explosive mixture of gas and air.

Building No. 13.—The foundry cupola in operation and method of securing gas samples and taking temperature measurements from different zones in the coke bed for the purpose of studying the fundamentals of the process and possible improvements therein.

The operation of a gas producer when burning coke at high temperature, at high capacity and eliminating ash and clinker by slagging.

The smokeless combustion of low-grade fuel in boilers when using mechanical stokers.

Operation of the long combustion chamber, designed to make a comprehensive investigation of the processes of combustion in boiler furnaces and the conditions requisite for complete combustion with coals of varying volatile matter, with various rates of firing and heating of coal with variations in the amount of air supply and in the rate of mixing of air with the volatile combustible.

Building No. 17.—Demonstration of the relative safety of single gauze and double gauze bonnetted safety lamps when subjected to a current of gas and air containing eight per cent. of methane and ethane at a known velocity.

The training in a noxious atmosphere of men wearinfi different types of rescue apparatus.

Exhibition of apparatus for the physical testing of explosives, including ballistic pendulum, pressure gauge, calorimeter, flame test apparatus, rate of detonation apparatus, large and small impact machines, cone and pendulum friction devices, and Trauzl and small lead blocks.

Building No. 32.—Demonstration of lignite and coal briquetting plant, making briquets from California lignite.

Gas and Dust Gallery No. 2.—Test of an electr mine motor surrounded by an explosive mixture gas and air, and provided with explosive proof pr tection device.

Event II.—9.30 a.m.

Gas and Dust Gallery No. 1.—To determine the e fect of a charge of a permissible explosive, equivale in disruptive force to one-half pound of forty per cen nitroglycerine dynamite, tamped with one pound dry fire clay, when fired into a mixture of gas an air containing seven per cent. of methane and ethan

Note.—At Forbes Field, October 31, at 10.30 a.m Events II. and III. will be repeated in the presenc of coal dust instead of mine gas.

Event III.—10 a.m.

Gas and Dust Gallery No. 1.—To determine the e fect of a charge of FFF black blasting powder, equ valent in disruptive force to one-half pound of 40 pe cent. nitroglycerine dynamite, tamped with tw pounds of dry fire clay, when fired into a mixture gas and air containing seven per cent. of methane an ethane.

Event IV—10.30 a.m.

Near Gas and Dust Gallery No. 1.—Illustrating th ignition of coal dust by means of the laboratory coa dust ignition apparatus devised and used by th Bureau of Mines.

Event V.—11 a.m.

Gas and Dust Gallery No. 2.—Illustrating the effec of removing the explosion proof protective device from an electric mine motor operating in an explosiv mixture of gas and air.

Event VI.—11.10 to 12 m.

Building No. 21.—Chemical and physical laborato ies: Inspection of fuel, oil, explosives, gas, and othe laboratories.

United States Bureau of Mines Explosion at Exper mental Mine.

Near Bruceton, Pa., Oct. 30.

2 p.m. Leave Pittsburg on special train over th Wheeling Branch of the Baltimore & Ohio Railroad

2.30 p.m. Arrive at Experimental Mine.

2.30 to 3.30 p.m. Inspection of Exeerimental Mine.

3.45 p.m. Explosion in Experimental Mine.

4 to 4.45 p.m. Inspection after explosion.

5 p.m. Return to Pittsburg by special train.

Programme of National Mine Safety Demonstration

Tuesday, October 31, 1911.

Forbes Field, Pittsburg, Pa.

Field Officers.—Manager of Field Events, J. W Paul; Field Marshal, Francis Feehan; Chief Usher J. K. Clement.

Event I.—9 to 10.30 a.m.

Demonstration of first aid to the injured by team of men representing mining companies from all sec tions of the United States of America.

Problems I, II, III, IV, V. (These problems to b published October 1).

Companies represented in demonstration of first ai to the injured and personnel of teams. (This to b filled in after entries have closed on September 30).

Rules.

1. The officers shall be as follows: A manager of ents, a secretary, and assistants, a field marshall id assistants, and a chief usher and assistants.

2. Each team may be identified by the number worn y the captain, the same corresponding to the num- er on the printed list of teams on the final pro- ramme.

3. Each team shall perform according to the num- ers assigned; all holding odd numbers performing gether; subsequently, those holding even numbers, gether.

4. All patients must be placed on stretcher after ach treatment. All artificial respiration must be iven for one minute.

5. No practicing shall be permitted on the day of emonstrations, nor shall the patient assist in any reatment.

6. As soon as an event has been completed, the eam shall stand at position and the captain shall aise his hand.

7. The number of each event will be displayed, as erformed upon the bulletin board.

8. The beginning and closing of each event will be lesignated by the sounding of a gong. Two signals vill be given for removal of bandages.

EVENT II.—10.30 to 11.30 a.m.

Part I.—A permissible explosive, equal in disruptive force to one-half pound of 40 per cent. nitroglycerine dynamite, tamped with one pound of dry fire clay, will be fired into the gallery.

No explosion of the coal dust is expected.

The Forbes Field Dust Gallery.

This gallery is cylindrical, 133 feet long, and an internal diameter of six feet four inches, and represents an underground tunnel or part of a coal mine. The explosive is fired into the end of the gallery. Within the gallery are 133 pounds of fine coal dust from the Pittsburg seam, distributed uniformly throughout, and 20 pounds on a wooden bench 20 feet long near the mouth of the cannon, making a total of 153 pounds of coal dust.

Part II.—Demonstration of the use of birds in exploring mines after explosions or mine fires, at which carbon monoxide causes a large percentage of the fatalities. A few birds, which are much more sensitive to the effect of poisonous gas than men, can be taken into a mine with a rescue party, and as soon as they show signs of distress, the party can retreat to safety. In the demonstrations a man will enter a glass box, the atmosphere of which contains 0.25 of 1 per cent. of carbon monoxide gas, and remain there for some time after the birds have collapsed.

Part III.—A charge of FFF black blasting powder, equal in disruptive force to one-half pound of 40 per cent. nitroglycerine, tamped with dry fire clay, will be fired into the gallery containing 153 pounds bituminous coal dust, being the same dust as that used in Event II, Part I.

An explosion of coal dust is anticipated.

Part IV.—Foremen miners of the Bureau of Mines, equipped with various types of artificial breathing apparatus, will enter the gallery immediately after the coal dust explosion and recover supposed victims of mine explosion. First aid miners of the Bureau of Mines will resuscitate those overcome by noxious gases, using artificial respiration and oxygen respirating apparatus. They will administer first aid to the injured, using in this demonstration only the pocket first aid packet and those things which might be near after an explosion in a mine.

EVENT III.—11.30 to 12 Noon.

Introduction of President Taft by Joseph A. Holmes, Director, United States Bureau of Mines.

Presentation of medals, by William H. Taft, President of the United States.

Address, John K. Tener, Governor of the Commonwealth of Pennsylvania.

Address, Walter L. Fisher, Secretary of the Interior.

Address, Miss Mabel Boardman, American National Red Cross Society.

EVENT IV.

Parade of 19,927 miners, each of whom in his person represents one of the 19,927 men killed in the coal mines of the United States in the last twenty years.

Miners to march in review before the President's stand, and then to special cars on Forbes Street, which will carry them to the river front, where they will witness the marine parade commemorative of the Centenary of the Opening of Steam Navigation on the Ohio River.

NATIONAL MINE SAFETY DEMONSTRATION.

Entrance Rules.

The following rules, with suggestions, are sent mine operators who expect to enter first aid teams in the National Mine Safety Demonstration.

Rule 1.—The National Mine Safety Demonstration will be a non-competitive exhibition of skill in first aid to the injured in mines.

Rule 2.—Not more than one team of five men to represent any one coal mine, or the U. S. Bureau of Mines, or state mine departments, except that coal mining companies operating more than one mine may enter additional teams representative of groups of miners, helpers, trapper boys, or other mine workers.

Rule 3.—All persons entering to submit certificates showing that they are, or have been, bona fide mine workers.

[Suggestion—Submit a brief statement by one of the state mine inspectors to the effect that Messrs. John Doe, Richard Roe, etc., have worked in and around coal mines (give minimum length of time). (Signed and dated:— Inspector).]

Rule 4.—All entries to close one month prior to date finally selected for the meet (viz., Sept. 30, midnight).

[Suggestion.—The entries, like the certificates, need not follow any particular form, being merely a letter stating that you enter the following men, giving the full name of all entrants with the company name and official in charge.

Positively no entries will be accepted after October 1, since names are to appear on souvenir programme, which will go to press that day.]

Rule 5.—Coal companies entering teams to be invited to present, not later than one month in advance of the meet, viz., Sept. 30th, a list of five events as their choice, these to be submitted to the managers, who will select five for adoption from the various events suggested, each entering team to exhibit in these events suggested by them and such others of the five as they may elect.

[Suggestion.—The five events you prefer will, with others, be submitted to the committee to the committee of managers, who will select for the public exhibit frrom all those sugestions, the five which have the majority of recommendations. No suggestions will be received after October 1, on which date the five events selected will go to press. You will be notified prompt-

ly of the events decided upon so that your team may practice them. It is essential that you do this in order to assure that your team can perform within the time limit fixed for each event. The programme must President Taft is limited.]
be run off with snap and speed, since the time of

Rule 10.—Souvenir badges of the American Red Cross, souvenir buttons of the U. S. Bureau of Mines, and souvenir programmes will be presented to individual entrants; a souvenir first air box to each team entering; a souvenir pennant with the name of the company sending entrant, and to be used on the field as a marker, to be presented to the company represented.

Rule 13.—Each team will select its own subject in addition to the five operating members thereof, or will have a miner present, selected for them.

Rule 14.—In this exhibition, the correct use of the roller bandage of the triangular bandage will be given the same credit. In dressing wounds, the first aid packet only will be used. There will be no restrictions as to the make of the first and packet. Teams are to bring their own material, consisting of splints, cotton, bandages, first aid packets, picric acid gauze torniquots, stretchers, and at least two woolen blankets.

THE BENONI CONSOLIDATED PLANT.

A Modern Gold Mill.

Our Porcupine readers will be much interested in the following description, culled from the South African Mining Journal, of a large new plant that is soon to be put in commission. It represents the last word in mill equipment:

At the present time the mine is only being developed by the east and central shafts, and the ore hoisted through these two shafts will be carried by bottom discharge hopper trucks, and dumped direct into the main ore bin at the reduction works, which has a capacity of 1,000 tons. From this bin the ore will be fed on to conveyer belts and carried direct to the crusher station. The crusher station, which is of steel construction, is laid out for double sorting. The crushers are of the jaw type, 30 in. by 28 in. in size, and are four in number, three serving the intermediate sorting belts and one the coarse sorting belt. They are belt driven from a countershaft operated by a 150 h.p. motor. The fines from the Nos. 1 and 2 fines bins are carried by a belt, which, after passing over a weighing machine, feeds them on to a shuttle belt conveyer erected above the mill bins. This conveyer distributes the fines to the mill bins, which have a capacity of 2,000 tons. Both the mill bins and building are of steel construction.

The battery consists of 55 stamps of 2,000 pounds weight, operating in open-fronted mortar boxes, which stand on anvil blocks bolted to heavy concrete pile blocks. The king posts, which are of cast steel of special design, are secured to heavy wooden timbers bolted to the concrete pile blocks, whilst the guide beams are also of cast steel and are fitted with cast iron guides for the stamps. The stamps are arranged in batteries of five each, each battery being electrically driven. The tube mill plant consists of four 22 ft. by 5ft. 6 in. tube mills, each operated by a belt drive from an A. E. G. motor. The shaking tables are of the usual type, and are 28 in number—seven for each tube mill. The pulp, after passing over the amalgamating tables, is lifted by two 8 inch pumps to a second series of four Stadler classifiers, the overflow from wh passes to the cyanide works, whilst the underflow returned to the tube mill circuit.

The overflow from the Stadler classifiers, just m tioned, passes to primary and secondary Stadler cla fiers, the final underflow from which goes to a 21 diameter Caldecott filter table, whilst the final ov flow runs to three 21 ft. diameter Arbuckle dewat ing cones. The dewatered products from these t sets of apparatus pass together to the first set of fo mixing agitators, 8 ft. diameter by 22 ft. high, whe they are mixed with the required quantity of stro cyanide solution, and then pass to a series of Wa Arbuckle air agitators, in which the gold dissolvi process is carried out. These agitators are so a ranged that they can be used in series or in parall as desired, it being possible to short-circuit any o tank or section of tanks as required. The combin sand and slime, together with the gold in solution, then lifted by two 5 in. pumps to a Stadler classifie the overflow from which goes to the first set of thr 21 ft. diameter Arbuckle desolutionizing cones, the u derflow from which cones joins the underflow fro the Stadler classifier and passes to the second set four mixing agitators 8 ft. in diameter by 22 ft. hig where they are mixed with a weak wash cyanide sol tion. The sludge from these agitators passes to a se ond series of primary and secondary Stadler class fiers, the final underflow from which is treated on second 21 ft. diameter Caldecott filter table.

The extractor house is fitted with eight 12-co partment steel extractor boxes and with the necessa motor-driven solution pumps. The solution, aft passing through the boxes, gravitates to the stro solution tanks, from which it is lifted by two 5 i pumps to the first set of mixing agitators. The clea up room is fitted with the usual appliances, and under the same roof as are the shaking amalgamatin tables in order to simplify supervision. The whol plant has been laid out with a view to simplify joi administration with the plant to be ultimately erecte by the Apex Mines (gold section), and at the sam time in such a way as to permit any unit of eithe plant to be enlarged to any extent that future deve opments may render necessary.

CANADIAN MINING INSTITUTE — WESTERN BRANCH.

Eleventh General Meeting.

The eleventh general meeting of the Western Branc of the Canadian Mining Institute was opened at Ne Denver, Slocan Lake, B.C., on Wednesday evening September 13, Mr. Robert Hedley, of Vancouver. B.C chairman of the Branch, presided, and among thos present were the following: Wm. Fleet Robertso provincial mineralogist, and E. Jacobs, branch secre tary, Victoria; S. S. Fowler and A. H. Gracey, Nelson Thos. Kiddie, Vancouver; M. E. Purcell, superintend ent of the Consolidated Mining and Smelting Co.' Centre Star group of mine, Rossland; A. J. Becker Lucky Jim mine, Slocan; John Vallance, superintend ent Standard mine, Slocan, and the following visitin members: C. E. LeRoy, of the Geological Survey, an Dr. A. W. G. Wilson, Cosmo T. Cartwright, and L Heber Cole, all of the Mines Branch, Canada Depart ment of Mines, Ottawa. Other visitors included M. S Davys and H. M. Ridge, London, England; W. An derson, C.E., Vancouver; H, Nation, Bureau o Mines, Victoria; A. H. Tuttle, Wilcox mine, Ymir

C. V. White, superintendent Slocan Star mine; Sandon; W. A. Cameron, Richmond-Eureka mine, Sandon; Thomas Avison, Alamo mine; J. C. Moen, Black Prince mine; S. A. Griffith, Eastmont mine; Ed. Shannon, Enterprise mine; T. J. Lloyd, Van Roi mine; Alex. Smith, Surprise mine; Julius Wolff, Mollie Hughes mine; Geo. H. Ayland, general manager Standard Silver-Lead Mining Co., Silverton; Capt. Harry Johns, Wellington group mines, Boundary; J. V. Richards, and O. Jeldness, Spokane, Wash.; John Wagener, Butte; Mont. A. Lakes, Jr., Denver, Colorado; Wm. Hunter, M.P.P., Silverton; Wm. Thomlinson, G. B. Webster, A. E. Ritchie, Colin J. Campbell, W. P. White, formerly superintendent of the St. Eugene mine, East Kootenay, and about 30 others.

On behalf of the New Denver Town Improvement Society, Mr. J. C. Harris read an address of welcome to the visitors, and he was followed by Mr. W. Hunter, M.P.P., who also heartily welcomed the visitors. The chairman replied briefly in acknowledgement, and then delivered an address.

Chairman's Address.

The chairman, Mr. Hedley, after having thanked the Town Improvement Society and Messrs. Harris and Hunter on behalf of the residents of New Denver and district for their cordial welcome, first mentioned the natural beauty of the district, which had always attracted him since his first visit to it in 1898; and then referred to two items of general interest to the public which had been published the previous day in the Nelson Daily News. One of these was an account of a new find of an apparently large body of carbonate of lead on Deen Creek, Nelson mining division, which had been sufficiently opened by its owners to draw to it the attention of the Consolidated Mining and Smelting Co., of Canada, Ltd. The other was the information made public to the effect that A. Gordon French had succeeded at his small plant in Nelson in handling the complex zinc ores of the country. Mr. French first roasts the ore, then dissolves the zinc by aid of a chemical reagent, recovers the zinc in metallic form by electrolysis, and smelts the residue for lead and silver. He (the speaker) wished Mr. French God-speed, and hoped he would make a commercial success of his zinc reduction process, which would be of inestimable benefit to the country.

He next said: "The Canadian Mining Institute enjoys a high standing among the technical societies of the world, and our Transactions are recognized as embodying material that is the result of the experience of men of brains and capacity for doing things. Among our members are men of attainment in all branches of the mining and metallurgical industries and research, and they do not hesitate to give their best efforts toward the advancement of the Institute. Our facilities in Canada are second to none. In addition to the well equipped and constantly improving testing plants of the Dominion Government, and of McGill and Kingston, we have metallurgical plants at Sudbury, Ontario; at Trail, and Boundary, B.C., and elsewhere, which stand in the front rank for efficiency. I was much impressed the other day to hear Mr. Hugh F. Marriott, consulting engineer of the Central Mining and Investment Company of London, say that he had arranged with McGill University, Montreal, to complete certain research work in its metallurgical department.

"At the last meeting of this branch we were asked to approach the Provincial Department of Mines, asking that it take further steps toward assisting in opening our vast unknown fields, by sending capable engineers to observe the geological structure to the end that the Government might advise prospectors of favourable conditions. This did not seem to arouse much interest, and was disposed of without discussion. It seems to me there is a much better field in which the Institute might endeavour to improve the conditions of the mining industry of the province, and that is the field of company promoting for mining enterprises. In this we could well ask the co-operation of the Provincial Government.

"Why is it that the general public — the cautious public — shies at a mining proposition? Why has mining enterprise fallen into disrepute? You and I know it is not for lack of opportunity to select judiciously and operate a mining property that will make good.

"About 18 months ago, Mr. Thomas Kiddie told the Vancouver Canadian Club, when addressing a large meeting of that organization, what a very small proportion of the money subscribed for mining was used for actual mining operations. The long-suffering public has been asked lately to subscribe to many schemes that from their inception were impossible of success, and impossible from either crass ignorance or deliberate and premeditated dishonesty. Often both these combine to fleece our investing public. Now, can you in some measure protect the public. They must, of course, take some chances.

"Mining enterprises that start as prospects cannot be sure of success, but they can be protected against that class of investment that is from the start absolutely sure of failure. Most of us can recall one instance, perhaps many instances, of company promotion that was predestined to failure from one or more of the following reasons: (1) The prospect gave but little reason to hope that it ever could yield commercial ore. (2) The proposed distribution of the capital was such that there was no chance for the sufficient development of the property. (3) The management of the company's affairs was placed in grossly incompetent hands. (4) Often it has been the case with a property of some merit, that large blocks of promoters' shares were issued and a small block sold to raise working capital. This might have been sold at 25 cents a share with the expectation that when needed further capital could be raised by selling another block at a higher figure. Before that became necessary, however, the promoters' shares might have been offered for what they would bring, and the market consequently so demoralized that treasury sales became unsalcable.

"It should, I think, be made a misdemeanour to (1) promote a company to operate a mine that has little if any reason to hope for commercial ore; (2) to so distribute the capitalization that the treasury is inadequately supplied; (3) to place the management in grossly incompetent hands; (4) to sell promoters' shares before the property has been developed beyond the prospect stage.

"Surely this Institute can approach the Provincial Government with a view to persuading it to so legislate so that it shall be required that all prospectuses shall be submitted to an advisory committee to detect faults, if any, that will surely lead to failure of the enterprise. It may not be necessary to ask for a staff of Government engineers who will investigate and pass on the merits of the proposition, if it be required that the opinion of a reliable mining engineer be obtained before proceeding to promotion. The ideal way, of

course, is to develop prospects to a certain point where there is a fair chance of making good, by a syndicate or a development company. Mr. Marriott, when commenting on the fact that there are so few mining properties sufficiently developed to attract his company, said: 'What you need here is a few good development companies.' ''

After a few further observations by Mr. Hedley, a discussion ensued, in which Mr. H. M. Ridge (who gave the meeting information relative to some of the disadvantages that had followed the passing in Great Britain of laws intended for the protection of the public from abuses in connection with company promotion), and Messrs. Kiddie, W. F. Robertson, E. Jacobs, and others.

Reading of Papers.

Papers were read, as under:

1. ''Early Slocan Days,'' by Prof. J. C. Gwillim, School of Mining, Kingston, Ontario.

2. ''Notes on Minerals Found in Slocan District,'' by Wm. Thomlinson, New Denver, B.C.

3. ''Notes on Geology and Ore Deposits of the Slocan,'' by O. E. LeRoy, of the Geological Survey of Canada.

4. ''Costs and Cost Conditions at the Blue Bell Mine, Kootenay Lake,'' by S. S. Fowler, Riondel, B.C.

5. ''The Lucky Jim Zinc Mine, Slocan, B.C.,'' by A. J. Becker, superintendent.

There was also some discussion on the present position of the zinc ore reduction question in British Columbia, in connection with which reference was made to W. R. Ingalls' paper on ''The Problem of Mixed Sulphide Ores.''

ROTARY CONVERTERS FOR MINING SERVICE.

Rotary converters are being used in many coal and metal mines. Direct current is necessary for the operation of mining locomotives because alternating current motors cannot satisfy the speed and space requirements. Alternating current is used for the transmission of the energy from the steam or hydro-electric generating stations to the mines, and the rotary converter is the logical machine for efficiently converting the alternating to direct current at the point where the energy is to be used.

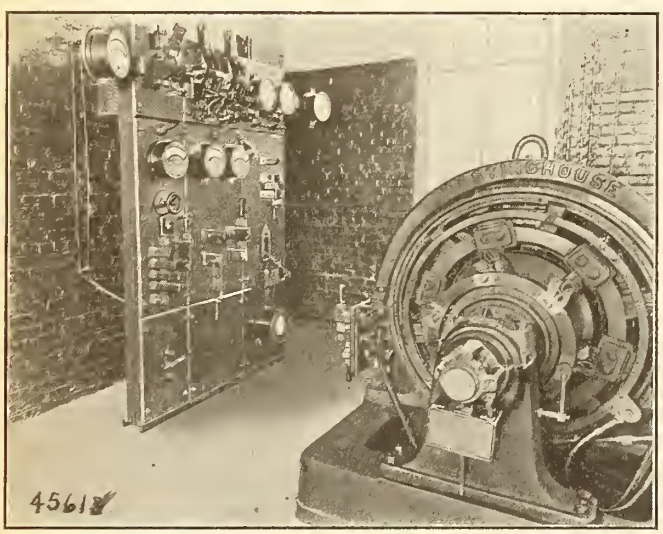

Fig. 1

Several public service companies in both Pennsylvania and in Colorado are making a specialty of supplying mines with alternating current energy and are developing excellent mining loads. The larger mining companies find it economical to establish steam or hydraulic generating stations at points where energy can be generated cheaply and to transmit it as high tension alternating current to the mine or group of mines where it is utilized. Whether alternating energy is generated by a public service company or by the mining company, experience shows the rotary converter to be an efficient, reliable machine for converting the alternating to direct current. A nominal voltage of either 275 or 600 is adopted for the direct current distribution systems within the mines.

A good example of a mining plant rotary converter installation is shown in fig. 1, which is a view of the substation at Mine No. 22 of the Consolidated Coal Company of Pennsylvania. This station received energy as alternating current at 2,300 volts, three-phase, 60 cycles. The pressure is stepped to 158 volts for the alternating side of the Westinghouse 150 k.w. rotary, and is delivered therefrom as direct current at 275 volts. A standard Westinghouse black marine finished switchboard, carrying the usual switch gear and instruments, controls the incoming alternating current line, the rotary converter, and the outgoing direct current feeders, which radiate to different parts of the property.

In large mines it is sometimes expedient to locate rotary converter substations underground near the centre of the area that they serve. Such an underground substation of the Consolidated Coal Company is shown in fig. 2. The room forming the station is lined with brick, which is waterproofed on the outside, and the roof is arched so that it will drain and that dripping water cannot damage the apparatus. The incoming lines to this station are alternating current, 2,300 volts, three-phase, 60 cycles, and the 150 k.w. rotary converter delivers direct current at 275 volts. The transformers stepping down from the alternating transmission voltage of 2,300 to the alternating rotary voltage of 158 are located in the substation. (See fig. 2). A pipe frame work arranged over the high tension transformers supports the high tension bus-bars. A two-panel black marine finished switchboard carries the equipment for metering and

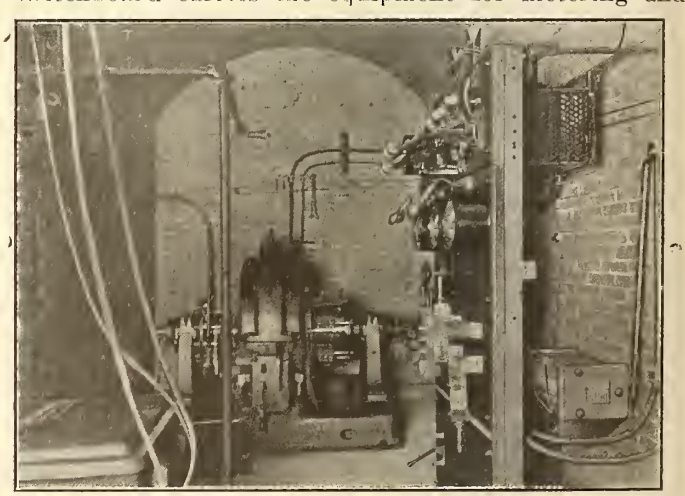

Fig. 2

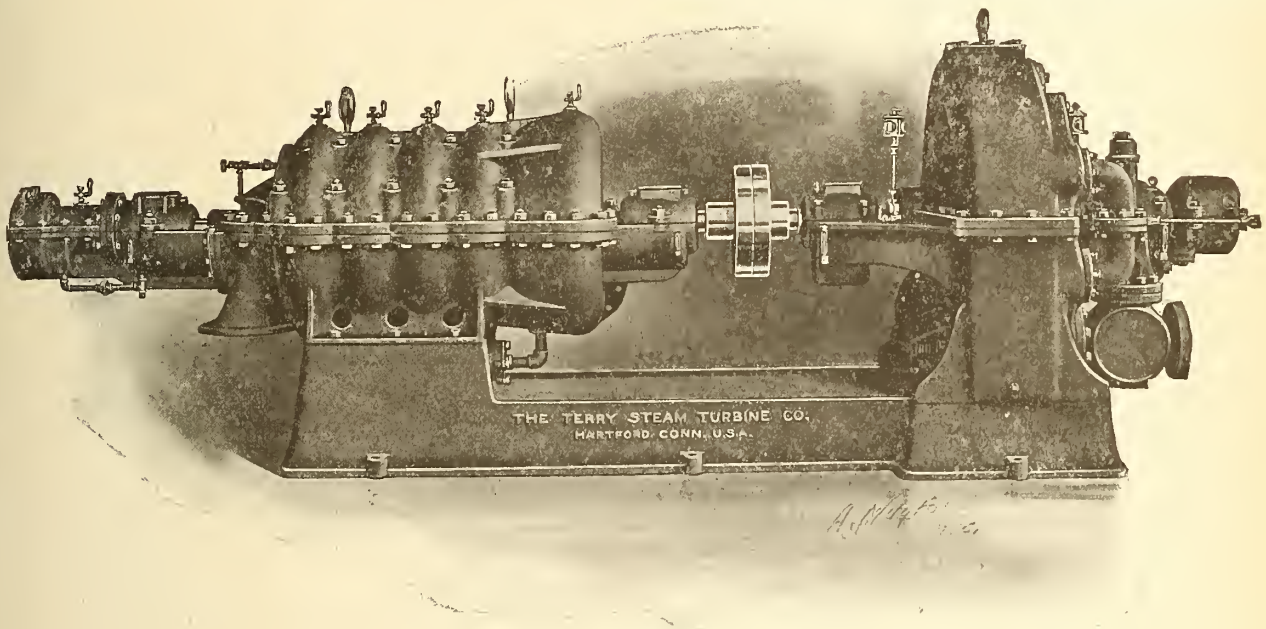
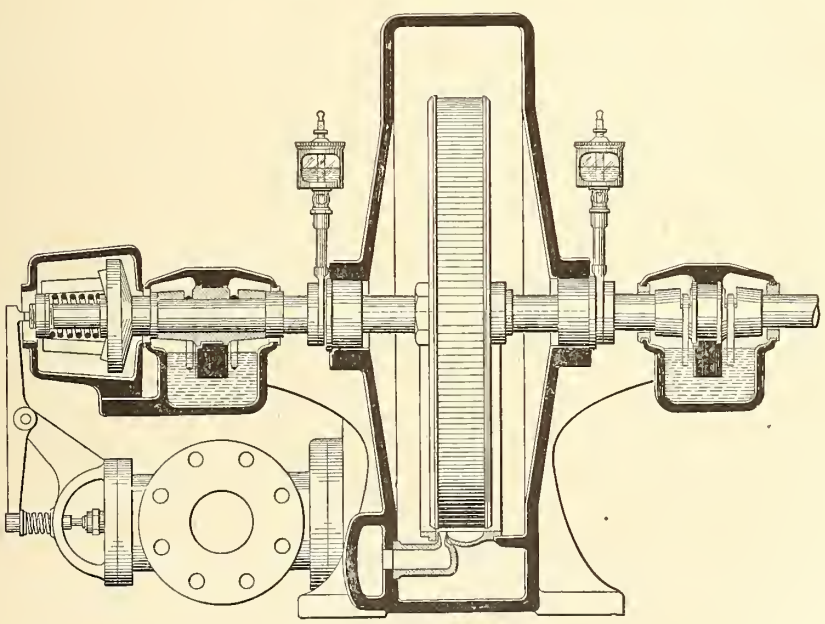
controlling the incoming and outgoing lines, the transformers, and the rotaries.

Armored lead-covered cables are generally used to convey the high voltage energy to an underground substation in a mine. The cable is usually carried down a bore-hole rather than through the workings, so that the chance of injury from falling rock and from interference will be minimized.

Turbine Driven Centrifugal Mining Pumps.

For keeping mines free from water and for creating hydraulic power for placer mining, the turbine-driven centifugal pump in its present development is peculiarly applicable. The very small dimensions of such sets would commend their use where space conditions are important without very deep inquiry into their other virtues. Turbine pumps can be started up at any time from a cold condition and once started operate for an indefinite time until stopped by the simple closing of the throttle valve. To those unfamiliar with the modern turbine and centrifugal pump the power and speed of these machines is almost incredible.





For example, the larger illustration shows a Jeanesville 5-stage centrifugal pump driven direct-connected by a single-stage Terry steam turbine. These units are about 48 inches in height and not over 10 ft. in length, yet have a capacity of 1,000 gallons of water per minute against an average discharge pressure of 270 lbs. The small size and simple construction is in striking contrast to the great weight of a reciprocating pump for the same service.

As a means of propulsion for centrifugals no machine has yet been devised which fills the bill as satisfactorily as the small steam turbine. Because of its superior range of speed it is possible to get a unit of much smaller diameter than would be necessary in a larger pump driven by a reciprocating engine. The accompanying cuts show its extreme simplicity; there is but a single row of buckets on the rotor. This single-stage feature reduces complications, but in order that the speed shall be normal the steam in the course of its expansion is made to traverse the buckets several times, each time being redirected into the wheel through return passages in the casing. The wheel thus receives energy in successive stages and therefore the peripheral speeds are much lower than would be the case if the steam impinged on the wheel but once.

INTERNATIONAL COAL AND COKE CO., LTD.

The colliery of the International Coal and Coke Co., Limited, is situated at Coleman, southwestern Alberta. The head office of the company is in Spokane, Washington, U.S.A.

The annual meeting of the company is held on the fourth Thursday in March in each year. The printed "Seventh Annual Report of the Directors" to the shareholders in the company, however, was not circulated until the latter half of August, ultimo. It should be noted, therefore, that the period covered by the appended report and balance sheet was the calendar year 1910, so that the information given below relates to an earlier time than that during which the strike of coal miners and other employees of the various coal-mining organizations comprising the Western Coal Operators' Association was in progress, which strike took effect as from March 31, 1911, since which date there has not been any production of coal or coke at the company's colliery at Coleman, though the payment of the quarterly dividend has been continued, the same having been made out of accumulated funds.

The report and balance sheet follow:

Directors' Report—

"The net profits for the year, after paying all operating expenses at head office and mine, amount to $300,097.02, which sum has been derived from the various departments of the company's business, including the sale of coal and coke, receipts on account of lots sold from the company's townsite, and returns from rentals, water and electric light.

"On the 1st of February, May, August, and November, a dividend of 1½ per cent. was paid, aggregating $180,000, and, as will be seen by reference to the accompanying balance sheet, the handsome sum of $120,097.02 was carried to surplus account for the year.

"The total amount of the payroll for 1910 was $567,974.99; average number of men employed, 524; days worked, 280. During the year there were additions made to coal lands, plant and equipment (expenditure under this head being $71,958.10) all of which were deemed necessary in the company's best interest and approved by the board."

The balance sheet as at December 31, 1910, is as under:

Liabilities.

Capital — authorized and issued		$3,000,000.00
Dominion Government — Balance of royalty on coal mined between 1903 and 1909, payable at $3,000 per month		58,019.97
Accounts payable — Sundry	$ 19,362.96	
December payroll, payable Jan. 14, 1911	49,347.81	
Unclaimed dividends	882.36	
		69,593.13
Reserve for Contingencies		39,448.16
Surplus—		
As shown December 31, 1909	$634,595.93	
Less items chargeable against 1908	5,018.19	
	$629,577.74	
Net profits earned during 1910	$300,097.02	
Less dividends paid during 1910	180,000.00	
	120,097.02	
		749,674.76
		$3,916,736.02

Assets.

Coal lands	$3,103,214.31
Plant, dwellings, horses, etc.	606,295.41
Warehouse stock	45,098.08
Accounts receivable	119,447.53
Stocks of coal and coke	3,572.32
Unexpired insurance	3,679.53
Timber rights	4,304.82
Cash on hand and in bank	31,124.32
	$3,916,736.02

WESTERN BRANCH C. M. I. MEETINGO

The Lead Bounty Situation.

The following figures obtained by E. Jacobs for submission to the recent meeting of the Western Branch of the C. M. I., at New Denver, B.C., show the balance unexpended as at July 1, 1911, of the amount of $2,500,000 originally voted for the payment of a bounty on lead mined in Canada:

Total expenditure (under old Act) for period ended June 30, 1908		$ 700,390.04
Expenditure during fiscal year ended March 31, 1909		274,447.50
Expenditure during fiscal year ended March 31, 1910		343,099.08
Expenditure during fiscal year ended March 31, 1911		249,370.38
Expenditure during three months ended June 30, 1911		49,713.32
Total paid as bounty on lead		$1,617,020.32
Add amount appropriated for zinc ore reduction experiments, etc.		50,000.00
		$1,667,020.32
Balance available as at July 1, 1911..		832,979.68
Total amount voted		$2,500,000.00

On Thursday morning, September 14, about 20 members and visitors were conveyed in gasoline launches from New Denver down Slocan Lake to Silverton, and driven thence to the Standard silver-lead-zinc mine (Note—This mine was described in the Canadian Mining Journal of Dec. 15, 1910). The very large body of clean galena exposed on No. 5 level of the mine excited much interest among the visitors, the greater number of whom also went into the intermediate and No. 4 levels, and afterwards into No. 6. The last is in about 2,000 feet from the portal and is just entering the downward extension of the big oreshoot opened in No. 5, below which it is 190 feet, vertical depth.

After having been hospitably entertained at luncheon by Mr. Geo. H. Aylard, general manager of the Standard Silver-lead Mining Company, the visitors

next went to the Wakefield concentrating mill, operated by the Silverton Mines, Ltd., owning the Hewitt-Lorna Doone mines, distant about a mile up the mountain. Then the new concentrating mill of the Van-Roi Mining Company, Ltd., was inspected, the company's resident superintendent, Mr. Douglas Lay, showing the visitors through the works. Here refreshments were liberally served, and then the return trip was made.

In the evening, after dinner, a smoking concert, given by the citizens of New Denver in honour of the visitors, was held, and this was numerously attended and a very enjoyable evening spent.

Next day the visitors dispersed in various directions, and the New Denver meeting, which had proved one of the most enjoyable and successful the Western Branch has held, was a thing of the past.

SPECIAL CORRESPONDENCE

ONTARIO.

Cobalt and Gowganda.

Probably the best strike yet made on the Nova Scotia was that reported a few days ago, when No. 14 vein was encountered 50 feet below the first level. The vein shows three inches of calcite, smaltite, and silver that runs 5,000 ounces to the ton. At the 100-foot level on this vein high values were obtained, the ore assaying 13,000 ounces.

The report of the returns to the Ontario Department of Mines, recently issued, shows that the silver production of the Province, of which 95 per cent. comes from Cobalt, was 15,231,969 ounces in the first six months of 1911. This amount is valued at $7,644,200. The increase in value over the silver produced in the first half of 1910 is over $1,300,000. The shipments consisted of 7,733 tons of ore and 4,380 tons of concentrates, while in addition, 1,302,699 ounces of bullion were shipped. Although shipments this year have been much below those of 1910 in tonnage, the higher value of the ore shipped, and the increased amount of concentrates, has brought the total values up to a sum exceeding that of last year's shipments. In the six months Gowganda shipped 110 tons of ore and 2 tons of concentrates, while South Lorrain shipped 216 tons of ore, the whole containing 430,540 ounces of silver.

The quarterly report of the Beaver Consolidated Mines, Limited, shows that there is cash on hand of $59,960.45. During the three months ending August 31, drifting, cross-cutting, sinking, and raising to the extent of 1,102 feet was accomplished. Eight cars of ore were shipped by the company, two of them of high grade.

There is a possibility that the Alexandra mine will resume operations. Mr. E. W. Beidler, of Buffalo, is at present in the camp looking over the property, where the main shaft was sunk to 200 feet before work ceased.

Shipments of ore for the week ending September 8th were noteworthy because of the falling off from the average which had been maintained for several weeks previous, only 10 cars being despatched from the camp by eight mines, totalling 618,120 pounds. Several bullion shipments were made in that week. Two consignments of bars were made by the Nipissing, one of 47 bars, worth $26,366, and one of 43 bars, valued dat $23,615. The O'Brien shipped 18 bars worth $8,773, the Drummond 2 bars worth $681, the Wettlaufer 1 bar of 22 pounds, valued at $160, and the Nova Scotia shipped 22 bars, valued at $17,500.

For the week ending September 15th the ore shipments were the second highest of any week this year, over 600 tons leaving the camp. There were 663.67 tons in the 20 cars shipped, McKinley-Darragh leading with 4 cars of high grade. Following are the figures for the week:—

	Tons.
McKinley-Darragh, 4h	134.66
La Rose, 21	74.14
Coniagas, 2h	61.57
Drummond, 21	60.00
City of Cobalt, 1h	53.00
Trethewey, 2h	50.40
Cobalt Townsite, 1h	50.26
O'Brien, 1h	32.00
Chambers-Ferland, 1h	32.00
Temiskaming, 1h	31.11
Cobalt Lake, 1L	31.00
Kerr Lake, 1h	30.31
Buffalo, 1h	23.20

Bullion shipments were made during the week by the Nipissing, which sent out 36 bars, valued at $20,550; and by the Buffalo, which sent out 8 bars, worth $4,844.27.

Shipments for the month of August were the heaviest of any month this year, exceeding those of any other month by over 500 tons and those of July by almost 1,000 tons. Eighteen mines shipped a total of 86 cars during the month, 55 of these being of high grade, the shipments amounting to 5,426,934 pounds.

West Shining Tree, about 40 miles northwest of Gowganda, is the centre of the latest rush of gold seekers. It is reached either by rail and canoe from Sudbury, or by trail from Elk Lake and Gowganda. The Gosselin claims, whose rich deposits started the stampede, are located in Churchill township. They were sold a few days ago for $300,000, it is reported. In addition to Churchill, the townships of McMurchy, Asquith, and Fawcette are practically all staked up, and many prospectors are going in daily. It is said that representatives of the big Dome interests are in the district looking for promising claims. Inside of a week or so the C. N. R. will have its extension within about 15 miles of the district.

On the Moosehorn property, in James township, a rich mineral deposit has been uncovered in the course of trenching operations. Samples taken of the vein have been sent away to be assayed, and as yet the actual value of the find is not known, but it is considered rich by the official of the company.

Porcupine and Swastika.

Cody Township is coming to the fore with the reported discovery of free gold on a property being worked under the direction of A. J. Bouzan, son of the manager of the La Palme property. The belt of schist in which the quartz is found is 20 feet wide. Assays ran from $4 to $30.40 per ton.

While stripping and trenching at the Rea property, what is thought to be a continuation of the main vein was struck a few days since. The vein is 60 feet in width and pans gold freely. Underground work is progressing rapidly.

Although little is heard of the district near Matheson, yet considerable development work is being carried on in Munro Township. Several companies have shafts down 100 feet or more, and on the Porcupine Townsite Mining Company's pro-

perty a 4-foot quartz vein has been uncovered, from which samples assayed $20 to the ton.

The end of the present month will see the new plant at the Swastika mine in running order. The five-stamp mill now in operation will be used as a test mill, but no plans have yet been formulated for the erection of a large mil. Last week connections were made with the raise from the 100-foot level to the surface. This new opening will constitute the main shafe, as the shaft that has been in use for some months past has proven too small. Mr. M. W. Summerhayes, manager of this property for the past three months, has resigned, and Mr. R. B. Lamb, consulting engineer of the mine, is in charge at present.

The new plant for the West Dome is almost completely installed and every effort is being expended in getting camp buildings completed. The boilers for the Dome Extension, two locomotive type portables of 80 horsepower each, have reached the property and are being erected. The new compressor is already in position. At the Dome the greatest activity prevails, hundreds of men being engaged in the construction of the various buildings on the property. Two diamond drills are working and large gangs are engaged in surface work.

Three hundred thousand dollars was the sum paid the Sutherland Brothers, of Toronto, for their two claims in Bristol Township, staked during the early days of the rush in June. Development work on the Thompson, Yates, and Jowse Woods claims in that township continues with excellent r sults.

What is considered by many a most important developme in the Porcupine field is the fact that at a depth of betwe 650 and 700 feet free gold was found by a core drill at t Pearl Lake property. The free gold was found in both t quartz and schist stringers. The vein encountered at th depth is thought to be an extension of the Dixon-McInty vein. Two shafts are being worked on the property just no both being over 100 feet down. A 12-drill compressor ar large motor are being installed and as soon as in running c der, more drills will be set at work below.

Eight drills are at present working underground on the M Intyre, and this number will be increased as soon as mo machines can be secured. Developments underground are qui extensive and good ore is being mined in several of the shaft which have reached the 100-foot level.

A general assay of $20.10 has been obtained from the sam ling of No. 3 vein at the Vipond. Cross-cutting showed feet of ore from which the samples were taken, but the sout wall of the vein had not been reached. This vein was fir reached by cross-cutting the day before the big fire, and the 100-foot level it is much wider than when first encountere

GENERAL MINING NEWS.

NOVA SCOTIA.

(Special to the Canadian Mining Journal.)

Halifax, Sept. 20.—Representations are to be made to the Provincial Government by local mining men with a view to organizing a Royal Commission to report upon the gold mines of the province. Although the Government has not yet been approached it is believed that the proposal will not be looked upon unfavourably. It is recognized by all that some steps must be taken in this direction if only to set matters right in the eyes of the public. The strong investor is needed very badly, and he will not come until he knows more about the mines. The Report of a Royal Commission would arouse interest at once. It could be made absolutely clear and authoritative. There is really nothing to be hid.

Just so long as the present policy of inertia prevails, just so long will the gild mines stand idle.

Three Toronto investors have recently been looking round the Province, but no news has been made public.

ONTARIO.

Cobalt.—Two drills have been started to sink the main shaft of the Temiskaming mine to a further depth from the 575-foot level and at the present time the shaft is now down between 590 and 600 feet. It will be continued to a depth of 650 feet, where the eighth mine level will be cut and all the veins drifted upon at this depth, which will be the deepest by over 75 feet ever atempted by a mine in the Cobalt camp.

Porcupine, Sept. 19.—A new mark for depth in the camp was set Saturday, when the drill penetrated 800 feet at the Pearl Lake Gold Mines, cutting through 60 feet, carrying gold in vein matter of schist and quartz. The drill ran down on an angle, and it is believed the Dixon vein, on the McIntyre, to the south, is encountered.

The drill on the "A" vein reached 350 feet yesterday, bringing up free gold in 25 feet of quartz. Consulting Engineer Lamb reports the new mark as showing mineral all th way down. Hretofore the Dome at 700 feet of drilling hel the record for depth.

ALBERTA.

Calgary, Alta., Sept. 17.—The Trades and Labour Congres of Canada concluded its business and adjourned till next yea when the meeting will be held in Guelph. The time of th session was occupied with a consideration of the various re ports of committees, and there was an acrimonious discussio on several topics, chief of which was the future relations o the Congress with the Social and Moral Reform League. Afte a heated discussion in which the western members bitterl opposed the grant of $50 to the League, the motion to mak the grant, and also the give the support of the Congress t the Moral and Sociay Reform League, was carried after a amendment to discontinue affiliation with the League had bee defeated.

Resolution 64 was considered next. This was a motion by Delegate Hooper of, Winnipeg, to incorporate in the platform of the labour movement the principle of the abolition of the wage system. In a rather long speech, for which he was grant ed extra time, Delegate Hooper advocated his resolution from the standpoint of the Socialist party of Canada. "They were all opposed," he said, "to capital," which he dedfined as the "right to exploit labour."

Another resolution advocating the incorporation ini their platform of the principles of collective ownership and the democratic control of land and capital, was spoken to by se eral members, but the committee's report recommending non concurrence was also endorsed by the assembly.

Section 13 of the officers' report, which was held over for discussion, was proceeded with. This section had reference to the condition of the miners in the present strike in the Crow's Nest Pass and at the invitation of the convention the

rnie delegate detailed the history of the strike and ex-ined why the miners had refused to accept the Gordon re-t. The main reason for their rejection of it lay in the fact t that it recommended an increase to the day wage worker ich had to be paid by the miner who was paid on piece work, d who had to pay the day wage man who was his helper. He d that when they refused to consider or recognize the opera-n of the Lemieux Act, the Minister of Labour had wired em a royal commission would be sent down to investigate d make a report. The miners did not want a royal com-ssion because the appointments to such a body were made litically, and their grievance was not a political one, but is one of wages, and they did not wish to be concerned with liticians.

President Powell, of District 18 of the United Mine Work-s, made a short speech in which he thanked the Congress for e kindness they had shown the mining delegates and for the ant of $300.

BRITISH COLUMBIA.

Hope, B.C., Sept. 19.—During the past week M. C. Williams, M.E., of Hope, B.C., has just concluded a deal which involves a transaction of $100,000. It includes the sale of three groups of claims owned by Andrew Larson & Co., of Vancouver, and Frank Fritz & Co., of Grand Rapids, Mich.

Williams' property has been sold by Mr. Williams to Charles F. Solderling, of Spokane, who will call the new mining camp, 23-Mile camp. It is located within easy reach of Hope.

Coalmont, Sept. 18.—A. S. Williamson, of Williamson & Turner, agents for Coalmont Townsite, arrived in town from Vancouver. He is sepnding a fow days making an inspection of the Columbia Coal & Coke Company's properties here and is more than surprised at the great amount of work which has been done by the company in so short a time.

George L. Fraser, general manager for the coal company, has been absent in Chicago and eastern cities for the past 30 days, where he has been completing the final arrangements for the installation of the company's plant with Messrs. Roberts & Schaffer, of Chicago. While in the east Mr. Fraser has also visited some of the largest coal mines in Pennsylvania.

COMPANY NOTES

CANADA IRON CORPORATION.

The Canada Iron Corporation, of which Mr. T. J. Drummond is president, has just issued its annual report for the year ending May 31st.

Although some of the plants are undergoing construction and are not up to full working capacity, earnings were good.

The profits for the year were $401,885, and the bond interest $175,200, leaving $226,685.

There were minor charges of $16,305, and the year's surplus added to the balance last year of $149,427 made $359,807 of undivided profits carried forward. The showing is thus very satisfactory.

Since the close of the fiscal year the position of the corporation has been further very materially improved through the acquisition of valuable assets which will not show in their statements until the close of the present year.

LE ROI No. 2 AUGUST OUTPUT.

Following is cable sent by the management of Le Roi No. 2 to London head office:—

Le Roi No. 2—"Josie mine report for August—Shipped 2,240 tons of ore and 142 tons of concentrates. The receipts from smelter are $43,579 (£8,985), being payment for 2,314 tons shipped, and $6,364 (£1,312), being payment for 135 tons concentrates shipped. In all $49,943 (£10,297). Estimated costs for corresponding period:—Development, $9,000; ore production, 09,000; milling, $1,250—$19,250 (£3,969). Poorman drift west, 500 ft. level—Advance 20 feet, which averaged 1 oz. 4 dwts. gold and 5 per cent. copper over 9 ins. Rodney drift west from crosscut, 1,200 ft. level—Advance 20 feet, which averaged 11½ dwts. gold and 4¾ per cent. copper over 4 feet. Rodney drift, east from crosscut, 1,200 foot lovel—Addvance 50 feet, which averaged 1 oz. gold and 3¾ per cent. copper over 2½ feet. Rodney raise, 1,200 foot level—Advance 27 feet, of which 27 feet averaged 7 dwts. gold and 5¾ per cent. copper over 2 feet 9 inches."

A EUROPEAN VIEW OF ZINC MARKET.

An interesting review of the position of the zinc market, in which both England and Germany are about equally interested, appeared last month in the "Frankfurter Zeitung" apropos of the recent advances in the price of the metal. During August, according to this account, the price of crude zinc has been raised no less than four times, aggregating a total advance of M3½ per 100 kilos for tho month. The rise was grmly based on the strong and well-sustained demand for zinc by consumers and the reduction of stocks which took place. Production did not keep paco with the extensive consumption. It was free to the zinc foundries this year to increase their output as much as they pleasod; but though the statistics show that an increaso of ontput took place, it was not in proportion with the advance in consumption, and the stocks at the foundries went back to a minimum. They could not supply the quantities for which orders were received in July and August, and the Zinc Foundries Union has recently been repeatedly in the position of only having small quantities to dispose of at the enhanced prices. Reviewing tho course of operations under the Zinc Convention, which was agreed to in 1908, and prolonged by the Zinc Foundries Union to 1916, and by the International Zinc Syndicate to 1914, it will be found that, starting from the low level of £18 to which the price had fallen in 1908, an upward movement has taken place continuously ever since, uninterrupted by any important break. The London price is now at the £27 10s level, while at the beginning of the year it was still £24, as compared with a yearly average of £23 in 1910, £22 6s 8d in 1909, and £20 3s 5½d in 1908. During the years in which all metal prices moved convulsively upwards, namely 1905 and 1906, zinc averaged £25 6s 8d in 1909, and £20 7s 7d in the former year and £27 1s5d in the latter. The advance of late years has been attributed partly to the regulating influonce of the syndicate on prices. Germany's consumption, calculated on the reductions of stocks at the foundries, has increased from 188,100 tons in 1909 to 191,500 tons in 1910, while the export of zinc in zinc and brass goods increased by 100,000 tons to 479,000 tons. In England the consumption for 1910 was 177,800 tons, as com-

pared with 155,500 tons in 1909, and the export of galvanized sheets increased by 100,000 tons to 595,000 tons. The consumption of the United States, which is one-third of that of the entire world, increased by 8,100 tons in 1910 to 245,000 tons. In consequence of the Zinc Foundries Union putting up the price at the beginning of the year 1910 to M47.25 per 100 kilos for ordinary brands, whereas it now demands M54.50, the prices for zinc goods also rose, and, above all, for galvanized sheets. These cost at the beginning of the present year M57.35 to M59.36 per 100 kilos. In consequence of the action of the German Zinc Rolling Mills Union the price now stands (end of August) at M62.35 to M64.35 at foundry station, according to quantity of goods ordered. As in spite of the high prices the inquiry for zinc finished goods is said to be active the consumers of the raw metal ought to give expression to a strong demand in the near future. The Zinc Foundries Union will in any case do its best not to give an impetus to the price movement, but will pursue a policy suited to the conditions of the market, in order to hinder to the best of its ability any slump on the eventuality of consumption falling off.

STATISTICS AND RETURNS

DOMINION COAL OUTPUT FOR AUGUST.

The Dominion Coal Company's August record of 415,000 tons was 22,000 tons better than any former year.

In previous years June and July were the months when big shipments were made, as the following best month's shipments in the years specified will show:

September, 1902	313,000
July, 1903	273,000
June, 1904	346,000
July, 1905	342,000
June, 1906	362,000
June, 1907	386,000
July, 1908	391,000
June, 1909	393,000
September, 1910	369,000
August, 1911	415,000

The reduction in the coal duty under reciprocity would prove a serious handicap to the company, and if the duty is lowered last month's record will stand unbeaten.

NOVA SCOTIA COAL OUTPUTS.

Nova Scotia Steel & Coal Co., Ltd.

McKinley Dar.	64,250	4,666,759
Nipissing	151,070	4,557,408
O'Brien	.....	1,072,898
O'Brien, M. J.	.....	47,000
Peterson Lake, Little Nip.	.....	58,430
Provincial	.....	151,950
Right of Way	56,980	1,007,895

GOWGANDA ORE SHIPMENT.

The Canadian Mining Journal has been notified that the Miller-Lake Gowganda mine has just completed a shipment of 40,000 lbs. of high grade ore by way of Charlton. Owing to the very bad condition of the Gowganda road it took three weeks to get the ore out to the railroad.

B. C. ORE SHIPMENTS.

The ore shipments and ore milled in the Slocan-Kootenay, Boundary, and Rossland districts for the week ended Sept. 9th totalled 17,255 tons, while the smelter receipts were 14,780 tons. The shipments for the year to date total 1,196,508 tons, and the smelter receipts total 1,096,008 tons. The figures in detail are:

Rossland Shipments.

Centre Star	3,476	139,458
Le Roi	36	10,274
I. X. L.	9	79

B. C. ORE SHIPMENTS.

For the first time for some years the Emma mine in the Boundary, once a heavy shipper to the Hall Mines smelter, last week appeared on the list of shipping mines, 302 tons being received from the property at the B. C. Copper Company's smelter at Greenwood. The shipments during the week ending September 2nd, totalled 17,808 tons, and the smelter receipts were 15,772 tons. The totals for the year to date were respectively 1,159,891 tons, and 1,080,629 tons.

MINERAL PRODUCTION OF GREAT BRITAIN.

The production of minerals in the United Kingdom in the calendar year 1910 has been made public by the British Government.

Coal—The production of coal in 1910 amounted to 264,433,028 long tons, against 263,774,312 tons in 1909. The maximum production of coal was reached in 1907, when 267,830,962 tons were mined. The year of next largest production was 1910.

Iron Ore.—The output of iron ore in the United Kingdom in 1910 amounted to 15,226,015 gross tons, as compared with 14,382 tons in 1909. The maximum production was reached in 1882, when the output was 18,031,957 tons.

Limestone.—In 1910 there were produced in Great Britain 12,736 gross tons of limestone, against 11,811,122 tons in 1909. In 1906 the maximum output of 12,758,,588 tons was reached.

Manganese Ore.—While Great Britain is a fairly large manufacturer of ferro-manganese it is a small producer of manganese ore, its output in 1910 amounting to only 5,467 tons. In 1909 it was 2,768 tons. The maximum production was reached in 1906, when 22,762 tons were mined.

Tine Ore.—The production of tin ore in Great Britain is declining. In 1884 the output was 16,117 gross tons of dressed ore, but in 1910 the output was only 7,562 tons. In the ten years from 1873 to 1882 the average production was 14,114 tons; 1883 to 1892, 14,429 tons; 1893 to 1902, 8,741 tons; and from 1903 to 1910 it was about 7,500 tons.

Zinc Ore.—The production of zinc ore is also declining. In 1910 the output was 11,238 tons, against 9,902 tons in 1909. In early years the average was about 25,000 tons—1873-82, 25,519 tons; 1883-92, 21,931 tons; 1893,1902, 22,182 tons; and 1903-10, about 19,500 tons.

INDIAN GOLD OUTPUT.

The gold production of the mines of the Kolar Goldfield (Mysore) and two outside mines (the Hutti Nizam's and the North Anantapur) for August was 47,730 ozs., an increase of 139 ounces compared with the return of the previous month.

NEW YORK METAL MARKETS.

September 26th—

Tin, Straits, 27.87½ cents.
Copper, Prime Lake, 12.50 cents.
Electrolytic Copper, 12.30 cents.
Copper wire, 13.75 cents.
Lead, 4.50 cents.
Spelter, 6.00 cents.
Sheet zinc (f.o.b. smelter), 8.00 cents.
Antimony, Cookson's, 8.15 to 8.25 cents.
Aluminium, 19.25 to 19.75 cents.
Nickel, 40 to 45 cents.
Platinum, $44 per ounce.
Bismuth, $1.80 to $2 per pound.
Quicksilver, $46.50 per 75-lb. flask.

MINERAL MARKETS.

Acids—
Muriatic, tank cars, $1.15 to $1.55 per 100 lbs.
Nitric, $0.04 to $0.05 per lb.
Sulphuric, $0.01 to $0.01¾ per lb.
Chrome ore, 50 per cent., ton of 2,240 lbs., $15.
Fire clay, $2.50 to $5 per short ton.
Fluorspar, lump, $9 per long ton.
Fluorspar, ground, $12 to $15 per long ton.
Graphite, lump, 4 cents to 10 cents per lb.
Gypsum, short ton ground, $4 to $7.50 per ton.
Magnesite, crude, 95 per cent., $7 to $8.50 per long ton.
Molybdenite, commercially pure, 25 to 30 cents per lb.
Pyrite, lump, arsenic free, 10 to 12½ cents per unit.
Pyrite, fines, arsenic free, 8 to 11 cents per unit.
Tungsten ore, 50 per cent., $7.70 per unit.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining ineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show s of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a ough knowledge of Mining Law, should be very careful with whom they place their business.

DEPARTMENT OF MINES. GEOLOGICAL SURVEY.

PUBLICATIONS

The Geological Survey has published maps and reports dealing wit a large part of Canada, with many local areas and special subject

A catalogue of publications will be sent free to any applicant. A single copy of a map or report that is specially desired will sent to a Canadian applicant free of cost and to others at a nominal price. The applicant should state definitely the precise area co cerning which information is desired, and it is often of assistance in filling an order for a map or report if he states the use for whi it is required.

Most of the older reports are out of print, but they may usually be found in public libraries, libraries of the Canadian Mini Institute, etc.

REPORTS RECENTLY ISSUED:

CANADA

1085. Descriptive Sketch of the Geology and Economic Minerals of Canada. Accompanied by a geological and mineral map Canada, by G. A. Young and R. W. Brock.
1170. Summary Report of the Geological Survey for 1910.

1164. Map 28 A, Sketch map of Portland Canal Mining District.

YUKON and NORTH WEST TERRITORIES

1089. Map 9A. Explored Routes on Parts of the Albany, Severn and Winisk Rivers. Scale 8 miles to 1 inch.

NOTE.—Maps published within the last two years may be had, printed on linen for field use. A charge of 1 cents is made for maps on linen.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economi geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature re ported upon. Letters and samples that are of a Departmental nature, addressed to the Director may be mailed O.H.M.S. free of postage

Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.

BRITISH COLUMBIA

The Mineral Province of Western Canada

as produced Minerals valued as follows: Placer Gold, $71,213,103; Lode Gold, $60,811,067; Silver, $31,095,602; ead, $24,645,605; Copper, $60,743,405; Other Metals (Iron, Zinc, etc.), $1,083,172; Coal and Coke, $114,012,596: uilding Stone, Brick, etc., $10,593,100; making its Mineral Production at the end of 1910 show an

Aggregate Value of $374,197,650.

In 1910 the quantity of Ore mined was 2,216,428 tons, and of coal 3,139,235 long tons. The value of Min- als produced that year was: Placer Gold, $540,000; Lode Gold, $5,533,386; Silver, $1,245,016; Lead, $1,386,350; pper, $4,871,512; Coal and Coke, $11,108,335; Other Minerals, $1,692,473, making the

Total Value for 1910, $26,377,066.

Lode mining has only been in progress for about eighteen years, and not 20 per cent. of the Province has een even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those in any other Province in ie Dominion, or any Colony in the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown rants.

Full information, together with mining Reports and Maps, may be obtained gratis by addressing

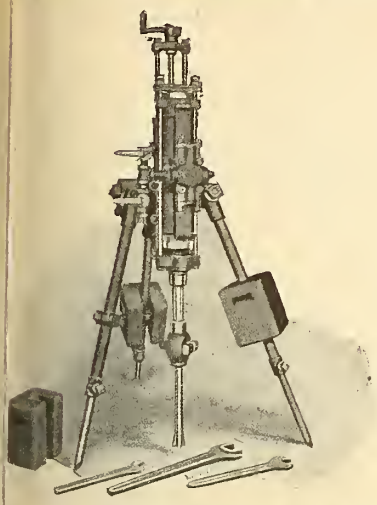
IEW WIZARD ROCK DRILL



We handle the New Wizard Rock Drill, which will drill a greater number of feet per day, per month, or per year, with less power consumed per foot drilled, than any other piston rock drill of like size now manufactured.

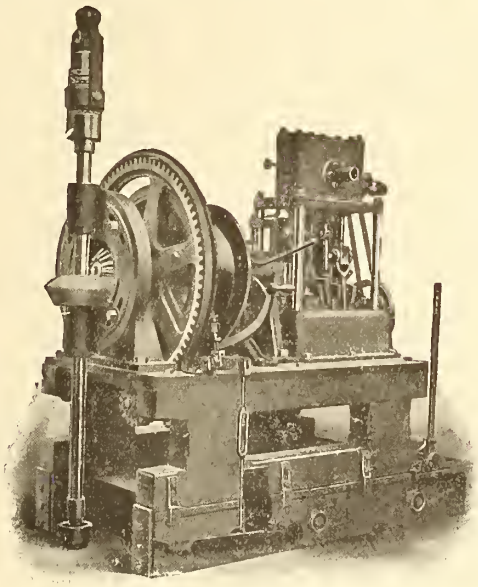
HAMMER DRILLS AND STOPING DRILLS

We handle a complete line of hammer drills and stoping drills for all sorts of mine and quarry work.

Send for information about these drills.

THE TERRY SHOT DRILLS

The Terry Shot Drills vill bore any depth to ;,000 feet; will cut any ize core up to 30 inches.



Will bore at any angle up to 45 degrees; can be operated by steam, gasoline, electricity or air.

Also Air Compressors any type or size.
Pumps any type or capacity.
Hoists, steam or electric.
Boilers, Water Tube or Horizontal Return Tube.
Complete mining and quarry epuipment.

CANADA FOUNDRY COMPANY LIMITED

212 KING STREET, WEST - TORONTO, CANADA

OFFICES AT

IALIFAX MONTREAL OTTAWA COBALT WINNIPEG CALGARY NELSON VANCOUVER

Province of Quebec

Department of Colonization, Mines, and Fisheries.

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, Etc.

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

MINERS' CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10.00 and it is valid until the first of January following. This certificate gives the right to prospect public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his right must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $10 an acre for SUPERIOR METALS when more than 20 miles distant from a railway and $20 an acre when less than 20 miles.

For INFERIOR METALS the prices are $2.00 and $4.00 an acre respectively.

The attention of prospectors is specially called to the territory in the North-Western part of the province of Quebec, north of the height of land, where important mineralized belts are known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, MONTREAL, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The Bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

THE HONORABLE THE MINISTER OF COLONIZATION, MINES, AND FISHERIES, QUEBEC

Nova Scotia Mines

Gold, Coal, Iron, Copper, Lead, Tin, Manganese, Tungsten, and other minerals.

The Gold District covers more than three thousand square miles. Millions of dollars worth of gold have been taken from the gold fields of Nova Scotia and millions of dollar's worth remain for recovery.

Gold mining in this Province offers good inducement for investment. Labor is cheap and plentiful: timber and fuel are abundant.

Large deposits of iron also are known to exist at various places in the Province; and considerable mining has been done in connection with this mineral, the ore being used locally and shipped to foreign ports.

Among the most important minerals occurring in economic quantities may be mentioned, Coal, Gold, Silver, Manganese, Leadsilver, Copper, Barytes, mineral pigments, Gypsum and Tungsten.

Licenses are issued for prospecting for Gold and Silver for a term of twelve months. The licenses are for areas 150 by 250 feet and can be obtained for 50c. an area.

Leases can be secured for $2. an area, for a term of forty years; subject to annual rental of 50c. an area.

Licenses to search over five square miles, for a period of eighteen months, for minerals other than gold and silver, cost $30,

Leases for three renewable terms of twenty years each can be obtained for $50. and are subject to a yearly rental of $30.

Royalties are as follows:—

Gold, two per cent on the gross value thereof; Copper, four cents a unit; Lead two cents a unit; Iron, five cents a ton; Tin and Precious Stones, five per cent; Coal, ten cents on every long ton sold or removed from the mine.

Copies of the mining law can b had gratis, by applying to the Department of Public Works and Mines, Halifax. Nova Scotia, or Mr John Howard, Agent General for Nova Scotia, 57a Pall Mall, London. England.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

THE "ROYAL LINE"

To Europe in

Less than Four Days

LAND TO LAND

The St. Lawrence Route to Europe by the ROYAL LINE shortens the ocean voyage to less than four days, and affords the traveller two days of delightful, sheltered sailing down the great St. Lawrence with its never ending panorama of beautiful scenery and historically famous points. The splendid triple turbine steamers

ROYAL GEORGE and ROYAL EDWARD

hold all speed records and afford the most luxurious accommodation in the Canadian-European service. The English Port, Bristol, is only two hour's run to London by the special boat trains which meet the Royal Line Steamers on arrival.

For further information see nearest Steamship Agent, or the Canadian Northern Steamships Limited.

MINING & SCIENTIFIC PRESS

Controlled by T. A. Rickard | Established 1860 | Published weekly
H. Foster Bain, Editor | Thomas T. Read, Associate Editor

In every issue valuable articles are published on mining, metallurgy, and geology, the latest news from special correspondents at the principal mining centers, letters giving the ideas and experience of successful men, and other items of useful knowledge.

THE MINING MAGAZINE

Established September, 1909
T. A. RICKARD, Editor | Published monthly at London, England

A monthly magazine is the natural corollary of a technical weekly. It permits of more deliberate and more extended notice of matters concerning which the news element is less important.

The Mining Magazine includes a review of the world's progress in mining, metallurgy, and economic geology, written by men who have personal knowledge of the regions and conditions discussed.

COMBINATION RATE: To new subscribers to both papers in Canada U. S. and Mexico, United Kingdom, Other countries in Postal Union — Combination yearly rate $6.00, 7.00, 8.00

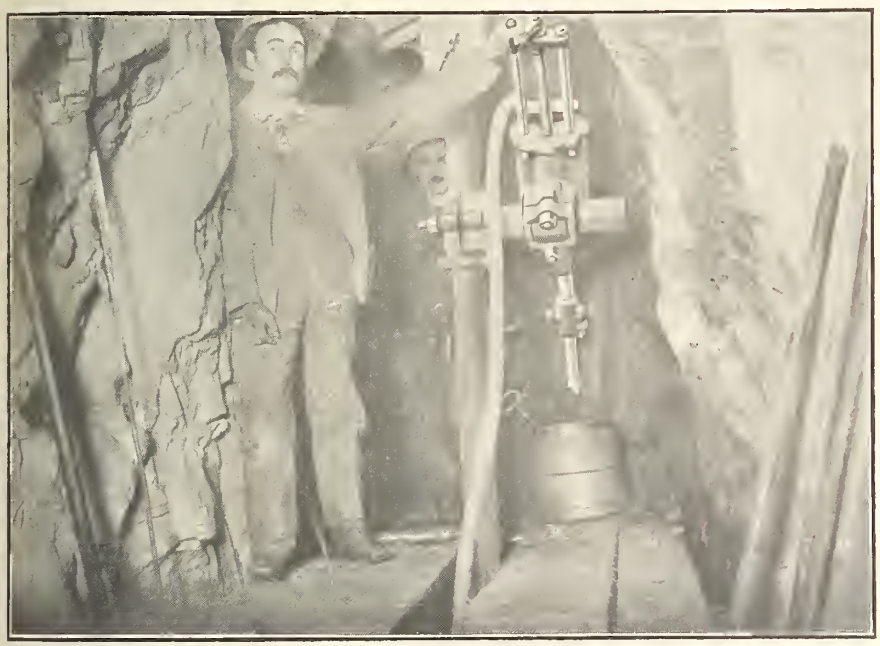
ONE OF MANY

Similar letters which we have received from satisfied users of the

HOLMAN ROCK DRILL.



3½" Holman Air Valve Drill at Temiskaming Mine.

COBALT, ONTARIO,
May 11th, 1911.

Messrs. Mussens Limited,
Cobalt, Ontario.

Dear Sirs,

In answer to your request for our opinion of the Holman Rock Drill, we wish to say that a year ago last April, we put a 3-1/4" machine in the Mine, and against our hardest rock, which is noted for its refractory qualities.

Up to date the repairs on this Machine, or in fact any of them (we now have eight) have been only of a minor character and the amount of rock cut equals in some cases and excels in others, the other makes of percussion machines that we have underground.

Yours truly,
(Signed) R. W Hutchison,
Master Mechanic
Temiskaming Mining Co. Ltd.,
Cobalt.

YOU MIGHT JUST AS WELL BE GETTING THESE GOOD RESULTS.

Increased Footage. Lower Maintenance Cost.

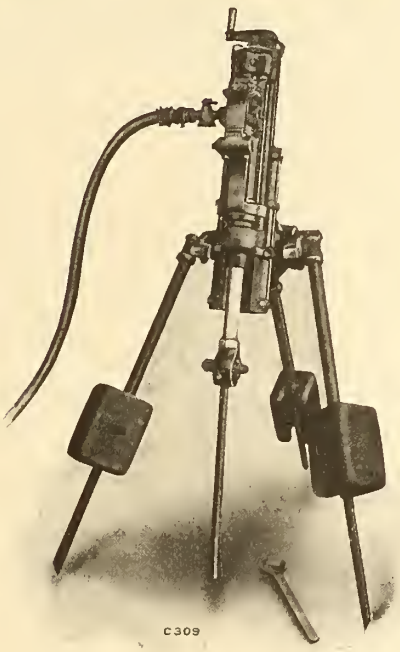
"RAND SLUGGER"

ROCK DRILLS



The Rand Slugger Drill is a successful combination of the positiveness of the rocker thrown valve and the sensitive, economical and quick action of the independent air thrown spool type.

In the "Slugger" design the main valve is thrown by compressed air controlled by a small vertical auxiliary valve, actuated by the rocker which in tnrn is operated by the piston. This device gives a light quick valve motion in which the positive operation of the rocker thrown valve is combined with the advantages of the air thrown spool type.

The "Slugger" strikes a powerful uncushioned blow with lightning like rapidity and although it has only been on the market a comparatively short time, has found great favour among the admirers of the air thrown spool valve.

The substitution of steel parts for those of cast and maleable iron in the construction of this drill means reduced maintenance costs and sustained high efficiency.

The great variety of special materials obtainable and our facilities for special treatment of materials make possible the construction of a highly superior machine which will stand up to continuous rough usage and hard service without rapid deterioration. This design is a thorough exemplification of such construction.

Amatite ROOFING

FOR MINE BUILDINGS

AMATITE is exactly suited to mining buildings because:

1—It can be laid by unskilled labor

2—It has a real mineral surface *which requires no painting.*

3—Its cost is lower than that of other ready roofings of less weight.

4—It comes in rolls ready to be unrolled on the roof and nailed down.

5—The necessary nails and cement are supplied free, packed handily in the centre of each roll.

The mineral surface of Amatite is somewhat of a novelty: and the fact that it obviates the old painting nuisance, is giving to this roofing the leadership of the ready roofing industry.

The surface consists of mineral particles embedded under great pressure into a tough plastic matrix of pitch.

A sample of Amatite will be sent free on request.

Why the C.P.R. North Toronto Route to Ottawa and Montreal is the Logical One

The train leaves as follows:

Leave North Parkdale - - -	9.15 p.m.	Leave West Toronto - - - -	9.30 p.m.
Arrive North Toronto - - -	9.40 p.m.	Leave North Toronto - - -	10.00 p.m.
Arrive Ottawa, 6.50 a.m.		Arrive Montreal, 7.00 a.m.	
Daily.		Double Electric Berth Lights.	

¶ The residents of Toronto are adjacent to either North Parkdale, West Toronto or North Toronto stations, same being easily accessible and close to residential districts.

¶ The North Toronto route is over an hour faster and overcomes a long hill climb for the train out of Toronto obviating any inconvenience and ensuring early arrival at Montreal and Ottawa.

¶ The roadbed has been improved till it is unexcelled in Canada. Practically half the line is double tracked.

¶ The equipment is "Canadian Pacific Standard," a synonym for the "best" and attentive porters, ensure efficient service.

THE TWENTIETH ANNUAL REPORT OF THE ONTARIO BUREAU OF MINES.

The twentieth Annual Report of the Ontario Bureau of Mines has just made its appearance. While its statistics are brought up only to the end of the year 1910, yet there are many pages that include information gathered as late as March of the current year. This palliates the sin of tardiness. However, we can see no reason why the special reports, many of which must have been ready months ago, could not be published as "separates."

In the 301 pages of the Report there are presented many papers of exceptional interest. Inspector E. T. Corkill's chapter on mining accidents is praiseworthily complete. Mr. N. L. Bowen's description of the Thunder Bay silver region will stir up interest in that historic mining country. We quite concur in his belief that the district is worthy of attention. Dr. E. S. Moore, who writes on the Sturgeon Lake gold field, offers a word of warning. He advises against the hasty erection of mills before ore has been blocked out. Prof. M. B. Baker, who was sent by the Bureau to investigate the lignite deposits near the Mattagami River, sums up his opinion thus: "Beyond local use, "confined to the outcrops from which a few tons might "be economically mined, it does not seem that the lig-"nite of the Moose Basin has an economic value." Other papers, all of a high order of merit, are presented. It is, however, with Mr. T. W. Gibson's statistical review that we are presently concerned.

According to Mr. Gibson's official estimate, the value of Ontario's mineral output during the year 1910 was $39,313,895, showing an increment of more than 19 per cent. over the preceding twelve months, and of 53 per cent. as compared with the year 1908. As pointed out by Mr. Gibson, only in one year, namely 1908, has there not been recorded a very substantial gain since 1905.

Although gold is still a very small item in the returns, so impressive are its possibilities that we do not hesitate to deal with it first.

In the past year, only nine mines are on record as having produced gold bullion. These are the Gilmour, in Hastings County; the Havilah, formerly the Ophir, on the north shore of Lake Huron; the Canadian Exploration Company's mine at Long Lake, on the Sault branch of the C.P.R.; the Mikado mine, Lake of the Woods; the LePage and Norwalk, Michipicoten; the Swastika, Otto Township; and the Hollinger and Dome mines, Porcupine.

The total production of these mines amounted to only $68,498. Inconsiderable as this may seem, it must be remembered that a vast change has been effected

in the status of gold mining in the last twelve months. Before Porcupine was exploited, the man who suggested spending money upon an Ontario gold prospect was looked upon as possessing more than his share of temerity. Since Porcupine has begun its spectacular appeal, every corner of Ontario is being searched. Both in the east and in the west old mines have been brought to life. Meanwhile, the pent-up energy of Porcupine itself is about to be expressed in terms of gold bars. Two years ago, the value of the annual output of gold in Ontario reached the low level of $32,445. It may be predicted with safety that in the coming year, 1912, the mines of Ontario will yield at least half a million dollars worth of the much-desired metal. Not a little of this will come from districts other than Porcupine. Gold mining will bulk large in the public eye for some years to come.

Silver, by far the largest single item in either metallic or non-metallic products, was produced to the value of $15,481,322, a figure greater by $3,016,600 than the returns for 1909. To the end of 1910, the mines of Cobalt, Gowganda, Elk Lake, and South Lorrain have sent more than ninety-four million ounces of silver to the markets of the world. During the current year an output considerably larger than that of 1910 is expected. Cobalt has not yet, apparently, reached its zenith. With sixteen concentrating plants at work, and several more projected, it is probable that the production of the camp will be maintained at a high level for a long time. During the year 1910, 305,569 tons of ore were concentrated. The concentrates produced amounted to 7,014.3 tons, carrying 7,084,740 ounces of silver. The average ratio of concentration was 43.5 to 1. It is evident that Cobalt depends in constantly increasing degree upon relatively low-grade ores. The general position of the camp is best indicated by the fact that dividends paid during the year amounted to $7,275,239.90, bringing the total during the life of the camp up to $21,802,179.58.

The Province's output of copper totalled 9,630 tons, a gain of 1,697 tons over the previous year. Of iron ore 230,656 tons were mined, a falling off of $131,901. An increase in the quantity of pig iron is reported. Last year's total was 447,351 tons, whereas in the year 1909, the figure stood at 407,013 tons. Seven electric furnaces, producing iron and steel alloys, are in operation.

Materials of construction, including brick, lime, various stones, Portland cement, and special clay products, were manufactured on a larger scale than before.

The value of arsenic produced was $70,709, an average of only 2.31 cents per pound. It is probable that the market suffers from over-production. Iron pyrites mining, of which 33,812 tons were shipped, more than held its own. Mica, thumb-trimmed, was mined to the value of $85,294. Salt was produced to the amount of 84,071 tons, a very fair gain.

Of the minor products, talc appears to be the mo important. The product of G. H. Gillespie & Co.'s m at Madoc is valued at $46,592, which figure does n by any means represent the real market value.

Feldspar is being mined in larger quantities—16,3 tons as against 11,001 tons. Corundum mining is d cidedly more active. Gypsum, quartz, graphite, a fluorspar show much increased interest.

For the benefit of the complainer, it may be me tioned that the mining revenue of the Province h fallen from $979,464.15 to $941,030.09. The reven for 1911 will be larger.

* * * *

The Report, in its entirety, is a credit to the D partment. Mr. Gibson's summary is a model of caref condensation.

THE STUDENT.

After four or five months of toying with the shov the pick, the hammer, and the drill; or the same tin spent in fighting the man-eating mosquito; or laborio months with the bucking board, the furnace, and t balance; the mining student has arrived with h "wad" to take up for another year the routine college.

He is a wiser and weightier personage than he w last spring. Physically he is tougher. Morally a intellectually he is more developed. If he is ente ing on his last year, he is prepared to look with hosti eye upon the crude sophomore and the frivolous fres man, and with critical tolerance upon his professor He has been up against the real thing, and he cham his bit. O, for next spring! Oh, for the freedom th graduation brings!

Eight months of hard work will temper this fi autumnal enthusiasm. The pale graduate that eme ges next year will need no curb. He will find that bi lets do not hang on every bush. There is room f him, but he must squeeze and push and shove.

Meanwhile let him take heart of grace. The pe centage of mining men that fall by the wayside is lo There is no need of increasing the number. Imp tience, lack of actual preparedness, and the desire f soft snaps are the three main causes of failure.

To-day the horizon of the mining man is wider, a must remain wider. Even through the four years college the student can prepare himself for broad citizenship than is implied by mere technical wor Even in the loneliest mining camp the young gradua need not rust. His interest in professional matte in general reading, in politics, and in progress shou remain unabated. Narrowness is to be avoided. is deadly.

One specific against dry-rot, one cure for the blue is letter writing. Within proper limits, a large co respondence is invaluable. The act of writing clea the mind, and exercises and stimulates the ment faculties. A regular and methodical record of wo

one, of methods used, of mistakes, and of successes, akes the days and months of early labour infinitely ore interesting and valuable. A man's career thus ecomes an organic and coherent whole, instead of a isconnected series of incidents.

* * * *

The CANADIAN MINING JOURNAL extends to the min-ng student its heartiest good wishes. May the ses-ions of 1911-1912 be more instructive than ever before.

THE ENGLISH STEEL INDUSTRY.

Bound by conditions imposed by the International teel Rail Syndicate, English rail manufacturers are acing a grave situation. The Syndicate is composed argely of Great Britain's competitors. By mutual greement, no quotations are made below certain fig-ures. In itself this is a sane arrangement. Unfor-ortunately the Syndicate does not now control the vorld's production. In the year 1907 it had practi-ally all the large producers in a solid phalanx. Since hat year, however, large independent concerns in Canada, the United States, and Russia have come into he international market. These new unfettered com-petitors have brought about a condition that imperils very seriously the steel trade of England. This will e understood when it is stated that Russia has sent ails to Ireland, and Canada has filled contracts in England. England, in other words, is prevented from poaching, but is forced to suffer it.

During the immediate past England's steel trade has been steadily losing ground. Germany, the United States, and Belgium have gained ground. Fourteen years ago England exported about 600,000 tons of steel rails; last year she exported only 435,000 tons. This is true despite the fact that English manufacturers have modernized their plants in every respect.

Present circumstances show that Judge Gary's suggestion of world-wide syndication will hardly appeal to England. The present agreement expires in March next. Until then the English manufacturer must be content to see his rivals forge ahead whilst he remains in statu quo. After the expiry of the syndicate agreement it is highly improbable that England will do anything but hoe her own row, and mind her own business without reference to her competitors.

SICILIAN SULPHUR.

Including the island of Sicily, there are in Italian territory more than 400 producing sulphur mines. Of a total annual output of crude ore exceeding 2,800,000 metric tons, Sicily is credited with more than 2,600,000.

The Sicilian sulphur occurs in argillaceous limestone, associated with gypsum and bituminous marl. The crude ore is brown or yellow in colour. The indication sought for by the miner is the presence of "boiscale," a yellow, porous, crystalline alteration product resulting from the oxidation of the sulphur and the action of the sulphuric acid thus formed upon the limestone.

The crude ore contains 25 per cent. of sulphur. Extraction is simple. The ore is burned in beehive ovens, or in "calcaroni"; or it is treated with superheated steam. Three grades of sulphur are exported, the first being practically pure, and each of the two other grades being thrown into three sub-grades—"vantaggeata," or best; "buona," or good; and "corrente," or current.

The effect of the competition offered by Louisiana is seen when it is noticed, that in 1902, the United States and Canada imported about 177,000 metric tons of sulphur from Sicily, whilst in 1909 the imports were only 16,972 metric tons.

MR. THURBER, REDIVIVUS.

An indignant correspondent, evidently a loyal friend of Mr. Thurber, writes us to the effect that we have wrought gross injustice upon that long-suffering person. The accusatory letter has been printed in full on another page. A little explanatory comment will not be out of place.

About two years ago, or more, Mr. Thurber induced some citizens of Kenora to back financially his efforts to extract more gold from ores and rocks than nature had placed there. Or, to put it more fairly, Mr. Thurber asserted that all modern methods of gold extraction, including even the fire-assay, were incomplete and inaccurate, and that he himself could obtain several times the amount ever obtained by ordinary workers. Naturally Mr. Thurber failed to substantiate his claims, although he was given every chance.

Now he has former an unholy alliance with a stock-jobbing concern in Winnipeg, and again his process has been advertised.

Our correspondent inveighs against us for our narrowness in refusing to encourage a worthy inventor. Our attitude is attributed to professional jealousy. He makes the mistake here of thinking that any inventor who works in the dark and also aids in bleeding the public can be taken seriously. If Mr. Thurber's process is revolutionary it is also patentable, so that even did we wish to misappropriate his invention it would hardly be feasible to do so. It must be confessed, however, that our time is pretty fully occupied with our various duties. Reasonable doubts exist in our editorial mind that we would swipe Mr. Thurber's secrets in any circumstances. The temptation does not touch us on a weak spot—otherwise the inventor might possibly not be safe. As matters stand, we can assure both correspondent and inventor that they can put everything on the table without danger. We shall go farther. We shall guarantee to have Mr. Thurber and all his heirs and assigns pensioned comfortably for life if he can show the goods. This is not a costly offer. Ourselves also would be furnished with a much-needed bank reserve.

ADVERTISING.

Just how far and in what manner the mining engineer should keep his name before the publie is a mueh-debated point. In times of aetivity, the engineer who has to do with companies whose stoek is being pushed finds himself subjeeted to advertising that is objeetionable. Often this eannot be prevented. The vietim is immolated upon the shrine of the stoek market.

The ease is quite different, however, when the engineer designedly exploits himself in the newspapers. Apart from all questions of good taste, the newspaper puff is immoral. It appeals only to those who have no knowledge of the standards by whieh the mining engineer is judged.

Brief notiees in the public press of movements and engagements are to be eommended. In these days it is necessary to keep one's name before the reading publie. Anything beyond this is to be frowned upon. The engineer is not a merehant selling his wares Professional etiquette forbids him to enter into eommereial, rate-eutting eompetition with his fellows. And it also should prevent him from displaying himself in type.

In Canada there is far too mueh of this form of vulgarity. Ostraeism is the only suitable penalty. The self-respeeting engineer does not need to eireulate inflated praise of his aeeomplishments.

THE TRANSLATION OF MR. COCHRANE.

It is with unqualified regret that we note the removal of the Hon. Frank Cochrane from the Ontario Department of Mines. For six years Mr. Coehrane has administered the Department of Lands, Forests, and Mines, a billet that is by no means a sineeure.

Whatever faults can be found with Mr. Coehrane's direction of mining affairs in Ontario ean be attributed to honest errors of judgment. No shadow of doubt exists that he was sineerely anxious to do his duty. Brusque, outspoken, and sometimes a trifle too ready to loek horns he undoubtedly was. These qualities may be regarded as virtues when eontrasted with the smooth adaptability of the professional politician.

During the last eleetion eampaign Mr. Coehrane displayed a genius for effeetive organization. So important a part did he play that Mr. Borden felt that not only was high reeognition neeessary, but that Mr. Coehrane should become one of his fixed advisers.

As Minister of Railways Mr. Coehrane will have a ehanee for showing what he is. While we are sorry that he was not plaeed at the head of a new Department of Mines, we ean honestly eongratulate the Premier upon having Mr. Coehrane assoeiated with him.

EDITORIAL NOTES.

The alleged diseovery of plaeer gold in Baffin's Land by Messrs. Elmsley and White has roused eonsiderable eomment. It has not yet reeeived suffieient eertifiea-tion to be taken as aeeurate.

It is the intention of the Provineial Workmen's A sociation to ask that all eoal eutting maehines run b eleetricity be removed from the eollieries of Nova Sc tia. The ground of complaint is the inferior capaci of sueh maehines as eompared with those run by co pressed air.

For the total loss of his sight, Peter Collins, an e ployee of the Britannia Mining and Smelting Co pany, B.C., was awarded $9,000. In his eharge to t jury, Judge Morrison stated that whilst an employer not an insurer of his employees, yet he must adopt a reasonable preeautions to ensure their safety. An e ployee is not an inspector of his employer's plant.

A Toronto newspaper lately printed in its "Want eolumns the following advertisement:

"Will pay for information if you know of an "one who has made money in mining. You "name not mentioned. Box — —"

This typifies the average lay mind. The easual eit zen learns his mining on the stoek exehange. H takes a prospeetus to heart. When roseate promise turn to ashes he blames the industry, instead of ehas ening himself. The advertiser, had he known augh of mining, would have known some dozens of name representing men in Toronto alone, who are reeeivin legitimately earned dividends from mining properties

Personal and General

Mr. Howard W. DuBois, managing direetor of th Quesnelle Hydraulie Gold Mining Company, has bee spending a vaeation in the Canadian Roeky Mountain Park, after having seen in full operation the big wate supply system be designed and had eonstrueted fo his company in Quesnelle mining division, Cariboo dis triet, British Columbia.

Mr. John Hopp, who operates several hydraulic pla eer-gold mines in Barkerville distriet, Cariboo, wa in Vietoria about the end of September.

Mr. W. H. Trewartha-James, of Vietoria, B.C., gen eral manager of the Tyee Copper Company, left Bri tish Columbia late in September on a business visit t the East, as far as New York.

Mr. W. L. Coulson, manager of the Canadian Col lieries (Dunsmuir), Limited, has been in the eastern States lately.

Mr. W. M. Brewer, now manager of the Matanuska Gold Mines, developing a lode gold mining property in Alaska, was down from the North reeently, on a visit to the Coast cities of British Columbia.

Mr. H. M. Ridge, a well known speeialist in the treatment of silver, lead, zine, and other base metals has left British Columbita on his return to London after having spent a week examining mines in the vicinity of Slocan Lake.

Mr. H. M. Davys, managing direetor of the Silverton Mines, Ltd., operating the Hewitt-Lorna Doone group of mines, and the Wakefield mill, in Silverton eamp, Slocan Lake, has returned to his home in England after having spent several weeks in British Columbia

Prof. John Cadman, D.Sc., professor of mining at Birmingham University, England, was at Bellevue, Alberta, a short time ago. Beside having contributed several important papers to the Institution of Mining Engineers, the professor three or four years ago was engaged in special research work for the Royal Commission on Mines.

Mr. Thomas Kiddie, Vancouver, B.C., has been making enquiries for the Government of British Columbia into the question of an intended increase in the charge for electric power, notice of which has been given copper mining and smelting companies operating in the Boundary district of British Columbia, which companies appealed to the Government against such increase in rates by the company supplying the power.

Mr. Martin Nordegg sailed from New York for Europe on October 8th.

Mr. Hector McInnes, one of the directors of the Dominion Steel and Coal Company, was in Toronto early in October.

Mr. Norman Fraser, formerly superintendent of the Michel Collieries of the Crow's Nest Pass Coal Company, was in Toronto on business on October 5th and 6th, when he left for Ottawa. Mr. Fraser is connected with Rocky Mountain Collieries, whose head office is in this city.

Mr. L. D. Huntoon, for the past seven years professor of mining and metallurgy at the Sheffield Scientific School of Yale University, has opened offices at 42 Broadway, New York, for the general practice of mining engineering. Mr. Huntoon will be remembered by many Canadian friends who met him on the A. I. M. E. excursion to Sudbury and Cobalt in the summer of 1908.

Mr. F. G. Stevens, mining engineer, 404 Albert St., Kingston, Ont., left on October 6th for Mexico. He will return at an early date.

Mr. Harold Kingsmill has resigned the office of general manager of the Rea mine, Porcupine. Mr. Kingsmill has been in charge of the Rea almost from the first. He is to take over the management of a South American mining property.

CORRESPONDENCE

To the Editor of the CANADIAN MINING JOURNAL:—

Sir,—Your excellent journal is, I believe, devoted to maters of vital interest to the mining as well as to the scientific world, and there are, I am sure, many thousands of your readers who hail its coming with delight.

A copy of your journal occasionally falls into my hands, and I must admit that I peruse its pages each time with much interest.

Your aim is, Sir, to keep abreast of the times in so far as the conduct of your journal is concerned, and for this your many readers will no doubt commend you.

But, Sir, when you mar your editorial pages with criticisms of an unwitting character, you are really slipping away from the goal towards which you strive. A newspaper's character, they say, can be determined by its editorials.

Mr. Thurber, of Kenora, has been the subject of your remarks on two different occasions, and it seems to me that had you taken the trouble to find out a little more about this much abused gentleman and his process before trying to cross swords with him, your better self would have recoiled with feelings of disgust and revulsion. [Editor's Note:—Sic.—]

You have made your journal responsible for harbouring and giving vent to sentiments which should be altogether foreign to it, which are far from being creditable to either yourself or the journal over whose destiny you rule.

Like many inventors who brought light to the wirld, Mr. Thurber is having his struggles and up-hill work. He is not being encouraged and helped along as he undoubtedly deserves to be; on the contrary, he is put down as one whose company should be shunned; as a man who is trying to foist his fool invention on a long-suffering public.

This experience, of course, has been the lot of many others who have made good, and, notwithstanding your criticisms to the contrary and your efforts to wither Mr. Thurber out of existence, I have very substantial reasons to know that the "Thurber process" will in the near future surprise not only yourself but the whole mining world. [Editor's Note:—We have no doubt on this point.]

Mr. Thurber has contented himself so far by completely ignoring his enemies; he works away quietly and unassumingly, and it is doubtless this attitude, combined with his dogged persistence and "stick-to-itiveness" which gall those jealous busybodies and slanderers who had better look to their own foul doorsteps before even attempting or daring to criticize a gentleman whose shoe strings they are unworthy to tie.

In conclusion, I would offer the remark that the attitude assumed in many parts of the country towards the Thurber Process is doubtless due to the knowledge that present-day methods of extracting gold from ores must sooner or later give way to a simpler and better one.

Can you, Sir, give your readers any plausible reason, based on scientific facts, why the Thurber Process should not fill the bill?

Yours truly,

T. SCOTT CAMPBELL.

Pine, via Vermillion, Ont.
Sept. 25th, 1911.

BOOK REVIEWS.

THE COPPER HANDBOOK, Volume X, 1910-11—A Manual of the Copper Industry of the World — Compiled and pubulished by Horace J. Stevens, Houghton, Mich., U.S.A. 1911.

Volume X., the tenth edition of the Copper Handbook, has just been received. The new issue of this work, which is considered a standard authority on the subject of copper and copper mines for the entire globe, has 1,902 octavo pages, containing nearly 1,500,000 words. In addition to the miscellaneous chapters, it lists and describes 8,130 copper mines and copper mining companies, in all parts of the world. This is the largest number of titles ever listed by any work on mining. The descriptions range from two or three lines, in the case of dead companies, wherein reference is made to detailed descriptions in past volumes at the period of their activity, up to 21 pages in the case of the Anaconda mine, which yields one-eighth of all the copper made in the world.

The miscellaneous chapters of the book, 24 in nu- ber, treat the subject of copper from all possible vie- points, there being chapters on the history, chemist mineralogy, metallurgy, brands and grades, alloys a substitutes for copper, with a copious glossary, a a chapter of statistics ending the book that conta 40-odd tables, thoroughly covering copper producti consumption, movements, prices, dividends, etc. T Copper Handbook is sold on the unique plan adopt nine years ago. The publisher sends the book mail, prepaid, to any address ordered, without advan payment of any sort, and subject to return after week's inspection. The price is $5 in a strong gre buckram binding with silk headband and gilt top, $7.50 in full library morocco. Anyone interested copper, as a producer, consumer, or investor in shar would do well to write the author and publisher, M Horace J. Stevens, Houghton, Michigan, ordering copy of the new Copper Handbook sent prepaid, su ject to approval.

Application of Electricity in the Metallurgical Industr of Italy.

[Specially abstracted for the Canadian Mining Journal from a paper by R. Catani (Rome), read before the Iron and Steel Institute.]

This paper discusses the production of steel by electricity; the smelting of pig iron by electricity; and the production of alloys of iron with other metals by electricity.

I. Production of Steel or Iron in the Electric Furnace.

In Italy steel is manufactured in the electric furnace either direct from ores or from iron products. The first experiments in the direct production of steel from ore in the electric furnace were made at Rome by Stassano in 1898.

A. Steels Produced Direct from Ore.—The problem of the direct reduction of steel from iron ores, using coke or coal as fuel, has not been solved by old methods on a commercial scale. But the results of a few years' trial with the electric furnace have surpassed expectation. In due time, it may now be affirmed with certainty, the problem of producing steel by a direct electric process will have been overcome.

In Stassano's experiments at Rome the material was first crushed, pressed into briquettes with tar, and finally treated in the electric furnace. Recent trials have shown, however, that it is equally easy to treat the ore in a fine state or in lumps, and hence briquetting can be dispensed with. Because he adhered too closely to blast-furnace practice, both in regard to the shape of the furnace and the process itself, the first experiments of Stassano led to no practical results. The first furnace used at Rome, 1898 to 1899, was a shaft furnace in which, instead of having tu eres, electrodes were provided for conducting electr current. The ore was arrested by means of a gratin at a distance of about 20 centimetres above the ele tric arcs.

Finally Stassano adopted a furnace of the heart type. The principal characteristics were that it wa roofed over, and long electric arcs played between th mass of the charge and the arch of the furnace. Th arcs swept the surface of the slag without passin through it. The heat, therefore, passed indirectly int the bath by radiation. The electrodes had a high den sity, and were held in water-cooled supports. Th furnace was completely closed in, and the gase evolved were collected and carried off.

Some Stassano furnaces are fixed, others can be ro tated. In some the only rotary movement is that o tilting towards the side of the tapping hole so as t facilitate tapping. Others can be rotated on the vertical axis so as to stir the bath. Single-phase cu rent with one or more pairs of electrodes or three phase current can be used. Stassano's experiments fo the direct production of steel may be divided int two groups, namely, those performed during 1898-190 the results of which were published in March, 1902 and those the results of which were published in 190

In the first trials only hematite ore of first-clas quality, from the island of Elba, was used.

The analyses of the ore, charcoal, pitch, limestone and product follow:—

Ore.	Per cent.
Fe_2O_3	93.02
MnO	0.619
SiO_2	3.790
S	0.058
P	0.056
CaO+MgO	0.500
Moisture	1.720

Quantity used per 100 kilogrammes of steel produced: 165.8 kilos.

Charcoal.	Per cent.
C	90.42
Ash	3.88
Moisture	5.70

Quantity used per 100 kilogrammes of steel produced: 26.5 kilos.

Pitch.	Per cent.
C	59.20
Hydro-carbons	40.50
Ash	0.27

Quantity used per 100 kilogrammes of steel produced: 20 kilos.

Limestone.	Per cent.
CaO	51.21
CO_2	43.43
MgO	3.11
Al_2O_3 } Fe_2O_3 }	0.50
SiO_2	0.90

Quantity used per 100 kilogrammes of steel produced: 119.1 kilos.

Average product.	per cent.
Fe	99.7
C	0 10
Mn	0.10
Si	0.10

Quantity used per 100 kilogrammes of steel produced: 100 kilos.

Altogether there were produced only 125.6 kilogrammes of steel. The loss of iron was about 8 per cent. The consumption of energy averaged 4187 kilowatt hours per ton of product, and the mean efficiency of the furnace was 48 per cent. The electrode consumption was estimated at 12 kilogrammes per ton produced.

The industrial importance of the process was insignificant, as only first-class material could be used, the cost of preparation was excessively high, and the energy consumption prohibitory.

In the second series of his experiments, Stassano used an ore of the following composition:

	Per cent.
Fe_2O_3	68.70
Mn_3O_4	3.23
SiO_2	17.15
Al_2O_3	2.
CaO	1.
MgO	5.67
P	0.15
S	0.12
(Fe	48.09)

The ores were again crushed and briquetted, but with a 25 per cent. solution of silicate of soda instead of with pitch. Steels of good quality were obtained, the analyses of the product of charges Nos. 2 and 4 being given herewith:

	Charge No. 2.	Charge No. 4
C	0.26	0.80
Mn	0.21	0.30
Si	0.03	0.22
P	0.010	0.015
S	0.040	0.045

In this second series of experiments, in which only four charges were worked, particulars were not given either of the total production or of the consumption of electrode, or of the composition of the limestone and the charcoal. The furnace was of 200 horse-power, with three-phase current, and the average consumption of electric energy was 4,250 kilowatt hours.

The charges were as follows:—

	Kilogrammes.
Ore	100
Limestone	35
Charcoal	24
Aqueous solution of silicate of soda	8
Carbide of calcium	5

Assuming that the loss of iron was the same as before, namely, 8 per cent., the consumption of material per ton of steel produced would have been:—

	Kilogrammes.
Ore	2250
Charcoal	540
Limestone	787
Silicate of soda	180
Carbide of calcium	112

In addition, it is calculated that, in these last experiments, the furnace consumed, for every ton of steel produced, about 50 cubic metres of water for cooling the holders of the electrodes.

B. Steels from Iron Products.—With the electric furnace, however, the general practice is to use pig iron instead of ore, in which case the material can be charged into the furnace in either the liquid or the solid state. The following table shows the approximate power consumption when different materials are used.

Kilowatt hours necessary for producing a ton of steel

	Kilowatt hours.
From cold pig iron	1500
From liquid pig iron	1100 to 1200
From cold pig iron and cold scrap	900 to 1300
From liquid pig iron and cold scrap	600 to 1000
From cold scrap	300 to 900

Refining.

	Kilowatt hours.
Steel of crucible quality from liquid iron	200 to 300
Ordinary electric steel from liquid form	120
Mixer	50

1. Cold Charging. — The raw materials consist generally of pig iron, scrap, ore, and additions.

The first installation of the Stassano furnace was made at the Royal Artillery Works at Turin, by the Italian Ministry of War in 1903. The furnace is of 200 horse-power. Subsequently the Stassano Electric Furnace Company established an electric steel works at Turin. Following are the general specifications:

No. of furnaces	2	2	2
Horse power	100	200	1000
Volts	75	100	150
Amperes	1000	900	2700
Kind of current	Single-phase	3-phase	3-phase

Three-phase current at 21,500 volts was supplied by the Societa Anonima Elettricita Alta Italia, and this

was stepped down by special transformers to 75, 100, and 150 volts for the furnaces of 100, 200, and 1000 horse-power respectively. The single-phase furnaces of 100 horse-power were shunted, on a single-phase circuit. The current supplied to the furnaces amounted to about 350 kilowatts from December to March, and to 800 kilowatts from March to December, while the total power of the furnaces was 2,600 horse-power= 1910 kilowatts. The Turin works of the company manufactured chiefly parts of railway carriages, wagons, and automobiles. The company went into liquidation in 1909. Some of the furnaces of the Turin plant have been transferred to the works of the Elba Company at Portoferraio and some to the Milan Steel Works.

The Stassano furnace installed at Portoferraio now works with cold charges; but it is probable that the company will soon adopt liquid charging for the production of high-quality steel. The installation at Milan is not yet in operation.

Heroult furnaces are installed in Italy at the works of the Mannesmann Tube Company, formed by the amalgamation of the Mannesmann Tube Works at Dusseldorf and of the Metallurgical Company of Rome. The works are situated at Dalmine in the district of Sabbro, Province of Bergamo. Three-phase current is delivered at the central station at 12,000 volts, where it is transformed to 550 volts. There are two furnaces in which open-hearth steel scrap is melted. Both furnaces are in operation.

One Girod furnace is in course of construction at the steelworks at Cornigliano Ligure of the Giovanni Ansaldo Company. It is three-phase of 350 kilowatts at 50 cycles, with a capacity of 4 to 5 tons. The material is charged cold, the maximum potential between phases being 70 volts. The furnace is intended for the manufacture of special steels only. When operated with liquid charges the production will be increased by about 40 to 50 per cent.

Electric furnaces may be charged either with liquid pig or with steel from the converter, or the acid or basic open-hearth. With liquid steel a simple refining process only is required, and, by the removal of occluded gases, the quality is much improved.

The first furnace worked with liquid charges in Italy was the Kjellin furnace installed at the works of the Giovanni Andrea Gregorini Steel and Iron Foundry Company at Castro on Lake Isco. It is now working on liquid steel taken from a 4-ton open-hearth furnace, which supplies to the electric furnace 1400 kilogrammes of metal at each heat. The steel supplied has the following composition

Carbon, 0.08 to 0.10; silicon, 0.03 to 0.05; sulphur, 0.010 to 0.020; phos., 0.008 to 0.015; mang., 0.18 to 0.35.

The final product contained: Carbon, 0.60; silicon, 0.25; manganese, 0.12.

The recarbonization was effected by adding pig iron. The furnace is tapped every 2½ hours, yielding at each heat 1400 kilogrammes of steel. Thus the daily production amounts to about 15 tons. The steels produced, whether hard or soft, are always very malleable.

The Kjellin furnace in question is a simple induction furnace taking 300 kilowatts. It is supplied with single-phase current at 25 cycles. When working on cold charges the production is about 10 tons daily, the energy consumption being 690 kilowatt hours per ton of steel produced. The patent furnace lining of the Poldihutte is used, which lasts for about 120 hea. High speed steel can be manufactured carrying 25 p cent. of tungsten and 6 per cent. of chromium.

II. Production of Pig Iron in the Electric Furnac

In the Canadian experiments conducted by Dr. P gene Haanel, and in the successful industrial effo of Swedish manufacturers, ordinary grades of iron o were used. In Italy experiments have been carri out by Carcano for the production of pig iron fr pyrites residues. Purifying, enrichment, and a glomeration are necessary to prepare pyrites residu for treatment in the blast-furnace. The material oft carries more than 4 per cent.

The residues treated by Carcano in the electric fu nace contained:

Silica	From 7.9	to 12.25	per ce
Iron.....	From 47.0	to 60.3	per ce
Alumina	From 6.9	to 18.80	per ce
Sulphur	From 2.01	to 4.25	per ce

The residues were charged in their powdery con tion. It was endeavoured to work with the most bas slag possible, with a certain percentage of manganes so as to ensure a sufficiently strong desulphurizing e fect. Generally, manganese is found to be a satisfa tory desulphurizer. In the experiments raw materi containing up to 4.25 per cent. sulphur yielded a p iron running between 0.015 and 0.058 per cent. su phur in the presence of from 2.17 to 2.54 per ce manganese. Various types of electric furnace of di ferent powers were used. The furnace tried by Ca cano in 1908, which gave the most favourable result was of a capacity varying frob 200 to 300 horse-powe It was aclosed furnace with neutral hearth supplie with single-phase or three-phase current with aut matic charging, and with recovery of the carbon mo oxide evolved during the reactions. That gas w used to prevent deoxidation of the pyrites residue The energy consumption per ton of pig produced ave aged 2100 kilowatt hours in a furnace of 180 kil watts and using residues containing 50 to 55 per cen of iron in the form of ferrous oxide. The lower end of the vertical electrodes rested on the slag, so tha the furnace worked as a surface resistance furnac and the slag was of very high temperature, muc above that of the bath. By this means it was possibl to obtain highly fluid slags sufficiently basic in cha acter.

Too many data are lacking to make it possible t present a practical estimate on the economic aspect o the process.

III. Ferro-Alloys.

The chief metallurgical products manufactured i the electric furnace in large quantities are ferro-a loys. Such alloys as ferro-manganese and ferro-sil con low in silicon, were known before the introductio of electric smelting; but with the electric furnace i is possible to produce alloys with a very much lowe carbon content than before. The production of suc alloys as high grade ferro-silicon, ferro-chromium, fer ro-tungsten, is practicable only in the electric furnace and these are manufactured either from the ores them selves, or direct from the metals, or from the metal and ores together. The only ferro-alloy electrically manufactured in Italy on an important scale is that o ferro-silicon, of which 628 tons were produced in 1909 Some experiments in other directions may be briefly mentioned.

A. Ferro-Alloy from Ores. — The author of this pa- r has made experiments for the purpose of studying e economic possibility, under given conditions, of oducing ferro-silicon by smelting silieates of iron or n ores too highly silieeous for treatment in the ast-furnaee: also east iron or pig iron that has been jeeted on aeeount of its high sulphur or phosphorus ntent. The eleetrie furnace used was speeially modi- d by the author. It was marked by the absenee of y kind of flexible eonductor. A minimum quantity current passed through the eonduetors and through e eleetrodes; a minimum spaee was taken up by the nduetors; and water-eooling was eonfined to those rts of the furnace above the plane of the eleetrie es. These furnaees have a high total efficiency, and n be adapted to the manufacture of ealeium car- ide. With alternating eurrent the power factor ap- proaches as near as praeticable to unity. The current supplied is of 12,00 amperes at 42 volts 25 eyeles.

B. Ferro-Alloys from Metallurgical Products.. The greater part of the ferro-silieon manufactured in Italy is produeed from quartz and scrap iron. The first works in Italy that manufactured on an industrial seale were those of the Societa Elettroehimica at Bussi. The produetion in 1907 was 175 tons; in 1908, 808 tons; and in 1909, 606 tons.

In 1909 the Piedmontese Company for the Manufacture of Carbide of Caleium and Allied Products produced 22 tons of ferro-silicon. The electric furnace used for smelting ferro-silicon is absolutely identical with that used for the produetion of earbide of ealeium, and works with the same eurrent at the same pressure.

RESEARCH WORK ON CERTAIN NOVA SCOTIAN GOLD ORES.

By Ora Willis Knight, M.Sc., D.Se., Bangor, Maine, U.S.*

(Continued from Oetober 1st issue.)

Arsenopyrite, pyrrhotite, pyrite, and other preeipi- ants of gold are generally distributed throughout raetieally all of the bedded veins, and well defined late partings whieh are also eapable of precipitating old exist above and below the quartz of these bedded eins, as well as often mingled with the quartz, so it s quite evident that any gold passing through the edded veins in solution should have been preeipitated herein sooner or later. Over a hundred assays made y me on material taken from bedded veins, at con- iderable distanees from fissures, have failed to show he presenee of gold in paying quantities, the gold alue found being from 40 to 67 eents per ton of ore. The conclusion seems eertain that the bedded veins so sampled, all being on or near antielinal axes, had not served as trunk channels for gold-bearing solutions.

A number of assays made of ore taken from near fissure veins, but on bedded veins, gave gold values ranging from $1.50 up to hundreds of dollars per ton of ore, indieating that better gold values were present near the fissure veins whieh are eommonly known as "angulars" in Nova Seotia.

As there seems to be a well developed opindion among the miners of the province that the presenee of troughs in the wall above the vein, or the presence of the so-called barrel rolls of quartz are indieations of pay-ore and are generally eonsidered infallible, I wish to say that samples taken in several plaees where these conditions were prominent gave assay returns averaging 67 eents in gold to the ton of ore.

Although, of eourse, it is possible that in eertain districts there are bedded veins whieh were aetually trunk ehannels for gold-bearing solutions, it is my purpose to elaim that the fissure veins or angulars, or in other words veins eutting aeross the strata either in extent or in dip, were the main trunk ehannels for the gold-eontaining solutions. Fissure veins passing aeross quartzite formations would encounter the conditions most favourable to precipitation of gold at such places as they either passed through slate formations, passed through or interseeted bedded veins, passed through quartzite containing pyrites, or other preeipitating gold or solutions themselves bearing gold and eapable of precipitation by the material in the fissures entered.

Where a fissure vein, earrying gold-containing waters, intersected a bedded vein full of precipitating material there would be formed a pay-shoot, often extensive, along the general line of intersection, or sometimes merely a loeal enrichment of nuggety gold, according to existing eonditions. Under sueh eonditions extensive pay-shoots were formed in many instances, and doubtless extend to great depths along the line of interseetion.

The interseetion of a fissure with a bedded vein, under eonditions highly favourable to the precipitation of gold, may result in so completely throwing down the gold along the area of eontaet that there is not sufficient gold left to be precipitated and form pay-shoots at the intersections of the fissure with other veins more or less vertically above it. Under sueh conditions no profitable body of ore would exist above sueh a pay-shoot, but at a suffieient distance one way or the other along the fissure, where the dip of the bedded vein would take it down and out of the field og influence, other pay-shoots would be formed on other bedded veins.

Similarly where fissures passed through slaty strata or other formations capable of eompletely precipitating gold, the gold would form more or less extensive pay-shoots along the line of interseetion, and no pay-ore would oeeur beyond until other preeipitating ageneies are passed through.

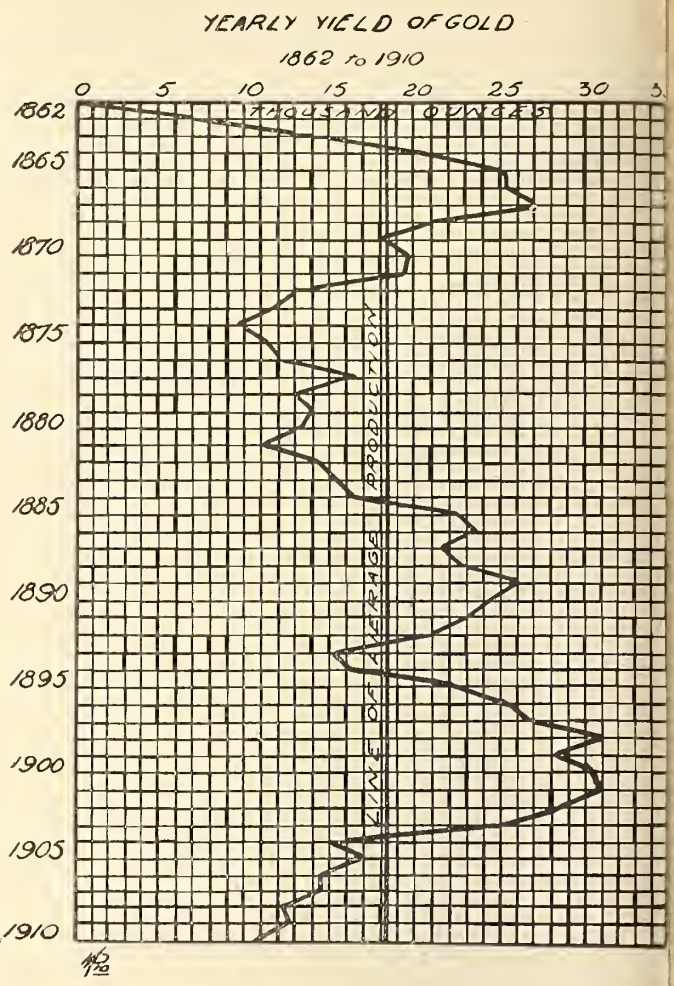
Where fissures were intersected by other fissures at various angles, the one earrying gold-containing solu-

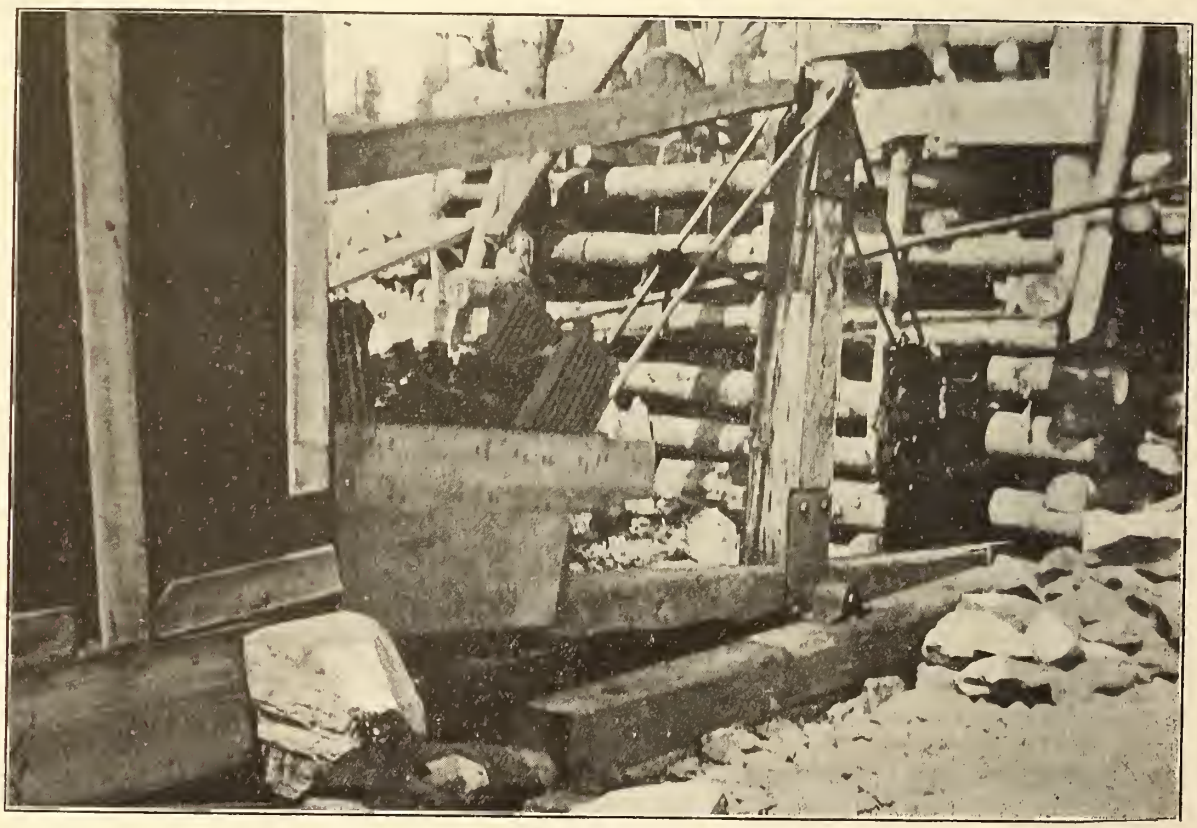
*Abstraet of paper read before the Mining Soeiety of Nova Seotia.

tions and the other precipitating solutions, then pay-shoots would be formed along the line of their intersection. The extent, width, and richness of these would be dependent upon the relative length and width of the fissure through which the gold was passing which was connected with the precipitating fissure, and upon the respective volumes, strength of flow and richness of the solutions passing from one into the other.

A small fissure, less than half an inch in width, may at its intersection with a bedded vein give hundreds of ounces of gold in a small space on the bedded vein near the intersection. As an illustration we may mention the Ross vein in the Holman mine which at its intersection with a half-inch fissure yielded very many ounces of coarse gold, while elsewhere in the workings this vein has yielded practically no pay-ore until very recently at its intersection with another fissure where I am told by Mr. Holman that Mr. Ross, who is now at the mine, reports that it contains some fine gold. This vein carries a considerable percentage of metallic sulphides, much intermingled slate, and other precipitants of gold wherever it has been exposed, but except as noted, has yielded no paying quantities of gold. The small fissure (angular) intersecting it where the gold was taken remained unnoticed for nearly a year until discovered by me, and its probable influence on the vein pointed out.

During the years of erosion and the action of atmospheric and aqueous agencies upon the rocks of the Meguma series, it is very certain that some gold had been dissolved, carried down through crevices, joint-planes, and open fissures, and finally deposited on various bedded veins beneath, forming small pockets or bonanzas of gold.





Cornish Pump at a Nova Scotian Camp.

There are probably several instances known in Nova Scotia where pay-shoots along bedded veins, dipping more or less steeply, have been followed over 1,000 feet down on the incline. These pay-shoots often dip at an angle one way or the other along the vein, and this angle of dip of the pay-shoot has often been between 30 deg. and 45 deg. It may be argued that these instances are seeming exceptions to my assertions, but I am inclined to believe that the bedded veins were not the trunk channels of the gold-bearing solutions, for if they had been we would expect the pay-shoots to be more nearly vertical. The more reasonable conclusion to me seems to be that gold-bearing solutions entered through very narrow fissures, extending to great depths and in contact with the bedded veins for a very considerable distance along the line of dip of the existing pay-shoots. The gold was precipitated in the bedded veins near the point of entrance to them and along the line of the fissure through which they entered. Failure to discover such fissures is merely negative evidence, for like the angular intersecting the Ross vein, they have probably never been looked for, and it is possible that at the present time all trace of them may have been obliterated by subsequently exerted pressure.

As far as my studies have gone in connection with the gold districts visited by me in the Province, the conclusions reached point to the fact that in those districts characterized by well developed anticlinal folds (and some of them by domes as well) the bulk of the gold deposition is directly traceable to the influence of fissure veins, through which the gold was originally brought in solution. At places in the quarzites where I found the veins carrying pay-values in gold, there was in every instance strong evidence to prove that the gold was brought in through a neighbouring fissure; and furthermore places shown me where very rich ore was said to have been taken in the past were all near fissure veins. In these instances, at distances from the fissures where pay-ore had ceased to exist, the vein contents were otherwise identical, save in gold value, and in every instance minerals capable of precipitating gold were present.

Instances sometimes may exist where a fissure comes up to a bedded vein, turns and follows along it for a greater or lesser distance, finally turning again and passing upward. In such a case a pay-shoot would probably be formed along the vein between the point of entrance and the point of departure of the fissure vein, and until sufficient mining had been done to ascertain the truth of the matter it might appear that such a vein was a seeming exception to my conclusions.

It seems evident to me that too little work has been done in developing the various fissure veins, especially the small but nevertheless true fissure vems locally called "angulars" in Nova Scotia. It may be well to explain that the term angular vein as used in Nova Scotia is synonymous with the term "fissure vein" as used by western miners, while western miners generally use the word "angular" to designate any small, generally not extensive, lateral branch, stringer, or feeder of a fissure vein.

It would be my preference in developing a mine in Nova Scotia to sink the shaft at the intersection of a fissure vein with a bedded vein, preferably, of course, at such an intersection as is known to carry pay-value in gold. Where possible the shaft should be carried down on an incline coinciding with the dip of the intersection of the two veins. In such a case the hanging-wall of the fissure will serve as the hanging-wall of the shaft, while that of the bedded vein may be in many instances made to serve as what might be termed

Montagu—Veteran Miner standing behind remains of stamp battery foundations.

the "hanging side wall" of the shaft, but in some cases the angle of dip might necessitate doing otherwise. At various levels reached, drifts can be run along the fissure vein to its intersection with other bedded veins, either known or supposed to exist, and pay-shoots located at such intersections can be stoped up on. Again, where, as is very often the case, parallel fissure veins are known to exist nearby, a drift can be run on the bedded veins at different levels to the intersection with such fissure and pay-shoots stoped up on, etc.

We may say that as a general rule the nearer to the horizontal a bedded vein runs where cut by a fissure vein, the coarser and more nuggety any gold found will be.

Where a bedded vein dips at an angle from the horizontal, some coarse gold will be deposited at the intersection, while much finer gold will be found scattered down the bedded vein to a greater or lesser distance, according to whether its dip is slight or extreme.

Some fissures will give good deposits of gold at their intersection with each of several superimposed bedded veins, while in other instances deposits will be found only at a few of such intersections and intervening ones may be unprofitable to work.

Although there is probably a future time coming when the low-grade slates, conglomerates, and quartz veins will be worked at a profit, I will not dwell on their possibilities in this paper.

In concluding, I wish first to express my admiration of the very complete, accurate, and valuable work done by Mr. E. R. Faribault in mapping the various mining districts, veins, and geological formations of Nova Scotia. The mining industry of the province owes very much indeed to his genius and indefatigable work. Finally, I wish to put myself strongly on record as not being in accord with the conclusions of an eminent mining expert and geologist who was once paid a very liberal sum for his report regarding the future possibilities of extensive deep-mining in Nova Scotia. On the contrary, I believe that the province has a great future before it, and that with ample capital and intelligent development of its mines, Nova Scotia will take its right place among the great mining camps of the world.

Sampling of High Grade Cobalt Silver Ores.

[Editor's Note.—The following article was not available for our last issue. It supplements fully the very brief description then given. Our readers are referred to the last issue for illustrations of the equipment. Only the flow-sheet is here reproduced. The preliminary notes touching the history of the enterprise are most interesting.]

In 1907 Messrs. Campbell and Deyell formed a partnership as mining engineers, and in April of that year took over the business of Mr. C. M. Tilkie, assayer, of Cobalt, operating it on a small scale in conjunction with the practice of engineering. It soon became evident from the trend of events that a sampling plant was positively required in Cobalt; but certain investigations made had resulted in the conclusion that it would be impossible for a custom sampler to obtain sufficiently accurate results from this ore. The result of experiments in the small laboratory of Messrs. Campbell & Deyell encouraged them in attacking the problem, with the result that in November, 1909, the present company was organized with the old assay and sampling business as a nucleus, and construction on the present sampler commenced.

In June, 1910, the first lot of ore was sampled and after a few weeks of experimenting it was demonstrated beyond question that it was practicable to check on repeated valutions of this ore. It must be understood that the hand methods used to that date did not give sufficient moral security to the interested parties and that the two smelters who had mechanical samplers did not attempt to make more than one valuation of a car. This allowed of no check. The present plant is almost entirely mechanical. The points at which the ore is touched by the workmen being subject to careful supervision by representatives. From the time the ore is crushed till four separate and independent samples of the car are obtained, no human being has access to the ore.

The capacity of the plant is about 30 tons per day. This, of course, varies considerably above and below, according to the nature of the ore which is either coarse or fine, dry or wet, hard or soft, free from or full of arsenides, and with varying quantities of metallic silver; thirty tons of ore yielding on occasions as much as two tons of metallic silver from the ball mill screens.

The figures to show the amount of ore that has been sampled are not to hand; but it suffices to say that the machinery has been working day and night ever since the plant was first turned over, except, of course, the usual stoppages for repairs. The patronage of the larger mines has been secured; but, unfortunately, a few of the smaller ones are tied up with contracts with smelters and in other ways prevented from taking advantage of the sampler. It is confidently expected that these few will be taken into the fold in the near future.

In the following article the writer has not touched on the storage of ore, for which there is ample capacity, nor the grading of ores, which has proved to be an important branch of the business, nor the marketing of the ore and bullion: these are lengthy subjects and can be dealt with at a future date if found of sufficient interest.

The following are a few of the reasons why there should be a sampler in Cobalt:

The mines are assured of a neutral and disinterested valution of their product.

The machines give an automatic sampling which, to the greatest possible extent, eliminates the personal equation.

The ore is marketed at the point of production and its contents and value known almost at the mine's mouth. In this way the most advantageous market may be chosen.

Mines having different grades of ore may sample each lot independently and blend them to make a desirable product for the smelters.

The smelter having its representative at the plant may, at the discretion of the mines, determine the

tenor of the various lots of ore and so bid intelligently.

The mine may store the ore, knowing its exact value and contents, and await a desirable market.

Certificates of sampling and valuation may be cashed at the local banks and the value in the raw product realized a few days after it is mined.

Four independent and separate samplings are made on each lot of ore, the reasonable concurrence of the assays on which, put the accuracy of the sampling beyond question.

Custom Ore Sampler—Cobalt.

The ore is delivered to the plant, from the mine, in railroad cars at the mill siding, or else in wagons. It is contained in jute or canvas sacks, each of which weighs, when full, approximately 100 pounds. The bags after being loaded on trucks are trammed into the mill, being weighed at the door on a Fairbanks type registering scale. The tram and ore sacks are subsequently weighed and this tare deducted, and the net green or receiving weight obtained. The ore is either placed in locked bins, or if to be sampled immediately, is elevated (electric elevator), still in bags, to the second or crusher floor. Here the bags are opened and the ore shovelled over a 1-inch grizzly, the oversize going to a 10-inch x 16-inch Buchanan crusher, which reduces it to 1½-inch ring.

The discharges from both crusher and grizzly pass to a cylindrical steel tank with conical bottom, and is thence discharged automatically to the ball mill by an adaptation of the Challenge feed. The ball mill reduces the 1½-inch product continuously and passes it over a spiral screen (8 mesh), thereby discharging the "throughs" into a steel hopper-bottom car and returning the oversize to be reground. Necessarily each lot of ore has to be crushed and sampled separately, and requires a complete clean-up of the mill and the machinery after each lot has passed.

After the ball mill receives the last portions of ore from the crusher tank, the presence of metallics becomes evident from the nature of the ball mill discharges. When it is adjudged that the metallics have been freed from the brittle ore and the mill is discharging a product composed mostly of pellets of silver, a section of the screen is removed allowing the metallics to be discharged in their unreduced form, into a suitable receptacle. These metallics are, at the discretion of the mining company, either bagged, weighed, and shipped to the smelter; or else they are taken to the bullion department and are there melted and cast into ingots. Samples are taken by drilling the ingots. It is usual to ship the bullion by express to the London or United States markets.

To return to the No. 8-mesh product that has been discharged from the ball mill into hopper bottom cars: this is occasionally held in reserve in a steel hopper tank until required for further treatment; rarely it is bagged; usually the car is trammed, directly it is full, to the elevator, elevated to the top of the mill, and there discharged into the sampler feed-tank.

From this point the ore is treated entirely by machines until four separate samples, of about 15-lb. each, are obtained.

The sampler tank discharges its burden into a steel pipe fitted on the inside with a spiral band of steel. This spiral conveyor is rotated by a chain drive, the ore having the combined motion of advancing in the pipe and being tumbled over. This last motion, which gives a mixing action, while not equalizing the whole tenor on the ore passing through, cuts out the sharp lines of difference and enables the sampling machines following to have a uniform product discharged to them during each of their revolutions.

From the spiral the stream of ore is fed by a spout to the quartering machine, which in each of its revolutions takes four equal sections of the ore stream. Each of these quarters is separatedly led by a pipe to a shaking plate, which equalizes the intermittent discharges and delivers a constant stream to the No. A Vezin sampler, which takes a one-tenth cut from the stream (2 1/20 cuts per revolution). The reject falls directly by a pipe to the reject bin. The sample (1,500 pounds) is taken by a second shaking plate and thence to No. B Vezin sampler, which, as before, takes a one-tenth cut. The second reject is also led to the reject bin; and the sample (150 pounds) caught in a sealed sample safe. At the completion of the run all the machines are brushed down and the sample taken to No. C Duplicate Vezin sampler. Here a shaking plate delivers a stream of ore to two double revolving vanes that extract, each, one-tenth sample (15 pounds) depositing each into a separate receptacle and the reject into a third. One sample is boxed, sealed, and stored as a reserve; the other is taken to the finishing room; the reject goes to the bagging bin, or is held over until the next shipment from this particular mine, as are also the mill sweepings and the rejects from the finishing room.

From the bagging bin the ore is drawn off into canvas bags, which are tied, weighed, and shipped to the smelter.

Up to this point the fine product from the ball mill has been automatically mixed, quartered, and each of the quarters independently sampled by machines until eight samples of the lot (two from each quarter) are obtained.

To follow the samples further: on reaching the finishing room the sample is weighed and dried in an electric oven for six hours at a temperature of 100 deg. C.; the moisture is thus incidentally ascertained. The dried product is sereened through 100-mesh and the oversize ground in a Braun disc pulverizer to pass the same mesh. It is at this point that the metallic silver in the ore is again in evidence. The small pellets that pass through the ball mill screen are flattened out, or are rolled into spheres by the discs These metallics, No. 2, are disced until clean as required, or are freed from impurities on the buckboard; the product from all operations either passing through the 100-mesh or being held on it as clean metallics. The metallics are mixed by coning on glass, divided into the requisite number of packets, and sealed. The fines are placed in an Abbe pebble mill, from which the pebbles have been removed, and the jar is rotated slowly for half an hour. After mixing, the fines are carefully removed from the jar, placed on the glass table, flattened out with a spatula and sections taken, packeted, and sealed for each of the parties interested.

In this way, the ore after passing the ball mill screens is divided into four equal portions, each quarter after treatment resulting in a sample each of fines, and metallics. The combined assay values of these two products give one valuation on the ball mill fines. The mean of the results is considered to be a fair valuation of this product. The maximum allowable difference between any of the four valuations is one per cent. Just recently several improvements have made, and it is hoped to reduce this extreme variation limit to about one-quarter per cent. of the total assay value. The mean of the four valuations, of course, reduces

ıe probable variation from the actual value of ore ›t to about one-quarter per cent.

In estimating the total value of the car of ore samp-›d, the amount in ounces per ton of the ball mill fines ; multiplied by the exact tonnage of same, giving the ›tal ounces. The total number of the fine ounces ob-ained from the ball mill metallics is added to this gure, and the result multiplied by the present market rice of silver, giving as a net result the prevent value f the shipment.

Silver Lead and Zinc Deposits of Slocan

Mr. O. E. LeRoy, of the Geological Survey of Can-da, who has during two or three years last past close-y studied the geology and mineralogy of the Slocan district, delivered an address on this subject before the neeting of the Western Branch of the Canadian Min-ng Institute, held at New Denver, Slocan Lake, B.C., ›n September 13. He entitled his contribution to the ›roceedings, "Notes on the Silver-lead and Zinc De-›osits Occurring in the Slocan Slates and Associated Granites." He said:

"The area now under consideration lies between Slocan and Kootenay Lakes, including Four-mile ba-sin to the south, and Whitewater to the north.

"The rocks consist of the Slocan series, comprising interbedded slates, quartzites, and sandstones intruded by certain phases of the Nelson granites, in the form of batholiths, bosses, dikes, and sills, with some later intrusions of basic dikes.

"The vein fissures cross the strike of the formation as a rule, or in cases strike with the formation and cut the dip of the rocks at varying angles. They vary in length from a few hundred to 2,000 feet or more, with widths ranging up to 150 feet. The strike is usually east or west of north, though in some instances it is east and west. The dip varies from 20 deg. to vertical. The fissures terminate in different ways, the most common being the fraying or feathering out on a sharp turn in which the vein peters out along the strike of the formation. In the granite the fissures fol-low the most prominent lines of jointing. The ore-bodies range up to 400 feet or more in length. and up to 40 feet in width, with depths of several hundreds of feet. They are composite and consist of a series of lenses of ore—galena or zincblende — either pure or mixed, lying in lines or "en echelon." As one lens of galena peters out another commences a short dis-tance from it. The paystreak as a rule favours the hanging wall.

"The ores are popularly classified as wet and dry. Wet ores consist essentially of galena with a gangue of siderite; dry ones of silver-bearing minerals usually low in lead, with quartz gangue.

The chief metallic minerals are galena, zinc blende, and grey copper (freibergite), with minor amounts of pyrite, chalcopyrite, ruby silver, argentite, and native silver. In the oxidized zinc, sulphate of lead occurs occasionally, and more rarely linarite or sulphate of lead and copper. The gangue minerals are siderite, quartz, and calcite.

"In the normal type, siderite is first in deposition, followed in turn by zinc blende, galena, and grey cop-per; with yellow copper, pyrite, and quartz toward the closing period. The rule, however, has many ex-ceptions, and the method of deposition is very compli-cated. The value varies from 7 to 75 per cent. lead, and 20 to 200 oz. silver per ton. Gold occurs in many of the ores—from $1 to $7 per ton.

"The developments of the last year are very en-couraging and give strong hopes that the ores occur at far greater depths than has hitherto been considered probable. While the depth at which pay-ore will be found will vary in different parts of the area, encour-agement is taken from the healthy appearance of the veins in the best-developed mines.

"Many of the properties now lying idle, and with no ore reserves, offer favourable blocks of ground for judicious prospecting with which, no doubt, some of them would be found capable of being made produc-tive. Owners of idle properties should be willing to accept a fair sum for their holdings, or to offer liberal conditions for leasing, bonding, or purchase, in order to encourage the expenditure of the capital requisite for the development of such properties, for they would thereby add to the prosperity of the community and impart to the life of the district a healthier tone than has characterized it of late years."

(Note.—Fuller particulars of the Slocan district are contained in Mr. LeRoy's annual reports, printed in the "Summary Report of the Geological Survey for 1909 (pp. 131-133), and 1910 (pp. 123-128," respec-tively).

Lucky Jim Zinc Mine, Slocan, B.C.

(Notes by A. J. Becker, Superintendent.))

The zinc deposits of the Lucky Jim mine occur as a replacement of the lime by a zinc solution.

The ore occurs in a lime dike, which traverses the slates in a direction E. 6½ deg. S., with a dip of 45 deg. S. The slates of the foot wall are very silicious, badly mixed with hard blue lime and iron sulphides. The slates forming the hanging wall are the ordinary Slocan slates. This lime dike varies in thickness from 10 to 200 feet, and the orebodies depend largely on the thickness of the lime dike. The lime dike is frac-tured by fissures taking the usual Slocan course, namely, northeast by southwest, and where these frac-tures are found cutting the lime the deposits of zinc occur. The fractures sometimes extend through the slates, but so far we have failed to find any zinc ore outside the lime dike, although lead ore has been found in these fractures outside the lime dike and in the slates.

So far we have two known orebodies, about 500 feet apart. On the surface of one there is a large deposit of ore, this forming quite a "glory-hole" and extend-ing down to our lower explored level, but decreasing in size owing to the lime dike lessening in thickness, with the ore, however, extending from the foot to the hanging wall slates. The second orebody is 500 feet east of the first orebody; near the surface this showed ore from the slate on the foot to that on the hanging wall, but the dike here showed reverse conditions to that in which the other orebody occurs, for its small-est part is at the surface while it gradually increases in thickness until, on the No. 4 level, it is 180 feet wide. Now this fracture near the surface, and as far down

as No. 4 level, is accompanied by lesser fractures, and these are sometimes filled with paying ore. On the No. 5 level these smaller fractures consolidated into one huge deposit of zinc ore, in places mixed with lead ore, all the lime between the main fracture and the lesser ones having been replaced by zinc.

It is noteworthy that the ore does not always occur in the fractures, but sometimes on either side of the fractures, as a replacement, while the fractures themselves are barren.

From my observation thus far, I am positive these zinc deposits depend upon the depth of the lime dike, and since the lime dike is cut by a deep canyon much lower than our present workings, there appears to me to be a good future for the Lucky Jim mine.

Development.—The mine has been developed by 8 adit tunnels. In the No. 4 (Geo. Hughes tunnel), a winze was sunk 108 feet on the dip of the vein; much of the zinc ore shipped by Mr. Hughes was taken out of stopes opened from this winze. No. 5, which was started from a point 200 feet vertically below No. 4, reached the first orebody at 360 feet from the portal of the adit. This orebody is here 22 feet wide. At 425 feet farther on the second orebody was entered; this proved to be 91 feet in width. In the middle of it there occurs about ten feet of ore badly mixed with iron, and then about six feet of silver-lead ore; after that the ore is all zinc. The total length of No. 5 is between 900 and 1,000 feet. An aerial tramway was erected from the portal of No. 5 down to the Kaslo & Slocan Railway track, alongside which ore bunkers were built, but both tramway and bunkers were destroyed by fire last year, just before they were fully completed.

No. 6 adit was started at an elevation of 27 feet above the railway track. It is now in about 925 feet. We expect to reach the first lime dike within 100 feet from the present face, and afterwards to have to drive through about 75 feet of lime to reach the ore.

Progress in Coal Prospecting

J. A. Wentz, Charlton, Ia.

There are four commonly known methods of prospecting coal lands, which show the same number of successive steps in the development of the art of obtaining exact knowledge as to the commercial value of a given formation. In order of general value they are as follows:

First, sinking of shafts or driving of slopes on the coal vein.

Second, drilling test holes with the churn or percussive drill.

Third, drilling core holes with chilled shot or saw-tooth bits.

Fourth, drilling with the diamond core drill, using the double-tube core barrel.

The first method, which consists in exploring the vein by shafts or other workings, is necessarily slow and prohibitive in cost. The second is cheap and rapid, but the records obtained thereby are naturally unreliable. The samples taken from holes drilled by this method consist of chopped-up particles representing the contents of the hole, the various strata of which are necessarily more or less intermingled, so that determination of the condition of the coal as to purity, and of the character of the overlying and underlying strata, is mere guess work. The third method, that of drilling with chilled shot, or saw-tooth bits, is an improvement over the second, but leaves much to be desired in the matter of drilling speed and condition of the core. The apparatus does not lend itself to the use of devices by which the core is extracted carefully, and does not operate with the precision and smoothness required to prevent the core from being broken up by vibration.

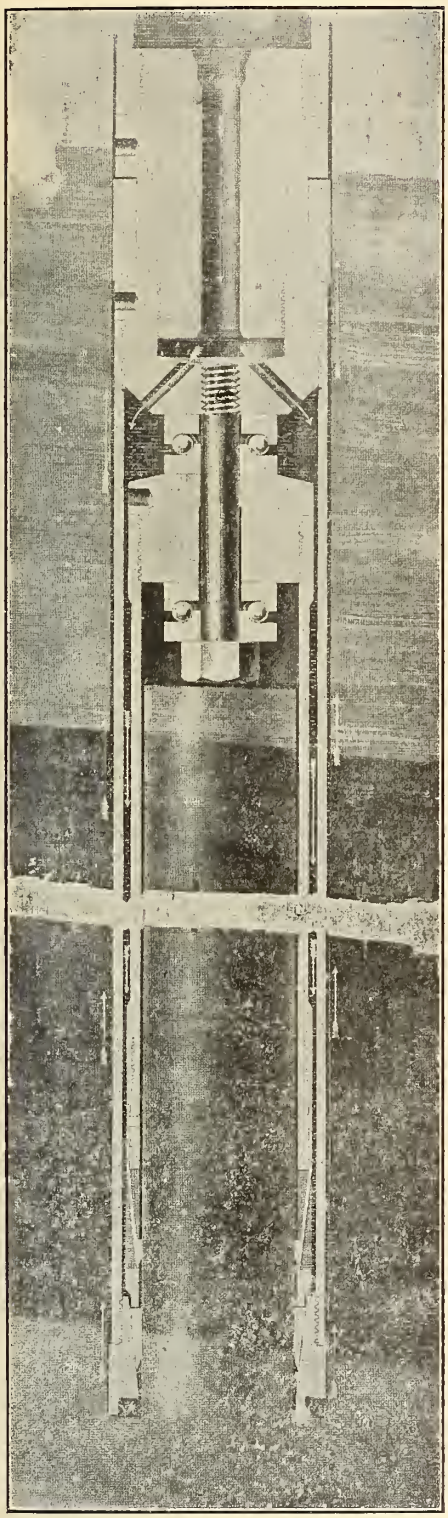
In order to secure even half-way results with machines of this type, it is necessary to use tools taking out a very large core from four to six inches in diameter. This involves a rate of progress and a cost for labour, which increases the price per foot of drilling to an unprofitable degree.

The necessity for obtaining the most perfect records possible is apparent, when it is remembered that large amounts of capital must be expended in the purchase of lands, building of railroads, installation of mechanical equipment, driving of workings, and building of houses, before a coal property can be put on an operating or dividend-paying basis.

It is a fact, accepted almost universally by mining engineers, that the highest development obtained in this art in the diamond core drill, including the double-tube core barrel, which is shown in operation in the accompanying cut. The principle on which this apparatus works is as follows:

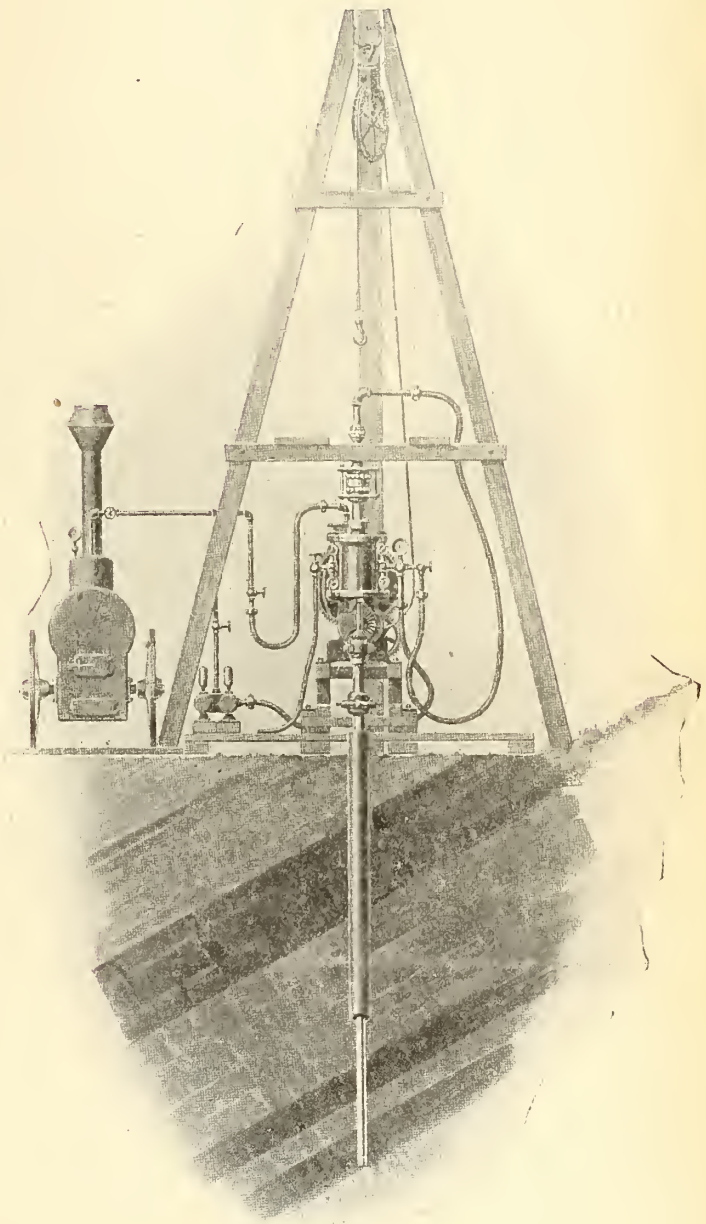
The drilling crown or bit is faced with black diamonds or carbon. This bit is placed at the end of a tube or core barrel, which is of peculiar construction. As implied in the name already mentioned, this core barrel consists of two tubes, an inner and an outer member, the inner one being suspended on especially designed ball-bearings, to make it free of the rotation of the outer tube. The outer tube is made to fill closely the hole and to rotate without vibration. Between the inner and outer tubes is a space through which water is forced, which emerges under the bit, carrying away the cuttings. Close to the bit is placed an automatic device which grasps the core, bringing it to the surface, when the core barrel is lifted.

The core barrel is connected to the drill on the surface by the required number of drill rods, made of hollow steel tubing, in exact ten-foot lengths, by means of which the depth of the hole at any given time is accurately measured. The bit, core barrel, and rods are rotated by means of a suitable engine, and are fed downward by hydraulic pressure regulated by finely graduated valves. The hoisting and lowering of the rod is accomplished by means of a derrick, or tripod, carrying a sheave wheel and a rope, which is wound upon the drum forming a part of the drilling machine. The entire apparatus is designed in strict accordance



Double Tube Core Barrel Passing Through a Coal vein. The arrows indicate the course of the wash water.

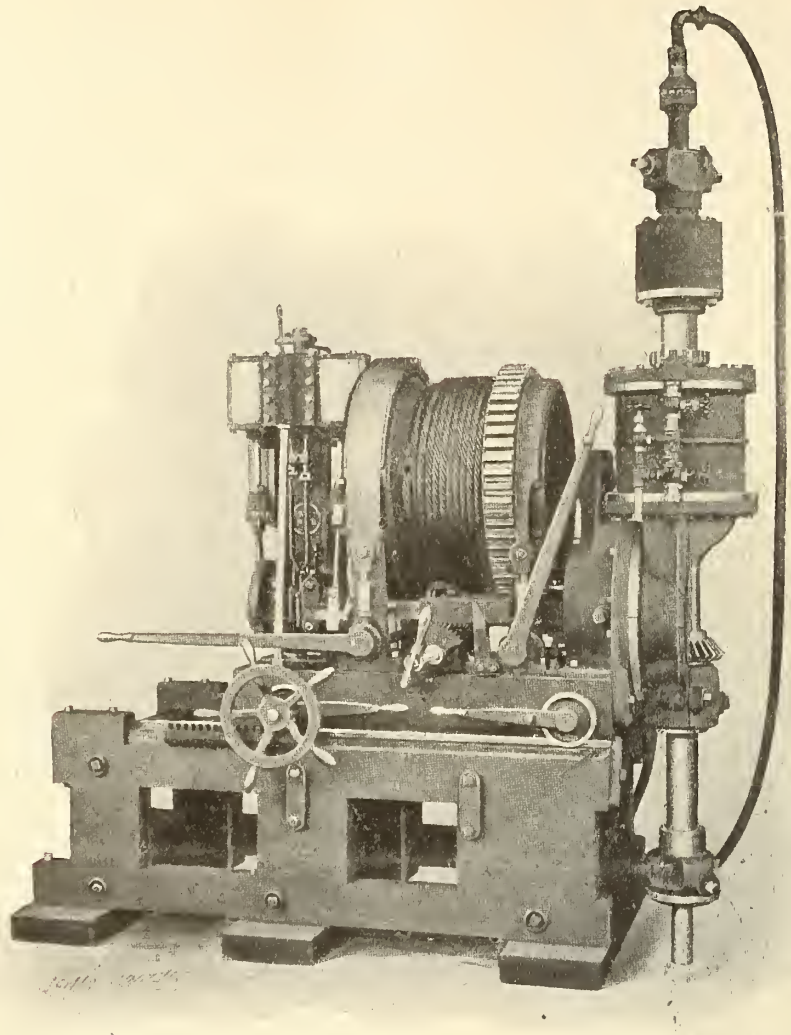
th engineering principles, and every detail of materials and construction in these machines receives the reful attention of the manufacturers. "Built like watch" was the criticism of a recent purchaser of e of these drills. The cores are two inches in diameter, a dimension fixed upon after extensive experience. The cores extracted, even in friable formations, e practically complete, showing only a minute loss



Arrangement of typical Diamond Drill Outfit.

from abrasion, and are a perfect record of the formation existing at the point drilled. They are placed in suitable cases for preservation. Vertical sections of the core may be taken for analysis, as required, the remaining portions being preserved.

The method described is equally applicable to prospecting for any other mineral, and is especially desirable when cores are liable to be broken or ground up by ordinary drilling. In addition to securing reliable records, diamond drills are much more rapid, than any other coring drill, owing to the small diameter of the hole bored, and to the readiness with which the diamond bit penetrates any strata encountered.



Diamond Prospecting Core Drill. Single cylinder hydraulic feed.

While the writer has used various types of diamond drills, as well as other core drilling machinery, most of his experience has been with those manufactured by the Sullivan Machinery Company, of Chicago, and it is to this apparatus that reference is made in the above article.

The Department of Mines in Nova Scotia owns and operates several diamond drills and also some shot drills of the Davis Calyx pattern.

These drills are leased to mining companies, principally coal mining concerns, and the results as to progress and cost are very carefully recorded by the government officials; so that a definite comparison of the work and cost of operation of these two types of machines is available. Such a comparison is very interesting, as it is seldom that the two patterns of pros pecting drills are used in the same formation.

The following table is made up from the records o the Department of Mines for several years past, an throws an interesting side light on the relative propo tion to the whole cost of the cost for diamonds, an the cost for shot. The writer has only figured out th cost of labour and management for one year, 1909 in this year, this item for the diamond drills average 58 cents per foot, and $1.17 for the shot drills.

Table 2 appeared recently in the Engineering an Mining Journal, with the exception of the last co umn, which shows a hole 1,217 feet deep, bored by th diamond drill.

Table 1.

	1907	1908	1909	1910	3 yea
Footage all drills	6273	7905	5576	5222	6234
Footage by diamond drills		2962	3378	4498	....
Footage by Calyx drills		3412	2198	724	
Cost foot for all borings	1.23	1.06	1.405	.99	1.05
Cost foot diamond drills	.73	.845	.59	.93	.85
Cost foot Calyx drills	1.71	1.34	2.166	1.44	1.64
Carbon cost per foot	.029	.077	.037	0.67	
Cost shot per foot Calyx drill	.47	.056	.055	.02	

In the year 1910, the footage on which diamond drilling was based, represented 6/7 of the total work done and the footage on which the shot drilling wa based represented the other 1/7.

Comparison of Hole Boring Costs.

	1 Diamond	2 Diamond angle of 45 deg.	3 Diamond	4 Calyx Shot	5 Diamond

Prospecting Three Centuries Ago.

(Continued from September 1st issue.)

Mark now the fact that Mr. Plattes was by no means devoid of empirical knowledge. In giving further guidance to the prospector, he commands him to "goe "to the bare Rocks, and there to find out the clifts, "cracks, and cranies: this done, to goe to the toppe: "or till you finde some grasse growing right on the "top of the said Cranies, and then to observe diligent- "ly, the kind of that Grasse, and how it differeth from "other Grasse, ordinarily growing in the same Moun- "taine; not onely in forme, but also in colour, which "colour showeth the greatest difference in the heat of "Summer for the subteraneall Vapours issuing out of "the Orifice of Mines, and differ from those which issue "out of the more solide places in the Mountaines."

The next step is to see if there be any "marcasites" visible. These, it is explained, are usually of divers colours "and seldome good for any thing, yet they are "strong signes of Mineralls within, being themselves "the spume or frothe of the better Mettalls, breathed "forth, even as Drinke breatheth up his Yest or Froth "to the Superficies."

"Marcasites," evidently is a generic name for all metallic sulphides and arsenides, for "these if they "be put in an ordinary fire, they will turne blacke, and "yeeld a smell of Brimstone, Arsnicke, Antimony, or "some other thing, commonly called or knowne by "the name of middle Minerall."

Behind all this quaint vagueness there are glimmerings of practical common sense.

Naturally, Mr. Plattes believed firmly in the divining rod, virgula divina. "The operation with the Virgula "divina is thus to be performed: some observe a set "day and houre with certain words and Ceremonies "at the cutting up of the same, which I have found to "bee little to the purpose." In fact, the excellent Plattes tried the rod successfully in any and all circumstances. He concludes, therefore, the reason of this attraction "to bee of Kin to the Load-stone, "drawing Iron to it by a secret vertue, inbred by na- "ture, and not by any conjuration, as some have fond- "ly imagined."

Should it serve any good purpose, our author declares himself prepared to show more experience of that kind than any man in England.

Tight little England did not mark the limits of Mr. Plattes' ambition. The "new Plantations," New England, Virginia, Bermudas, we are assured, offer high chances to the prospector, chances of "more gaine in "one yeare, than their Tobacco and such trifles would "yeeld in their whole lives.'

Because lead is one of the most common metals found in "these Northerne Countries," Chapter 3 takes up the melting and refining of that metal. Regardless of protests from the careful housewife, the reader is instructed to build a grate fire in the chimney-corner. After filling the improvised grate with "Char-coales "Kindled, in the middest thereof set your melting Pot, "with one pound of Lead-oare, and foure ounces of "filings of Iron mingled together, and so blow to it "strongly with a paire of good hand-bellows." The resulting metal is hammered free of slag, and is then assayed and refined. The first test consisted in roughly cupelling two ounces of the lead on a "peece of good Oake-wood," over a fire "about so strong as "to roast a Pigge." In three-quarters of an hour the silver button is to be expected. This is weighed, and

the number of ounces to the "Tunne of Lead" calculated therefrom. Lead that does not yield eight or ten pounds of silver to the ton, is not worth refining.

To make his cupel, or "Test," the ingenious Plattes secures an iron ring about four inches wide, two deep, and a quarter of an inch thick. This is his mould. Then he calcines mutton-bones and beef bones, crushes them fine, "then with a little beere or water tempers a small "part thereof like pappe" so that it will "remaine "clammish, betwixt powder and paste."

For melting-pots "you may bee at choise whether "you will buy the same at the Gold-smiths, or Potters "in London, which sell Flanders melting Pots, or "make them your selfe."

Chapter 4 proves excellent Plattes to be an expert in the metallurgy of tin. "As for the refining of it, I "am sure it cannot be done by any artifice; for I sup- "pose that I have tryed more experiments about it, "than any 10 men in England. . . . but the more I "tryed the worse I sped." Resorting to the expedient of melting equal parts of gold and silver with the tinne, he found that "all was vaine, for the Tinne poisoned "and consumed some of my rich Mettalls." "Refining," in the terminology of the day, embraced the extraction of "royall mettalls" from base metals. Mr. Plattes, confessing his inability to accomplish this, supplies readers with a way of enriching themselves without running any risk "to damnifie themselves in "any manner of value that is considerable." His hint consists in recommending men of quality to set apart a portion of their leisure for the purpose of prospecting.

As the melting of iron cannot be carried on in the chimney-corner, the reader is told "to learne the prac- "tise thereof in every Country almost where he shall "come." Gold, we are informed, can be extracted out of any iron, but the process is so costly that it "satis- "fieth no man."

Copper ore is to be treated like lead ore, except for the absence of iron filings. Refining, also, is done by cupelling with lead. We are warned that "in the "refining of strange Minerals, as Marcasites, and espe- "cially those which the Minerallists call by the name "of Divells Dirt," the test may become foul. It must then be thrown away.

Silver associated with lead ore is subjected to the same simple process. When the silver ore is strongly mixed with spar and stony substances, it is crushed, washed until "the greatest part of the terestreity and "filth" has disappeared, dried and treated with a liquid amalgam of lead and quicksilver.

For the extraction of gold simple amalgamation in a "little Bucket of Iron" is commended, "Quick-sil- "ver being the most friendly mineral to the royall "mettalls."

The method of purifying gold is set worth in Chapter 9. In this the author deplores the enhanced cost of living.

"Cinabar naturall, Antimony, Auripigment, Arsen- "ick, Talcum, Muscovy glasse, Emery and many other "things" are touched on in Chapter 10.

The subject of the next chapter is "the waies to find "out Pit-coales." Neither in extremely fertile nor in barren ground is the mineral to be sought, but "in "ground that is proane to beare wood and thornes. . . . . of an indifferent fertility." . . "Also the said grounds are proane to bring forth large Cattell, "and well horned." We can thus see the disciples of Plattes scouring the country for long horned kine as a preliminary to opening a coal mine.

Chapter 12, the last, is in part an excursion into th realm of botany. On the second last page, however, given an inventory of the equipment needed by th prospector. Thus it runs: "He will neede nothing bu "two or three Pipkins, two or three Urinalls, an Iro "Picke-Axe well steeled, a spade, and a Crow of Iron "if he will be at the charge thereof."

And with this last quotation we must leave Mr Plattes. His book deserves longer and fuller atten tion than it has been possible to give it. No matte how ludicrous some of his statements seem in the ligh of to-day, his was a courageous soul. Peace be with him and his pipkins!

—J. C. M.

Zinc Investigation Progress Report

On July 20 the secretary of the Western Branch of the Canadian Mining Institute wrote to the Director of Mines, Ottawa, requesting that any available information relative to the progress made in connection with the Zinc Investigation and experiments be sent to him in time for submission to the general meeting of the branch of the Institute, convened for September 13th, at New Denver, B.C. Too late for presentation at the meeting he received from Dr. Haanel a copy of a progress report received by the director from Mr W. R. Ingalls, of New York, consulting engineer in this connection. It has not, however, been deemed advisable to incorporate in Mr. Ingalls' report any details of the special experiments and tests which have been made. Mr. Ingalls' report to the director follows:

"In compliance with your request for a report upon the progress of the Zinc Investigation now being conducted by the Canada Department of Mines, I beg to present the following:

"The general plan of the investigation was fully outlined in my report to you under date of January 28.1911, to which I beg to refer you. Since that time work has been prosecuted, especially in the field of electric smelting, this having been done in the metallurgical laboratory at McGill University, Montreal, under the immediate direction of Dr. Alfred Stansfield. A large number of experiments have been made with several forms of furnaces, certain of which have been of rather elaborate construction, and with a variety of raw material.

"Our early experiments were directed chiefly toward a discovery of the metallurgical conditions that have heretofore prevented a satisfactory condensation of zinc as molten spelter. While I cannot say that these experiments have afforded us a complete explanation of these conditions, they have taught us a good deal, but in spite of the knowledge acquired, we have been so far unable to master the difficulties.

"We have, indeed, produced some small quantities of spelter and in certain experiments have condensed a fairly large proportion as molten metal, but we have not yet been able to do that at will.

"Our experiments have thrown light upon the principles of furnace design and have led us to condemn several types that we have tried. Our work has indicated that in order to achieve any material improvement over the ordinary practice of zinc smelting, it is necessary to abandon certain features of the latter and contemplate continuous charging of the ore and reduction material and discharging the residuum with-

t interfering with the process of distillation. These nditions introduce a multitude of perplexing diffilties that can be worked out only by tedious experientation.

"At the request of the secretary of the Canadian ining Institute, and with your permission, I prented at the meeting of the Institute in Quebec, in arch, 1911, a paper on 'The Problem of Mixed Sulide Ores,' (copy of which I attach to this report) iat concisely summarizes the state of the art in the eatment of such ores and the natural obstacles that lock procedure in certain directions.

"A careful scrutiny of the work on the treatment f such ores that is being done by other metallurgists nd investigators has been maintained, and I have xamined numerous proposals that have been present-d with more or less detail, both through your office nd to me directly, but I have not discovered anything ave one that in my opinion holds out any promise of uccessful adaptation to the conditions existing in Brish Columbia. I am conducting correspondence repecting this, but as to inaugurating experiments upon t, I am disposed to hold them in abeyance pending furher progress in our electric work.

"I regard the electric work as being of particular nterest as an exploration in a virgin field of unknown ossibilities. Doubtless with the same idea a great leal of work in this field is being done by numerous nvestigators in both Europe and America. I have been informed within a few weeks that there are now wo electro-thermic zinc smelteries in operation in Scandinavia, viz.: one at Trollhattan, Sweden, using bout 7,000 h.p., and one in Sarpsborg, Norway, using bout 4,000 h.p. Operations at these works were inaugurated five or six years ago, but according to my nformation the results were for several years commercially unsatisfactory, and it is only recently that it has been claimed to have become possible to make spelter from ore upon an industrial scale. The companies operating these works maintain absolute secrecy respecting them, and I have not been able to learn any details as to their operation.

"Apart from the work in Scandinavia, as to the commercial success of which no information is available, the electric smelting of zinc ore is, in spite of all claims to the contrary, not only still in the experimental stage, but is in the infancy of the experimental stage. Even if the metallurgical difficulties can be overcome, which is possible, I am of the opinion that no one, except perhaps the Scandinavians, is yet in a position to make any reliable estimate of commercial advantage or commercial results in any way. It is, however, well worth while to determine the possibilities and publish the results for the general benefit, unveiling so far as possible the secrecy that is likely to be maintained as to the investigations in this field by private interests, having always in mind, of course, the hope that our work may develop a process that will be commercially applicable to the treatment of the zinc ores of Canada."

(Note.—Mr. Ingalls' paper on "The Problem of Mixed Sulphide Ores," is far too long for reprinting here. Those who have access to files of The Engineering and Mining Journal, of New York, can find it in the issue of that journal of July 29, 1911, pp. 211-213. Members of the Canadian Mining Institute may find it in the C. M. I. Quarterly Bulletin for June, No. 15, pp. 23-30).

BOUNTY ON LEAD MINED IN CANADA.

The following figures, obtained by Mr. E. Jacobs, for submission to the meeting of the Western Branch of the Canadian Mining Institute, held lately, show the amounts paid during several periods to July 1, 1911, and the balance unexpended at that date, of the 2,500,000 originally voted by the Dominion House of Commons for the payment of bounty on lead mined in Canada:

Total expenditure (under first Lead Bounty Act),) during period ended June 30, 1908	$700,390.04
Paid during fiscal year ended March 31, 1909	274,447.50
Paid during fiscal year ended March 31, 1910	343,099.08
Paid during fiscal year ended March 31, 1911	249,370.38
Paid during three months ended June 30, 1911	49,713.32
Total amount paid as bounty on lead	$1,617,020.32
Add amount appropriated for zinc ore reduction experiments	50,000.00
	$1,667,020,32
Balance still available as at July 1, 1911	834,979.68
Total amount voted	$2,500,000.00

Industrial Section

WIRE ROPE.

The manufacture of wire ropes of exceptionally large size and high breaking stress has made such great strides of late years that a brief description of some recent examples in this important branch of manufacture may prove of interest to our readers.

Wire ropes may not loom very large in the mind of the ordinary lay reader, but it is well known to all those who are engaged in operating our mines, lumber camps, engineering, and contracting in all its branches, that wire ropes play a very important part in the successful working of all these industries.

The old-established firm of Thos. & Wm. Smith, Ltd., of Newcastle-on-Tyne, England, has for many years past done a large and increasing business in all classes of wire ropes throughout the Dominion of Canada, and the following particulars of some exceptionally large ropes that it has recently completed will serve to show what results can be obtained from the products of a really live wire rope works.

Our illustration shows the largest warship hitherto launched for the British navy, the Dreadnought cruiser "Princess Royal," recently launched from the Barrow Yard of Messrs. Vickers, Ltd. Owing to the ex-

ceptional length and launching weight of this vessel, Messrs. Vickers naturally went very closely into the question of launching checks, and the contract for these important ropes was finally awarded to Thos. & Wm. Smith, Ltd. The ropes were 8 inches in circumference, having a total length of about 5,000 feet, and whereas the British Admiralty specification for this size of rope calls for a breaking stress of 170 long tons, Messrs. Smith were able to give a guarantee of 200 long tons for these ropes. A test piece was cut off each coil and sent to a public testing house, and it is a wonderful testimony to the excellence of the material and manufacture of these ropes that the testing machine was unable to break a single one of the test pieces, although the full stress of 200 long tons was applied in each case for two minutes. A still higher breaking stress was recently obtained by the same firm from a 7¾-inch circumference flexible plough steel wire rope, which they supplied to the War Department for a heavy gun dipping crane at Woolwich Arsenal. This rope was 1,896 feet long, and a test piece submitted to a public testing works broke at a stress of 246 long tons—a truly remarkable result for a rope of this size. A still larger rope was also supplied a short time ago by Messrs. Smith to the Aukland Harbour Board. This rope was 9½ inches circumference, and was tested at a public testing house under Admiralty inspection, breaking at a stress of 348 long tons, which is within two tons of the limit of the largest testing machine in Great Britain. It is true that such large ropes as those we have mentioned have seldom if ever been used in this country up t the present, but the requirements of engineers ar growing more exacting every day, and it is comfor ing to know that whn called upon, up-to-date wir rope manufacturers in the Old Country can still mee any demands that may be made upon them.

Amongst the more important orders for the Dom inion recently fulfilled by Messrs. Smith may be men tioned a large slope rope for one of the most import ant companies in Nova Scotia, which was 20 000 fee long by 1⅛-inch diameter and weighed 22½ long tons and a hauling rope for an aerial cableway in Britis Columbia which was 38,000 feet long by 1-inch dia meter, and weighed 27 long tons.

Westinghouse Officials

At a meeting of the Board of Directors of the Westing house Electric and Manufacturing Company, held in New York on August 1st, the following officers were elected:—

Chairman of the Board of Directors—Robert Mather.

President—Edwin M. Herr.

Vice-Presidents—Loyall A. Osborne, Chas. A. Terry, Harry P. Davis.

Acting Vice-Presidents—Henry D. Shute, George P. Hebard.

Comptroller and Secretary—James C. Bennett.

Treasurer—T. W. Siemon.
Auditor—F. E. Craig.

Mr. E. M. Herr is elected to succeed Mr. Edwin F. tkins, who has been president of the company since ıne, 1910, and who declined re-election.

Mr. Herr has been first vice-president of the company ace 1905. He has announced the appointment of Cal-ert Townley as assistant to the president.

Edwin M. Herr, who was elected president of the Vestinghouse Electric and Manufacturing Company at meeting of the Board of Directors held in New York ugust 1st, has been the first vice-president of this com-any, and in charge of operation of same at East Pitts-urg since June 1, 1905.

Mr. Herr was born in Lancaster, Pa., May 3, 1860. pon completion of a common school course, he was iven the position of telegraph operator on the Kansas acific Railroad, with which company he remained for vo years. He was promoted from the construction ain service to the position of station agent.

In 1881 he entered the Sheffield Scientific School of ale, graduating in the class of 1884, and worked as an pprentice in the shops of the Pennsylvania Railroad ompany at Altoona, Pa., during the two summer vaca-ons.

From 1884 to 1885 he was an apprentice at the West ilwaukee shops of the Chicago, Milwaukee and St. aul Railroad. He then went to the Chicago, Burling-n and Quincy Railroad Company as a draughtsman in he mechanical engineer's office, and afterwards became ssistant engineer of tests, and was promoted from this osition to engineer of tests on this road at Aurora, Ill.

From 1887 to 1889 he was superintendent of telegraphy, and from 1889 to 1890 was division superintendent of this road.

From 1890 to 1892 he was division master mechanic of the Chicago, Milwaukee and St. Paul Railroad at West Milwaukee.

From 1892 to 1894 he was superintendent of the Grant Locomotive Works at Chicago.

From 1895 to 1897 he was superintendent of motive power and machinery of the Chicago and Northwestern Railroad. From June 1, 1897, to September 10, 1898, he held the same position with the Northern Pacific Railroad.

On September 10, 1898, he became assistant general manager of the Westinghouse Air Brake Company at Wilmerding, Pa. He was promoted to the position of general manager on November 1, 1899, which position he held until June 1, 1905, when he was elected first vice-president of the Westinghouse Electric and Manufacturing Company.

Mr. Calvert Townley was for many years connected with the Westinghouse Electric and Manufacturing Company, at first in Pittsburg, and later as manager of its Boston office, and as special representative in New York City. He comes to the company directly from the New York, New Haven and Hartford Railroad Company, where for the past five years he has been closely identified with the electrification of this road.

Mr. Harry P. Davis has been with the Westinghouse Company for twenty years, and for the last few years has held the position of assistant to first vice-president and manager of engineering at the East Pittsburg Works.

SPECIAL CORRESPONDENCE

ONTARIO.

obalt and Gowganda.

Much above the average were the shipments of ore from obalt for the week ending September 22, when thirteen mines nt out 18 cars, of which 11 were high grade. The total eight was 1,181,790 pounds, or 590.89 tons, as compared with 3.67 tons the preceding week. During that week Nipissing nt out bullion worth $22,670, and the Temiskaming sent t 7 bars valued at $3,600. For the week ending September 9th the shipments were slightly heavier than for the week efore. Nineteen cars of ore were despatched by 12 mines, the e totalling 1,200,525 pounds in weight, or 602.26 tons. Of is 10 cars were of high grade, and with the other shipments uring September all above the average, this week's will make eptember the record month for the first nine of this year.

obalt and Gowganda.

Sinking on the main shaft of the Temiskaming has com-enced from the 575-foot level, the object being to attain a epth of 650 feet, where the eighth mine level will be cut. The haft is now down over 600 feet and but a short time will be ecessary to reach the required depth. The new vein at 575 eet, cut 10 feet west of the shaft, is producing some high rade ore.

During the month of August, the Buffalo mill made a much etter recovery than was the case in the preceding month, nd the grade of ore treated was higher than in July. In ugust 144,446.06 ounces of silver, shipped previously, were aid for. Following is the mill report:

Mill run .....hours	592½
Ore milled ....tons	3,093.5
Ounces recovered	94,041
Mill expenses	9,439.76

A shipment of 51,066 pounds of high grade ore was made last week from the Miller Lake-O'Brien at Gowganda, the ore being hauled over the summer road. This operation, ordinarily taking slightly over a week, required three weeks for completion.

During the fiscal year ending August 31, the Temiskaming and Hudson's Bay Mining Company shipped 676.32 tons of ore. The average assay was 1,191.10 ounces to the ton, a total of 805,572.88 ounces of silver. The new mill treated 11,109.6 tons of ore. Manager Young, in his report, says that the ore in sight assures equally good results for the coming year.

Last week gold bullion was shipped from the Gold Pyramid and the American Eagle, in Munro Township, the former sending out 70 ounces, valued at $1,400, and the latter 120 ounces, worth $2,400. Shipments of bullion have previously been made by the Gold Pyramid and the Detroit Syndicate properties.

During the week ending September 30th bullion shipments were made by the Nipissing on two separate days. One consignment was of 53 bars, valued at $28,400, and the other of 59 bars, valued at $30,800, total value $59,200.

At the 75-foot level of the McKinley-Darragh, exploration work in an abandoned working has led to the discovery of a rich vein. About 30 feet of drifting has been done on this ore body and high values are being secured.

This week saw the completion of the new shaft house and hoist house at the Gould Consolidated. Two drills are at work underground and the new shaft, which was commenced during the summer, has reached a depth of over 90 feet. The first station will be cut at 100 feet and the shaft may be continued to the 200-foot level.

Mackenzie and Mann have sent a large force of men into the West Shiningtree district, northwest of Gowganda, to work on their newly acquired claims there, purchased for a large sum from Gosselin, and although little is heard of the section, there is still a steady rush into the new field, and every day reports come out of new rich finds. A gang of 20 men has gone in to work on the Eplett-Caswell property and men are also working on the claims of the Sudbury Syndicate, bought from a man named Thomas, and situated on the shores of Cow Moose Lake. The Canadian Northern is cutting a good road in, and the journey in from the end of the steel is now but a half day's canoe trip.

Porcupine and Swastika.

Extensive exploration work is being done on the property of the Pike Lake Gold Mines, at Swastika, and some good free gold showings have been uncovered. A drill is now down about 50 feet and at 60 or 70 feet it is expected to strike the main vein. Little but surface work and testing has been done so far. The main vein, which is from 4 to 25 feet wide, has been traced for several hundred feet and a hexagonal ore body now being stripped of overburden is over 30 feet wide in places. It is made up of schist and quartz stringers.

Considerable development work is being accomplished on the McAulay-Brydge claims in Bristol township, recently purchased by the Cartwrights, of Cobalt and Porcupine. No. 1 shaft on the western end of the big dyke is now down about 20 feet, and in the shaft there is a 5-foot vein of solid quartz in addition to a smaller vein on the north wall. The other shaft is down the same distance near the eastern end of the claim. A gang of 30 men is employed in prosecuting this work, and a diamond drill is working.

A new vein carrying a spectacular showing of free gold has been opened up on the LaPalme property in Whitney township. The vein averages 6 feet wide and has been uncovered for nearly 200 feet. This is the 23rd vein opened on this property in which free gold has been found.

Within three days, three spectacular strikes were made on the Lucky Cross property at Swastika, and development work is being pushed at as rapid a pace as possible. A number of very promising veins have been opened and the ore bodies are proving to be of great size. These free gold showings were found while sinking, shot after shot bringing out rich samples.

On the south side of the lake a new shaft has been started on the Plenaurum property, and a depth of nearly 20 feet has now been reached. A boiler has been installed and a headframe erected so that when the compressor arrives it may be set in operation and work carried on at full capacity with as little delay as possible. A depth of over 50 feet has been attained in the main shaft.

Last week saw the starting of the plant at the Swastika mine. The outfit includes a 10-drill compressor and boiler, and four large machines are in use underground. The new main shaft has been timbered to 100 feet, and last week the drills started on the raise from the 200-foot level from the old shaft to reach the 100-foot level of the new or main shaft. At the present time, at the 200-foot level, a drill is driving on the main lead and the original values are still being encountered in the vein. A force of 65 men is engaged under Capt. John Reddington, formerly of the Coniagas, and superintendent of the Cobalt Provincial.

A 40-stamp mill is to be erected on the McIntyre, on which property over $250,000 will be expended. Five shafts are to be sunk on this property, and three of them are now well under way. The big 12-drill compressor is runn and work in shafts No. 1 and No. 4 is being pushed at rapid pace. It takes many men to work with 12 drills, a President Freeman, who has just returned to New York af visiting the property, says that from now until the first next year underground work will be prosecuted at the rate 2,000 feet per month.

Four shafts are to be sunk on the West Dome, which n has its camp buildings almost completed. The shot drill now drilling the last hole that will be sunk, and shaft No. where so many lives were lost in July, is being pumped o Work is now going on in three shafts. In all portions of t property tests have been made with the core drill to a dep of 400 feet and the results have been highly pleasing to t management.

Last week underground work on the Preston claim of t Preston East Dome was resumed for the first time since t fire, two shafts having recently been pumped out. At the foot level of the other shaft unwatered, 50 feet of cross-c ting and drifting has been accomplished. A new shaft h been started on the Preston vein and the shaft on the E Dome claim is down 30 feet.

Free gold has been found on the claims of the Sociate Min Limited, located in Deloro. In addition to the showings gold in the free state, high assays have been received fr other veins opened up. These claims are owned by a compa of yeung Americans, who have a force of nine men enga in development work.

Excellent progress is being made in the rebuilding of t structures destroyed at the Dome mines. New camp buildin of brick veneer are being erected and large numbers of m are busy in the reconstruction of the power plant, mill, a cyanide plant. Supplies are coming in rapidly on the Dome siding and approximately 300 men are on the payroll. So of the machinery damaged by the fire has been repaired, b considerable new equipment was found necessary.

No. 2 shaft at the Hollinger is now down 100 feet and will be continued as quickly as possible to the 200-foot lev Not until the Pearl Lake extension of the T. & N. O. is co pleted will the heavy machinery be brought in, so that it w be some time in December before development work is ca ried on on the scale contemplated. The sleep camps and se eral cottages are being erected on the Timmins townsite.

High assays have been obtained from drill cores on the Pea Lake property, and a main shaft, 13 by 5 feet, is to be sun in a spot calculated to tap several large ore bodies. This sha will go to 400 feet before any cross-cutting is done, and wi be about 350 feet north of a line connecting B shaft and sha No. 2.

There is another rush in progress to McArthur townshi where rich finds were made earlier in the summer. This tim the rush has been caused by the free gold discoveries on Mc rison's and on Hull's claims. Some very rich samples hav been brought out, and these properties are being developed o a fairly large scale.

A deal has just gone through in Montreal by which th Crown Chartered has taken over the Davidson property o which it had held an option for several weeks past. Th Davidson claims, 5 in number, adjoin the Crown Charter and are located in North Tisdale. At a depth of 70 feet en couraging values are being encountered, and this addition o 200 acres should prove a valuable acquisition.

Cobalt Ore Shipments.

Following are the ore shipments from Cobalt for the wee ending September 22nd, in pounds:

La Rose	238,480
Nipissing	151,090
Coniagas	123,150
Cobalt Townsite	100,520

McKinley-Darragh	64,250
Kerr Lake	60,870
Right of Way	56,980
Trethewey	56,980
Crown Reserve	50,800
Temiskaming	40,320
	1,181,790

Following are the shipments for the week ending September 29th, in pounds:

La Rose	278,780
Cobalt Lake	183,450
McKinley-Darragh	120,600
Drummond	120,000
Cobalt Townsite	65,100
Nipissing	63,980
Chambers-Ferland	63,900
Hudson Bay	53,000
Right of Way	61,500
Kerr Lake	60,930
Beaver	60,785
Coniagas	58,500
	1,200,525

BRITISH COLUMBIA.

Mining is progressive in several districts of British Columbia, notably on Vancouver Island and in Nicola Valley, of the coal mining parts of the province; and in Slocan, Sheep Creek, Hedley, and Coast camps, among the metalliferous mines. The Hedley Gold Mining Company has declared another five per cent. dividend on its issued capital of $1,200,000, this being the third distribution of $60,000 this year by this company. In Rossland camp, the War Eagle mine is continuing to produce much ore of good grade, while others of the Consolidated Company's mines in that locality are also doing well. The Le Roi No. 2 is regularly maintaining its normal output, with results that admit of the occasional payment of a dividend.

There does not appear to be any immediate prospect of a settlement of the strike of the coal-mine employees in the Crow's Nest Pass district. It is stated that the companies concerned are endeavoring to obtain men to work in the mines, but the only colliery reported to be producing and shipping coal in the district is that of the Corbin Coal and Coke Company.

Slocan.—The construction of the railway spur from the Canadian Pacific Railway at Three Forks to Bear Lake, on the divide between Slocan and Ainsworth mining divisions, is being pushed on while the weather continues favourable for outdoor work. Meanwhile preparations are being made at both the Lucky Jim zinc mine and the Rambler-Cariboo silver-lead mine to ship ore in considerable quantity when the new railway shall be completed.

Mines in the Cody section of Slocan district are expected ere long to again ship ore. In the Noble Five mine, both silver-lead ore of good grade and silver-zinc ore containiug a high percentage of zinc have been developed during recent months. There is also a probability of the Surprise mine again shipping ore soon, for the long raise from the 1,100-foot level up 850 feet to the bottom of the old workings will probably be completed before winter shall set in. Development work is being done on both the Reco and Sunset mines, also in the vicinity of Cody Creek, while near Sandon the Ruth-Hope and Richmond-Eureka groups are being operated.

Similkameen.—From a recent number of the Similkameen Star it is learned that the deal for the Voight group of mineral claims, situated on Copper Mountain, near Princeton, is practically complete. Representatives of the British Columbia Copper Company have been endeavouring to get titles cleared, before undertaking development work. Prospecting shafts are being sunk to bed rock in ground situated at the forks of the Similkameen and Tulameen Rivers, and held under placer mining lease. Work is being done on the Lucky Pair group, in Whipsaw Creek camp, a few miles up the Similkameen from Princeton. Development work is also in progress on mineral claims in several other camps in the district, these including Copper Mountain, Roche River, Fivemile, and Coquihalla Pass.

The Princeton Coal and Land Company is employing fully 100 men at its coal mine at Princeton, and is shipping up to 200 tons of coal per day. Facilities for mining on a larger scale are being provided, and it is stated a screening and dry-cleauing plant is to be put in, so that a thoroughly marketable grade of coal may be produced continuously. A preliminary small shipment of coal has been made from the Columbia Coal and Coke Company's Coalmont mine, situated between Granite Creek and Collins Gulch, about 15 miles up Tulameen River from Princton. Here the adit being driven to cut the coal at the depth of about 1,200 feet on the incline, is in 1,600 feet; it should be in coal when driven 500 feet further. Mr. Geo. L. Fraser, manager of the company, who had been visiting the eastern States in connection with ordering coal-handling plant and machinery, has returned to Coalmont, where the construction and equipment of the tipple and other facilities for the shipment of coal will be energetically proceeded with.

Not much information has lately been received relative to mining operations in the Tulameen district above Otter flat, but it is understood the company organized by Mr. Chas. F. Law, of Vancouver, is prospecting its gold-platinum-bearing gravel deposits, preliminary to taking steps for the recovery of these metals in commercial quantity.

Nicola Valley.—An important development has lately taken place on the property of the Nicola Valley Coal and Coke Company, Middlesboro, Nicola Valley. The company's chief coal-mining operations have heretofore been in what is known as Coal Gully Hill. A few months ago the directors authorized the expenditure of between $90,000 and $100,000 in additional plant, machinery, buildings, and other surface improvements and in further development underground. Included in the programme of progress was diamond-drilling, and a contract was let to the Sullivan Machinery Company to drill about 4,000 feet of holes in various parts of the property. For prospecting underground, the company purchased a small diamond drill. Since then the Sullivan Company has been engaged in drilling on lower ground than that in which the company has been mining, and this work has been done in what had previously been regarded as probably uon-productive ground. The result has amply justified the expenditure, for, first, what was thought to be an extension of No. 4 seam was encountered, size and character of coal being similar to that mined from No. 4; next, a second seam, believed to be an exsion of No. 5, has been passed through by the drill, and now the bore is being deepened with the expectation that No. 1 seam, which lies beliow No. 5, will be found as well. Where the drill passed through No. 5 there was 7 feet of coal in the core, but this is not the right-angle thickness of the seam, for the hole had been drilled diagonally; where mined, though, No. 5 contains 5 feet of good coal. Nos. 4 and 1 are both larger seams where mined in the developed part of the property, so it is to be expected they will also be larger where now found.

The contract time within which the new tipple at Midddlesboro was to be completed expired on October 1st, but the contractors required a short time longer to get it into running order. Nos. 4 and 5 mines have been connected by means of a rock tunnel, so that all coal from No. 4 can now be hauled out through the haulage way of No. 5 mine. The recent additions to plant and machinery include a complete coal-screening tipple with picking conveyors, slack conveyors, and car hauls,

capacity 1,000 tons per 10-hour day; a 50-ton raw coal per hour Stewart coal-washing plant, and storage bins of frame construction with the requisite foundations; a box car loader; and all machinery in tipple and washery necessary to receive, handle, and load out into box cars mine-run coal at the rate of 100 tons per hour. As indicating the progress this company has made in production, the following figures showing yearly output of coal are quoted: In 1908, 25,600 long tons; in 1909, 62,210 tons; in 1910, 141,487 tons. Production figures for the current year are not at present available, but it is known they show a substantial advance over those of last year, while a still greater increase may be looked for now that coal-handling facilities up to 1,000 tons per 10-hour day have been put in.

Howe Sound.—While little information has been published lately concerning the operations of the Britannia Mining and Smelting Company, it is stated by men believed to be well-informed that this year's developments in the company's mines, situated on Britannia Mountain, in the vicinity of Howe Sound, are the most satisfactory yet experienced by the company during the course of several years' persistence in developing its mines and proving the value of the orebodies occurring in them. No particulars have been obtained, but it is understood that ore of higher grade than that mined in earlier years has been found in considerable quantities, and that production has been enlarged accordingly. The further statement is made that the mines are now being worked on a profit-earning basis and the outlook is correspondingly encouraging. No other copper-mining enterprise yet undertaken in the Coast district of British Columbia has been conducted under similar conditions, long decidedly discouraging to those who found the large amount of money that has been expended in extensively exploring this property, so that the news of eventual success will be generally received with much gratification, and the abundant success of the Britannia company be earnestly hoped for.

Vancouver Island.—Efforts have been made to secure capital to work the hydraulic placer-gold mine at the mouth of Sombrio and Lost rivers, on the southern coast of Vancouver Island. This enterprise was undertaken in 1909 and continued in 1910 by a syndicate known as the Sombrio Mining Partnership, which acquired five hydraulic and four creek mining leases. The ground covered by the leases, as described in the last Annual Report of the Minister of Mines, consists of a large deposit of gravel formed at the mouth of the Sombrio River, at which point it is probable the old channel of Lost River also came out, although the latter stream now finds its way into the sea through a new channel, two miles to the eastward, out through the rim-rock of the older channel. is stated that the quantity of gold-bearing gravel availab here is large. Immediately back of this gravel delta the hil rise rapidly. These hills are composed of schists, greenstone conglomerate, sandstones, and shales, with heavy deposits gravel that at one time filled the river valleys, which we evidently gouged out by glacial action. Into these grave beds the present streams have cut deeply, depositing their d tritus—and probably the gold—in the delta comprised with the leases. The water supply is furnished by the Sombrio an Lost Rivers, the former estimated as having a flow of 40 cubic feet a second, and the latter 700 cubic feet; this wate has been brought on to the ground in a flume, under a hea of 200 feet. A good dump for tailings, into the sea, is avai able for all time. It is estimated that the gold content of th gravel is about 15 cents per cubic yard. The partnership ha put in 4,900 feet of steel rivetted pipe, of different sizes—1,40 feet of 24-inch, 1,000 feet each of 22, 20, and 16-inch, and 50 feet of 9-inch; also 300 feet of flume, with suitable head gates, and two 4-inch giants. Mine buildings consist of large cabin, cookhouse, blacksmith shop, office, stable, etc. accommodation having been provided for 20 men. The tota outlay has been about $35,000. The partnership attempted t hydraulic the gravel, but as the deposits were covered by heavy growth of timber and underbrush, these caused unex pected obstacles to the work, which was eventually suspende until such time as additional capital can be obtained to pro vide means for the removal of this forest growth.

Texada Island.—Mines on Texada Island are not now so pro ductive as in several recent years, except in the case of the Marble Bay mine, owned and operated by the Tacoma Stee Company, which has increased its production of gold-copper ore. Much development work has been done during this year in the mines of the Cornell-Copper Queen group, but the output of ore was smaller while this work was being carried out. The Little Billy and other mines on the island are expected yet to become productive, for it is known that in several there are ore-bodies that give promise of proving well worth working if the requisite capital to open them sufficiently shall be obtained. The big iron property, owned by the Puget Sound Iron Company, has not yet been sold, although negotiations looking to its purchase have been carried on. Smelting copper ore, with oil for fuel, in the blast furnace at Van Anda is expected to become practicable on a commercial scale after furnaces shall have been built to meet the special conditions the demonstrations made during recent months have shown to be requisite to successful operations.

GENERAL MINING NEWS.

ONTARIO.

Porcupine, Out.—Camp building at the West Dome is proceeding with rapidity, machinery is being installed, and from now on the management will mine.

Four shafts will be sunk on the property and every effort will be put forth in carrying on the work of development as rapidly as possible. But one more hole will be bored by the shot drill, and in a few days' time work on the No. 1 shaft will be commenced. This shaft, where the terrible loss of life occurred in July, has been filled with water since the catastrophe that resulted in the tying up of operations for so long a period, but it will be pumped out and sinking resumed.

Prospecting operations have been satisfactory, and during the winter all efforts will be confined to underground workings. In all portions of the property tests have been made with the shot drills to a depth of 400 feet.

Toronto, October 6.—With a view to realizing on the Keeley mine, which has been practically idle since the disastrous failure of the Farmers Bank, the liquidator, Mr. G. T. Clarkson, has prepared several plans on which tenders will be called for in the course of a few days.

The first proposition will be in the nature of a bonded lease, an option on the property being offered provisionally on a certain sum of money being paid over and an undertaking given that an adequate sum will be expended yearly in development work, the bank working in as a partner until the whole of the option has been taken up. The other proposition, and the one that finds more favour, is the selling of the mine outright.

Cobalt, October 10.—Thorough prospecting operations on the rethewey have resulted in the opening of another new vein shaft No. 2. This vein is not large, but it carries high alues. It was found in the southeastern corner of the claim. here cut, the vein shows about two inches of smaltite and iver, the latter ruuning in the neighbourhood of 3,000 ounces the ton.

Porcupine.—The shaft on the Rea at Porcupine has nearly ached the 300-foot level.

If values still are found at the depth consistent with those gher up, the shaft will immediately be sunk to 400 feet.

Shaft No. 2, 175 feet west of the main shaft, is down to the 0-foot level, and is connected with the main shaft by a rift along the main wall. The main vein has been uncovered r over 400 feet, and is fairly wide. Trenching is being done ong the west end of a large ridge in an effort to locate more eins.

Porcupine, October 9.—At 55 feet in the shaft the main ein of the Dobie has been cut. At this point the vein is dip- ng to the north and values are exceptionally high. Manager harles Watson says that the values have not been deter- ined by assays. A few feet deeper it is expected that au- her vein will be encountered.

ALBERTA.

Blairmore.—At Blairmore there are upwards of forty men orking at the mines and the daily output of coal is consider- oly over a hundred tons. The management report that they an get all the help required and that every day there are ap- lications for work from experienced miners. The number at ie Blairmore mine of the West Canadian Collieries will be ncreased as soon os sufficient accommodations have been pro- ided.

At Frank there are several miners working and considerable al is being mined. More men will be added in the near fu- re and the daily output will be greatly increased.

At the Davenport Company's mine at Burmis there are forty en working and the daily output of coal at that camp is over ne hundred tons.

The mines at Passburg and Police Flats, which are owned by ie Leitch Collieries, are working full swing. There are at resent 125 men working at these miues and they are shipping etween two hundred and three hundred tons of coal per day.

Lethbridge, Oct. 11.—Every local in District 18, United Mine Vorkers of America, is represented at the miners' conveution ere to-day to consider the strike situation. At the noon ad- ournment nothing definite had been decided on. It is stated hat the men have practically decided to accept the Gordon ward as to wages, and the only thing they are now holding ut for is the recognition of the check-off system, which, in hort, means the recognition of their union. Whether they will tick out for this or not is not known, and the subject forms he main part of the discussion at the convention. President White, of the International Uuion, is present, and, it is be- eved, will have some settlement made before he leaves for ndianapolis.

BRITISH COLUMBIA.

Phoenix, B.C., Oct. 5.—The opening up of the Standard mine t Silverton has resulted in the operation of the Alpha and the nacortes properties which were prospected by the Standard's our tunnels, which traversed the other's property. James Mc- Vaught, of New York, who is the principal owner of the lpha and Anarcortes, has just paid the mine a visit, with the bject of making suitable arrangements with the Standard ompany to permit of his ore being shipped through the Stand- rd's tunnel and over the latter's tramway.

Vancouver.—Nine thousand dollars was the jury's verdict for Peter Collins in the suit against the Britannia Mining & Smelting Company, for the loss of the sight of both eyes in an explosion at the mines. "An employer is not an insurer of his employees," said Mr. Justice Morrison to the jury, "but he must adopt reasonable precautions which will ensure the safety of his employees. You must also remember that au em- ployee is not an inspector of his employer's plant." S. S. Taylor, K.C., appeared for the plaintiff.

The steamer British Empire is here from Prince Rupert with 500 tons of concentrates from the Portland Canal Mining Com- pany's conceutrating plant for the Tacoma smelter. The Bri- tish Empire has been given a contract to carry fortnightly ship- ments of concentrates from the canal to Tacoma and this is the first trip.

UNITED STATES.

Salt Lake City, Utah, Sept. 20.—With but one shift operating the 30-ton mill at the old Ima mine in Idaho, during the past three weeks, 12 tons of tungsten concentrates, worth $400 a ton, or nearly $5,000 for the run, has been turned out and will be shipped to Denver.

The Ima was opened up about 10 years ago. It now has 3,000 feet of development work.

The mill is turning out about 1,200 pounds of concentrates in each eight-hour shift. This is 20 in one, and runs 65 to as high as 73 per cent. tungsten.

The Ima is situated 55 miles northerly from Mackay, up the Blackfoot branch. It is 25 miles from Ledora, on the Gilmore line, but an inaccessible mountain lies between. Al- ready a wagon road is being constructed across this mountain, which will cut the wagon haul charge in two. At present this costs from $12 to as high as $20 a ton.

Boston, October 7.—The abandonment of the proposed mer- ger of the Calumet & Hecla Mining Company with nine sub- sidiary Michigan companies was officially announced before the close of the stock market yesterdey.

Cripple Creek, Colo, Oct. 7.—From the portal of the Roose- velt deep drainage tunnel there is at this time, as in the last six months, a flow of 5,800 gallons pouring out each minute, which permits a recession throughout the camp of about six feet a mouth. The water has receded considerably in every mine during the last six months.

Goldfield, Nev., Oct. 7.—Preliminary estimates of the pro- duction made by the Consolidated Mines Company in Septem- ber, just issued by J. F. Thorn, the general superinteudent, placed the output at 26,766 dry tons, with an estimated net recovery of $650,000, operating costs amouutiug to $225,000, and net profits of $425,000. The average gross value of all ore treated was approximately $24.50 per ton.

Nevada.—The total value of the mine output of gold, silver, copper, lead, and zinc in Nevada in 1910, according to V. C. Heikes, of the United States Geological Survey, was $34,152,- 148, as against $30,072,932 in 1909, showing an increase of $4,079,216, or over 13.5 per cent.

The total production of gold in 1910 was 913,265.05 fine ounces, valued at $18,878,864, a gain of $2,638,991, or 14 per cent. over the 1909 productiou. Of the gold output 7,854.70 fine ounces came from placers (mainly in Nye Couuty), 880,- 180.93 ounces from siliceous ores, 21,230.87 ounces from copper ores, and 3,998.55 ouuces from lead, zinc, copper-lead, and lead-zinc ores. Siliceous ores yielded over 96 per cent. of the entire gold production. From bulliou in gold and silver mills were recovered 728,139.67 fine ounces, concentrates pro- duced 76,696.62 fine ouuces, and crude ore shipped to smelters contained 100,574.06 fine ounces.

Colorado.—The total value of the miue output of gold, sil- ver, copper, lead, and zinc in Colorado in 1910, according to

Charles W. Henderson, of the United States Geological Survey, was $33,673,879, against $33,907,140 in 1909, a decrease in value for 1910 of $233,261.

The production of gold showed a decrease of 71,505.20 fine ounces and of $1,482,278 in value; the output of silver, a decrease of 393,035 ounces and of $34,186 in value; the production of copper, a decrease of 2,632,511 pounds, and of $3[illegible] 205 in value. The output of lead, however, showed an increa[illegible] of 3,903,483 pounds and of $243,921 in value; and the p[illegible] duction of zinc (figured as spelter), a notable increase of [illegible] 879,388 pounds and of $1,397,487 in value.

COMPANY NOTES

CALUMET AND HECLA.

Directors Review Contest—Announcement of Plan Followed by Much Hostile Litigation—The Various Suits in Detail—Laurium Vote Purposely Held Back.

To the Stockholders of the Calumet & Hecla Mining Company:

Your directors submit the following statement in regard to the proposed consolidation of the Seneca Mining Company, Ahmeek Mining Company, Allouez Mining Company, Osceola Consolidated Mining Company, Centennial Copper Mining Company, Tamarack Mining Company, Laurium Mining Company, La Salle Copper Company, Superior Copper Company, and Calumet & Hecla Mining Company, which consolidation they have decided must now be abandoned.

On January 2nd, 1911, the directors of the several companies named caused to be sent out notices of special meetings of the stockholders, to be held on the 7th, 8th, and 9th days of March, to consider the question of the consolidation of those companies upon terms stated in circular letters sent with the notices of the meetings. Just prior to March 7th Godfrey M. Hyams brought suit as a stockholder of the Osceola Company in the United States Circuit Court, and obtained a restraining order forbidding the carrying through of the consolidation until a hearing should be had. Informal votes were taken at the meetings, and the result showed that the stockholders of the several companies favoured the consolidation, and the meetings were adjourned to the 24th, 25th, 26th, 27th, and 28th days of April, on which dates they were adjourned to the 1st, 2nd, 3rd, 4th, and 5th days of May.

A second suit was brought in the Circuit Court of Michigan for the County of Ingham by Charles M. Turner and others, also as stockholders of the Osceola Company, and later a third suit was brought by Frederick W. Denton as a stockholder of the Ahmeek Company in the Circuit Court of the State of Michigan for the County of Houghton, and similar orders obtained. On or about May 1st Waldemar A. Chadbourne, as special administrator of the estate of Thomas L. Chadbourne, intervened in the Denton suit.

The stockholders of all the companies except the Laurium Company then voted for the consolidation, and the meeting of the Laurium Company adjourned without action, so that the companies would not be so irrevocably committed that they could not be disentangled, if the opponents of the consolidation should be able to defeat it by interposing so much delay that it would become practically impossible to carry it into effect.

Hearings were had in each of the three suits mentioned, resulting in a denial of the application for a temporary injunction by Judge Swan in the Hyams suit and by Judge Streeter in the Denton-Chadbourne suit, and the granting of a temporary injunction in the Turner suit, Judge Wiest holding, contrary to the opinions of Judge Swan and Judge Streeter, that the questions involved in deciding whether the terms proposed were fair, were too difficult to be determined upon affidavit, and that, although the authorized capital stock of the new company was fixed at $10,000,000, inasmuch as the property with which it would begin business would have a value larg[illegible] in excess of $10,000,000, the consolidation would be a violat[illegible] of the statute which fixes a maximum limit of $10,000,[illegible] upon the capital stock of mining companies.

After the decision by Judge Streeter in the Denton-Ch[illegible] bourne suit, that case was taken by the complainants to t[illegible] Supreme Court of Michigan by a petition for a writ of ma[illegible] damus, and a restraining order issued pending the decision [illegible] the court.

On August 10th a fourth suit was brought by John F. Ja[illegible] son as a stockholder in the Ahmeek Company in the Unit[illegible] States Circuit Court, and a restraining order obtained, and [illegible] order to show cause why a temporary injunction should n[illegible] issue was made, the hearing on which is now pending.

Your directors are advised by counsel that they cannot sta[illegible] when final decisions either for or against the proposed co[illegible] solidation may be had.

The consolidation was proposed to the stockholders of t[illegible] several companies because through a consolidation, and on[illegible] through a consolidation, could certain large economies in ope[illegible] tion and the greatest conservation of mineral resources be o[illegible] tained. It has, however, been manifest from the beginni[illegible] that delay in carrying out the consolidation would alone, [illegible] of sufficient length, compel the abandonment of the plan. O[illegible] method of operating should be adopted if the properties are [illegible] be managed as one large enterprise, and another method if t[illegible] properties are to remain as single units. In fairness to t[illegible] individual properties the decision as to which method is to [illegible] adopted cannot be delayed beyond a certain time. In voti[illegible] for the consolidation, some date had to be fixed as of whi[illegible] the consolidation should take effect. From this date all div[illegible] dends upon the stock of the consolidated company had to [illegible] equalized, and, if the consolidation could not be put in[illegible] operation and if the savings therefrom could not be made, the[illegible] then payment of such equalizing dividends on the consolidate[illegible] stock allotted to the now unprofitable mines would shortly pu[illegible] a serious and unfair burden on certain of the profitable com[illegible] panies. The date fixed from which this equalization shou[illegible] take place was March 15, 1911.

Moreover, since the proposed plan of consolidation was sub[illegible] mitted to the stockholders, the work incident to the vario[illegible] suits has taken such a large part of the time of the officers [illegible] the company as to amount to a serious interference with the [illegible] work in operating the properties, and further continuation [illegible] the litigation promises to involve even greater sacrifices [illegible] time.

Because of the great advantages that would result from [illegible] consolidation your directors have felt it their duty to th[illegible] stockholders of all the companies to go on with the plan unt[illegible] it became entirely clear that it should be abandoned. Th[illegible] time, in the opinion of your directors, has now arrived, an[illegible] they have therefore, instructed Messrs. Shaw, Agassiz, an[illegible] Flagg, as proxies of this company, to vote against the consol[illegible] dation at the meeting of the stockholders of the Laurium Com[illegible]

pany called for November 16th, 1911, and have instructed the officers of this company to take such steps as may be necessary to wind up the present litigation.

In the course of the litigation sensational statements have been made, in affidavits and elsewhere, attacking the value of the property of this company. These statements have been made by persons unfamiliar with the conditions and operations of this company and are without foundation in fact. They need cause the stockholders no uneasiness. The further study of the subject made necessary by the allegations in the several bills of complaint has confirmed your directors in the belief that the valuation of this company's property as compared with the valuations placed upon the properties of the other companies was conservative and fully borne out by the actual conditions.

The statements that have been made attacking the value of the property of certain of the other companies have not changed the opinion of your directors as to the wisdom of this company's continuing as a stockholder in the various mines. Every effort will be made to secure the best results from the individual properties.

Copies of the several bills of complaint and the answers thereto will shortly be on file at the office of the company and open to inspection by the stockholders of all the companies.

Quincy A. Shaw,
Rodolphe L. Agassiz,
Francis W. Hunnewell,
Francis L. Higginson,
James MacNaughton.

Boston, October 6th, 1911.

HILLCREST DIVIDEND.

The regular 1¾ per cent. dividend has been declared on Hillcrest Collieries, preferred.

It is payable on October 14th to holders of September 30th.

Some time ago some of the directors had apparently made up their minds that no dividend would be paid, although there was sufficient money in the treasury to meet it.

As is well known, the company has been tied up for months as a result of the strike, but once the labour troubles are over it is figured that the concern will be a good money-maker.

CROWN RESERVE DIVIDEND.

Crown Reserve has declared the usual monthly dividend of 2 per cent., with 3 per cent. bonus, payable November 15th to holders of October 31st.

TEMISKAMING-HUDSON BAY'S ANNUAL REPORT.

For the fiscal year ending August 31st, the Temiskaming and Hudson's Bay Mining Company shipped 676.32 tons of ore, with an average assay of 1,191.10 ounces to the ton, a total of 805,572.88 ounces. Of this amount 214.08 tons were estimated as high-grade ore with an average assay of 2,417.87 ounces, while the balance of 462.24 tons is classed as low grade, with an average assay of 587.88 ounces to the ton, which latter figures are rather high for low grade shipments from the camp. In addition to this 16,884.47 ounces of bullion was sent away from the property.

During the year the new mill, which was running since March, treated 11,109.6 tons of ore. The table of concentrates produced is as follows:

	Tons.	Silver contents.
Jigs	153.18	168,271.40
Sands	146.99	111,267.70
Slimes	109.01	35,681.70
Nuggets ..lbs.	240	2,400.00

The average assay a ton of this mill production was 776.23 ounces, and the total value was $147,409.36.

In concluding his report to the directors at the annual meeting Manager Horace G. Young says: "I may say that your properties are in good order. There is sufficient ore in sight to warrant an equally good production this year as the one just ended."

ONTARIO EXPLORATION STATEMENT.

Canadian shareholders of the Northern Ontario Exploration Company, Limited, have been supplied by the secretary of the company in London, with a copy of the balance sheet at June 30th last and the profit and loss account from the registration of the company on January 17th to the same date.

The covering letter states that since June 30th options at par have been exercised on 9,100 more shares of the stock, and that the balance of the unissued capital (280,571, one-pound shares) is under option to the subscribers of the original working capital, also at par. Also since June 30th the company has taken a $25,000 interest in the Poreupine Veterans Exploration Company and other important deals are under negotiation.

It will be noted that no general information is vouchsafed as to the identity of large shareholders. The full statement is as follows:—

LAKE SUPERIOR CORPORATION.

The Lake Superior Corporation has issued its annual report for year ending June 30th, 1911. It shows that the yearly operations of the subsidiary companies resulted in a surplus of $1,200,216, subject to depreciation and other charges.

The output of the steel plant was very satisfactory and compares with 1910 as follows:

	1910	1911
Pig iron	$ 53,528	$170,359
Steel rails	201,615	208,283

The production is the highest ever attained, despite certai difficulties. The entire programme of new construction, a originally planned having been carried out, the directors d not contemplate for the moment moving to any great extent i the direction of making further capital expenditure, excep what must be incurred to put the finishing touches to wha they believe to be one of the best equipped and well balance plants on the continent. The outlook is decidedly encouragin

GLOBE AND PHOENIX.

The Globe and Phoeniix issues an interim report for the hal year to June last, at which date the ore reserves were estimat ed at 179,000 tons, of a gross value of £1,356,238. The min would appear to be developing satisfactoriily, and during th half year the substantial gross profit of £181,868 was secured The machinery is working satisfactorily, with the exception o the sands plant, but this has been closed down pending th erection of a new roasting plant, which is to cost £34,500. Mr Piper's concluding remarks are: "From the report you wil see that the prospects of the mine leave nothing to be de sired, and that substantial profits are assured for some years.' Under these circumstances we can only congratulate the hold ers of Globe and Phoenix.

STATISTICS AND RETURNS

COBALT ORE SHIPMENTS.

Following are the shipments from the Cobalt camp for the week ending September 29th, and those from January 1, 1911, to date:—

	Sept. 29. Ore in lbs.	Since Jan. 1. Ore in lbs.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining gineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show s of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a rough knowledge of Mining Law, should be very careful with whom they place their business.

DEPARTMENT OF MINES. GEOLOGICAL SURVEY.

PUBLICATIONS

The Geological Survey has published maps and reports dealing wit a large part of Canada, with many local areas and special subject

A catalogue of publications will be sent free to any applicant. A single copy of a map or report that is specially desired will b sent to a Canadian applicant free of cost and to others at a nominal price. The applicant should state definitely the precise area co cerning which information is desired, and it is often of assistance in filling an order for a map or report if he states the use for whic it is required.

Most of the older reports are out of print, but they may usually be found in public libraries, libraries of the Canadian Minin Institute, etc.

REPORTS RECENTLY ISSUED:

CANADA

1085. Descriptive Sketch of the Geology and Economic Minerals of Canada. Accompanied by a geological and mineral map Canada, by G. A. Young and R. W. Brock.
1170. Summary Report of the Geological Survey for 1910.

NEW BRUNSWICK and NOVA SCOTIA

1113. Memoir No. 16. The Clay and Shale Deposits of Nova Scotia and portions of New Brunswick, by H. Ries aud J. Keele.

QUEBEC

1110. Memoir No. 4. Geological reconnaissance along the line of the National Transcontinental Railway in Western Quebec, b W. J. Wilson, accompanied by a map.
1064. Geology of an area adjoining the east side of Lake Timiskaming, by Morley E. Wilson.

ONTARIO

1091. Memoir No. 1, Geology of the Nipigon Basin, Ontario, by A. W. G. Wilson.
1137. Memoir No. 10. An instrumental survey of the shore-lines of the extinct lakes Algonquin and Nipissing in South-wester Ontario, by J. W. Goldthwaite.

NORTH WEST PROVINCES

1115. Memoir No. 8. The Edmonton Coal Field, Alberta, with maps, by D. B. Dowling.

BRITISH COLUMBIA

1139. Memoir 11-T Triangulation and Spirit Levelling of Vancouver Island, 1909, by R. H. Chapman.

YUKON and NORTH WEST TERRITORIES

1080. Report on a part of the North West Territories drained by the Winisk and Attawapiskat Rivers, by Wm. McInnes.
1006. Report on a traverse through the southern part of the North West Territories from Lac Seul to Cat Lake in 1902, b A. W. G. Wilson.
1130. Memoir No. 9. Bighorn Coal Basin, Alberta. by G. S. Malloch, accompanied by a map.

MAPS RECENTLY ISSUED:

1149. Map 21A. Saanich sheet, Vancouver Island, B.C., topographical. Scale 1 mile to 1 inch.
1164. Map 28 A. Sketch map of Portland Canal Mining District.

YUKON and NORTH WEST TERRITORIES

1089. Map 9A. Explored Routes on Parts of the Albany, Severn and Winisk Rivers. Scale 8 miles to 1 inch.

NOTE.—Maps published within the last two years may be had, printed on linen for field use. A charge of 1 cents is made for maps on linen.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economi geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature re ported upon. Letters and samples that are of a Departmental nature, addressed to the Director may be mailed O.H.M.S. free of postage

Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.

BRITISH COLUMBIA

The Mineral Province of Western Canada

Has produced Minerals valued as follows: Placer Gold, $71,213,103; Lode Gold, $60,811,067; Silver, $31,095,602; Lead, $24,645,605; Copper, $60,743,405; Other Metals (Iron, Zinc, etc.), $1,083,172; Coal and Coke, $114,012,556: Building Stone, Brick, etc., $10,593,100; making its Mineral Production at the end of 1910 show an

Aggregate Value of $374,197,650.

In 1910 the quantity of Ore mined was 2,216,428 tons, and of coal 3,139,235 long tons. The value of Minerals produced that year was: Placer Gold, $540,000; Lode Gold, $5,533,386; Silver, $1,245,016; Lead, $1,386,350; Copper, $4,871,512; Coal and Coke, $11,108,335; Other Minerals, $1,692,473, making the

Total Value for 1910, $26,377,066.

Lode mining has only been in progress for about eighteen years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those in any other Province in the Dominion, or any Colony in the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with mining Reports and Maps, may be obtained gratis by addressing

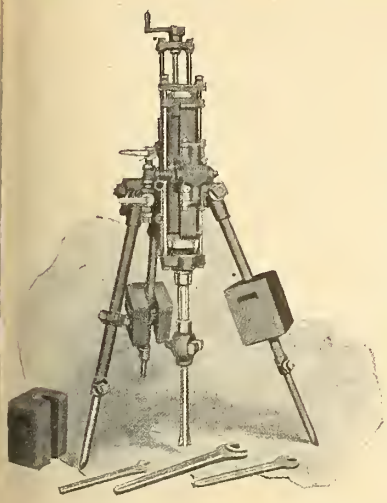
NEW WIZARD ROCK DRILL



We handle the New Wizard Rock Drill, which will drill a greater number of feet per day, per month, or per year, with less power consumed per foot drilled, than any other piston rock drill of like size now manufactured.

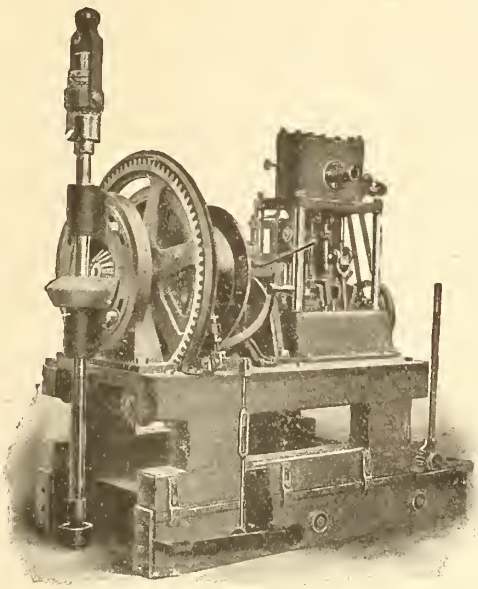
HAMMER DRILLS AND STOPING DRILLS

We handle a complete line of hammer drills and stoping drills for all sorts of mine and quarry work.

Send for information about these drills.

THE TERRY SHOT DRILLS

The Terry Shot Drills will bore any depth to 4,000 feet; will cut any size core up to 30 inches.



Will bore at any angle up to 45 degrees; can be operated by steam, gasoline, electricity or air.

Also Air Compressors any type or size.
Pumps any type or capacity.
Hoists, steam or electric.
Boilers, Water Tube or Horizontal Return Tube.
Complete mining and quarry equipment.

CANADA FOUNDRY COMPANY
LIMITED

212 KING STREET, WEST - TORONTO, CANADA

OFFICES AT

HALIFAX MONTREAL OTTAWA COBALT WINNIPEG CALGARY NELSON VANCOUVER

Province of Quebec

Department of Colonization, Mines, and Fisheries.

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, Etc.

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

MINERS' CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. Th price of this certificate is $10.00 and it is valid until the first of January following. This certificate gives the right to prospect o public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to th extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his right must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cent an acre per year and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavi that during the year work has been performed to the extent of at least twenty-five days labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $10 an acre fo SUPERIOR METALS when more than 20 miles distant from a railway and $20 an acre when less than 20 miles.

For INFERIOR METALS the prices are $2.00 and $4.00 an acre respectively.

The attention of prospectors is specially called to the territory in the North-Western part of the province of Quebec, north of th height of land, where important mineralized belts are known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY 228 ST. DENIS STREET, MONTREAL, for the determination, assays and analysis of minerals at very reduced rates for the benefit o miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensur results of undoubted integrity and reliability.

The Bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of th Province, on application addressed to

THE HONORABLE THE MINISTER OF COLONIZATION, MINES, AND FISHERIES, QUEBEC.

Nova Scotia Mines

Gold, Coal, Iron, Copper, Lead, Tin, Manganese, Tungsten, and other minerals.

The Gold District covers more than three thousand square miles. Millions of dollars worth of gold have been taken from the gold fields of Nova Scotia and millions of dollar's worth remain for recovery.

Gold mining in this Province offers good inducement for investment. Labor is cheap and plentiful: timber and fuel are abundant.

Large deposits of iron also are known to exist at various places in the Province; and considerable mining has been done in connection with this mineral, the ore being used locally and shipped to foreign ports.

Among the most important minerals occurring in economic quantities may be mentioned, Coal, Gold, Silver, Manganese, Leadsilver, Copper, Barytes, Mineral Pigments, Gypsum and Tungsten.

Licenses are issued for prospecting for Gold and Silver for a term of twelve months.

The licenses are for areas 150 by 250 feet, and can be obtained for 50c. an area.

Leases can be secured for $2. an area, for a term of forty years; subject to annual rental of 50c. an area.

Licenses to search over five square miles, for a period of eighteen months, for minerals other than gold and silver, cost $30.

Leases for three renewable terms of twenty years each can be obtained for $50., and are subject to a yearly rental of $30.

Royalties are as follows:—

Gold, two per cent on the gross value thereof; Copper, four cents a unit; Lead, two cents a unit; Iron, five cents a ton; Tin and Precious Stones, five per cent; Coal, ten cents on every long ton sold or removed from the mine.

Copies of the mining law can be had gratis, by applying to the Department of Public Works and Mines, Halifax, Nova Scotia, or to Mr. John Howard, Agent General for Nova Scotia, 57a Pall Mall, London, England.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

WANTED

AGENCY FOR ORES AND MINERALS.

An Ore Merchant who has connections with all the blast-furnaces and electro-metallurgical firms of France desires to communicate directly with firms who produce or sell:—

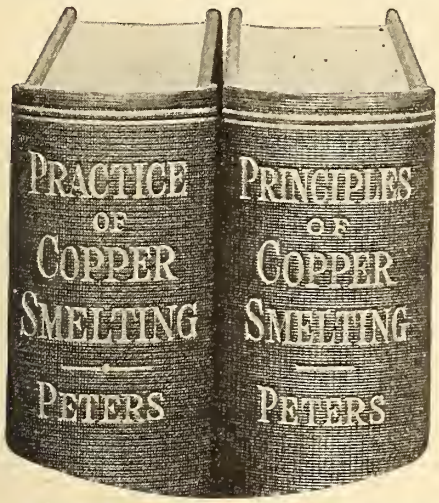
Chrome Ore; India, Brazil, or Caucasus Manganese Ores; Graphite; Tungsten Ores; Molybdenite Antimony Ores; Iron Ores; and Asbestos.

It is desired to purchase Ores outright, or to take over Sales.

AGENCY FOR FRANCE:—

Address—Mr. Ch. CHAUTEN,
123 Rue Lamark, PARIS.

Leading New Books



By Dr. Edward D. Peters, Professor of Metallurgy, Harvard University.

Practice of Copper Smelting.

693 *pages*, 6x9, *illustrated*, $5.00 (21*s*).

This third big work by Dr. Peters, supplanting "Modern Copper Smelting," puts in book form the latest methods of copper smelting.

It describes the best present-day practice in leading plants.

It is the result of a recent thorough investigation in which the author had the hearty co-operation of the metallurgists in the various large plants.

It is complete and authoritative.

Metallurgy of Tin

HENRY LOUIS, M.A., D.Sc.

138 *pages*, $2.00 (8/6)

A valuable book for producers of tin and manufacturers who use tin in their processes or products.

It covers properties, metallurgical principles, smelting in shafts and reverbatory furnaces, and tin plate and tin plate scrap.

This book discusses details of plant and practice only so far as is necessary to illustrate the application of the principles.

It deals chiefly with the chemistry and principles upon which the different methods of smelting are based.

The main object of this book is to present the *reasons why* instead of the *means how*.

Rock Drills

By EUSTACE M. WILSON.

367 *p.*, $4.00 (17*s*).

Compares new and standard types, suggesting the best uses for each under varying conditions.

Practical Shaft Sinking

By FRANCIS DONALDSON, M.E.

143 *p.*, $2.00 (8/6).

Covers linings, costs, contracts and methods, and is thoroughly modern.

Cyanide Handbook

By J. E. CLENNELL.

520 *p.*, $5.00 (21*s*).

Complete trea se including recent developments and discoveries.

It is used by metallurgists everywhere.

Principles of Metallurgy

By CHAS. H. FULTON.

536 *pages*, $5.00 (21*s*).

A modern treatment of fundamentals.

It has been received enthusiastically everywhere.

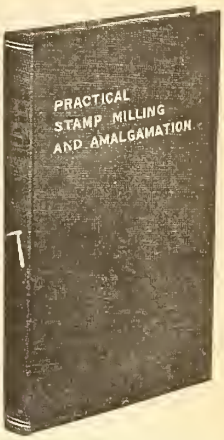
FOR THE MILLMAN

Practical Stamp Milling and Amalgamation



By H. W. MacFARREN

166 PAGES INDEXED

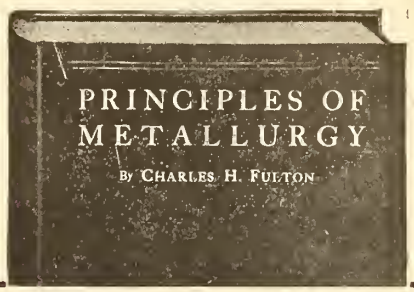
$2 POSTPAID

Written primarily for the millman himself, this book will prove of value to all those having to do with the milling of gold ores. Gives details needed in everyday work. The stamp mill, its location, and design; the mortar, die, shoes, tappet, and cam; adjustment of height, order of drop, feeder, and screens; water supply and power; principles of amalgamation and treatment of plates; retorting; loss of gold, mill tests, and mill management; all these are treated in an illuminating manner by one who has himself solved the problems.

Book Department

CANADIAN MINING JOURNAL

TORONTO



THE standard treatise in English on general metallurgy. It is of the highest value and greatest practical use to every metallurgist. The sections on Alloys, Measurements of High Temperatures, Slags and Mattes are very important.

The author is President and Professor of Metallurgy, at the South Dakota School of Mines.

The Main Chapter Headings Are:

I.—The Metals and Metallurgy from the Historic Point of View. II.—Physical Mixtures and Thermal Analysis. III.—Physical Properties of Metals. IV.—Alloys. V.—The Physical Properties of Alloys. VI.—The Measurement of High Temperature. VII.—Typical Metallurgical Operations. VIII.—Slags. IX.—Matte, Bullion and Speiss. X.—Refractory Material for Furnaces. XI.—Fuels. XII.—Combustion. XIII.—The Production and Heating of Blast Furnaces. XIV.—An Example Illustrating the Physics and Chemistry of a Melting Operation. The Blast Furnace for Copper.

536 pages, 6x9, 188 illustrations, $5.00 (21s) net, postpaid.

THE "ROYAL LINE"

To Europe in

Less than Four Days

LAND TO LAND

The St. Lawrence Route to Europe by the ROYAL LINE shortens the ocean voyage to less than four days, and affords the traveller two days of delightful, sheltered sailing down the great St. Lawrence with its never ending panorama of beautiful scenery and historically famous points. The splendid triple turbine steamers

ROYAL GEORGE and ROYAL EDWARD

hold all speed records and afford the most luxurious accommodation in the Canadian-European service. The English Port, Bristol, is only two hour's run to London by the special boat trains which meet the Royal Line Steamers on arrival.

For further information see nearest Steamship Agent, or the Canadian Northern Steamships Limited.

MINING AND SCIENTIFIC PRESS

Controlled by T. A. Rickard | Established 1860 | H. Foster Bain, Editor | Published weekly | Thomas T. Read, Associate Editor

In every issue valuable articles are published on mining, metallurgy, and geology, the latest news from special correspondents at the principal mining centers, letters giving the ideas and experience of successful men, and other items of useful knowledge.

THE MINING MAGAZINE

Established September, 1909

T. A. RICKARD, Editor — **Published monthly at London, England**

A monthly magazine is the natural corollary of a technical weekly. It permits of more deliberate and more extended notice of matters concerning which the news element is less important.

The Mining Magazine includes a review of the world's progress in mining, metallurgy, and economic geology, written by men who have personal knowledge of the regions and conditions discussed.

CENTRIFUGAL PUMPS

DRIVEN BY

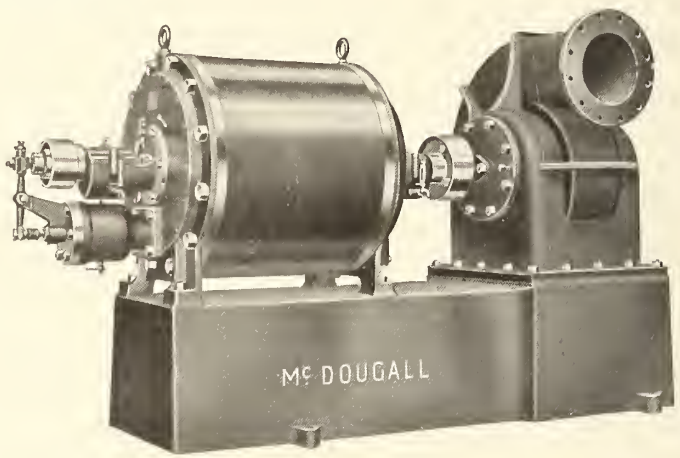
STEAM TURBINES

FOR

MINING PURPOSES

For keeping mines free from water and for creating hydraulic power for placer mining, the turbine-driven centrifugal pump in its present development is peculiarly applicable. The very small dimensions of such sets would commend their use where space conditions are important without very deep inquiry into their other virtues. Turbine pumps can be started up at any time from a cold condition and once started operate for an indefinite time until stopped by the simple closing of the throttle valve.

As a means of propulsion for centrifugals no machine has yet been devised which fills the bill as satisfactorily as the small steam turbine. Because of its superior range of speed it is possible to get a unit of much smaller diameter than would be necessary in a larger pump driven by a reciprocating engine, To those unfamiliar with the modern turbine and the centrifugal pump the power and speed of these machines is almost incredible.



The illustration shows one of our 10 inch centrifugal pumps driven by a 75 h.p. Kerr steam turbine at 1800 r.p.m.

If you are interested send for

Bulletin 16—Steam Turbines. **Bulletin 108 – Centrifugal Pumps.**

A LETTER TO YOU

SUBJECT: LOWER STOPING COSTS

"We have tried Sullivan Stopers in competition with the other leading makes of hammer drills. We have found that Sullivan Stopers cost us less per foot of hole drilled, or per yard of rock taken out." "They are very rapid drillers, but take less air and fewer repairs than our other stopers."

"We have learned that our bill for broken drill bits is smaller on Sullivan Stopers, and that they are more popular with our men, because they rotate easier, run in better balance and have less jar and vibration than any of the other stopers we have tried."

"We shall buy Sullivan Stopers exclusively after this."

This letter was written in our own office. It is a composite letter—the opinion of mining companies in all parts of the United States, Canada, and Mexico, as reported direct to us and backed by repeated purchases of DA-21 Sullivan Stopers.

Write any of our offices for the names of these concerns and details of their experiments; or better still, ask for one or more drills for a free trial in your own mine.

Amatite ROOFING

FOR MINE BUILDINGS

AMATITE is exactly suited to mining buildings because:

1—It can be laid by unskilled labor.

2—It has a real mineral surface *which requires no painting.*

3—Its cost is lower than that of other ready roofings of less weight.

4—It comes in rolls ready to be unrolled on the roof and nailed down.

5—The necessary nails and cement are supplied free, packed handily in the centre of each roll.

The mineral surface of Amatite is somewhat of a novelty: and the fact that it obviates the old painting nuisance, is giving to this roofing the leadership of the ready roofing industry.

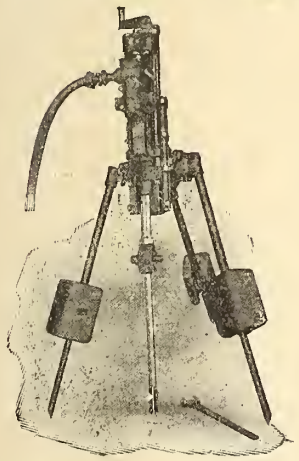
The surface consists of mineral particles embedded under great pressure into a tough plastic matrix of pitch.

A sample of Amatite will be sent free on request.

The Paterson Mfg. Co., Ltd., Montreal, Toronto Winnipeg, Vancouver, St. John, N B. Halifax, N. S.

"LITTLE GIANT"

ROCK DRILLS



Simplicity in rock drill designs may be as undesirable as intricacy, if carried to excess.

"Rand Little Giant Drills" are symbolic of "Intelligent Simplicity."

The number of parts in the "Little Giant" is reduced to the efficiency limit and each part is perfected both in design and material.

Mere simplicity is detrimental to efficiency, economy and endurance, and becomes expensive when not applied with intelligent experience.

Why the C.P.R. North Toronto Route to Ottawa and Montreal is the Logical One

The train leaves as follows:

Leave North Parkdale - - -	9.15 p.m.	Leave West Toronto - - - -	9.30 p.m.
Arrive North Toronto - - -	9.40 p.m.	Leave North Toronto - - -	10.00 p.m.
Arrive Ottawa, 6.50 a.m.		Arrive Montreal, 7.00 a.m.	
Daily.		Double Electric Berth Lights.	

¶ The residents of Toronto are adjacent to either North Parkdale, West Toronto or North Toronto stations, same being easily accessible and close to residential districts.

¶ The North Toronto route is over an hour faster and overcomes a long hill climb for the train out of Toronto obviating any inconvenience and ensuring early arrival at Montreal and Ottawa.

¶ The roadbed has been improved till it is unexcelled in Canada. Practically half the line is double tracked.

¶ The equipment is "Canadian Pacific Standard," a synonym for the "best" and attentive porters, ensure efficient service.

MINE TIMBER.

The serious consideration of the fact that Canada's available supplies of mine timber are rapidly vanishing is forced upon us. The data collected by Messrs. MacMillan, Robertson, and Boyce for the Dominion Forestry Branch, represent the first attempt to define the present situation.

During the past year, mine timber to the value of $827,337 was used in Canada. 52,848,000 linear feet of round timber, valued at $523,339; and 22,305,000 board feet of sawn timber, valued at $303,908, made up the total. The average cost of the former was $9.90 per thousand linear feet, and of the latter $13.63 per thousand board feet.

Of the round timber, British Columbia used 55 per cent. The average cost per thousand linear feet was $7.01. Nearly all this was Douglas fir, 20,000,000 feet of which was of four to six inch diameter, used as lagging in coal mines. This accounts for the low average cost.

Nova Scotia used 30 per cent. of the round timber, or 15,653,000 feet, the average cost of which was $10.74 per thousand. Most of this timber was five inch spruce.

Alberta's consumption, 7,484,000 feet, consisted largely of lodge-pole pine, supplemented by spruce and small quantities of Douglas fir. The average cost was $17.75.

Ontario's mines are credited with only 549,000 linear feet, costing $26.83 per thousand. About one-half of this was five to seven inch spruce; while one-third was pine of small diameter.

Although twelve species of wood are reported, only two are used in important quantities. These are Douglas fir and spruce, used respectively in the coal mines of British Columbia and Nova Scotia.

As regards sawn timber, practically the same proportions hold as for round.

Timber used in mining has shorter life than when used overground. Underground conditions are conducive to decay. The danger of fire in coal mines is an added risk. Hemlock has a life of about five years in its natural condition. Spruce lasts only three years. When treated with creosote or zinc chloride the durability of all species is increased from 100 to 300 per cent. An added argument in favour of such treatment is the fact that inferior woods may be successfully used.

The use of preservatives has got far beyond the experimental stage. Particularly in the United States has the subject been investigated. Practical applications have been made of results obtained. Hence,

Canadian mine operators have merely to borrow from the experience of others.

It may or may not be practicable to create and enforce legislation on this subject. There is no question, however, as to the present duty of all large consumers of mine timber. Apart from other aspects, the fact that the use of preservatives makes for economy is sufficient cause for change in the present attitude of indifference.

THE ORIGIN OF PETROLEUMS.

That tireless champion of the theory of the inorganic origin of petroleum, Mr. Eugene Coste, contributes to the last bulletin of the Institution of Mining and Metallurgy, a vigorous attack upon the supporters of the organic theory.

After asserting that the advocates of the latter theory persistently start from wrong premises, and that they thus impede progress in the solution of an important problem, Mr. Coste proceeds to flay his opponents in characteristic fashion.

To show that a substantial body of thinkers have given their support to the inorganic theory, Mr. Coste quotes such names as Berthelot, Mendeleef, Moissan, Elie de Beaumont, Humboldt, and others of high repute. Hence, it is incorrect to argue that the inorganic theory is held by chemists only. Moreover, says Mr. Coste, the one fundamental fact that the only phenomenon analogous to the production of petroleum visible to-day is in some phases of volcanism. This is entirely overlooked by the advocates of the organic theory.

Abundant evidence has been furnished by scientists to show that associated with active volcanoes and with ancient volcanic rocks are large quantities of hydrocarbon gases. Massive crystalline rocks contain as much as 0.2 per cent. of carbon. This, Mr. Coste believes, establishes the fact that the source of all carbon was far removed from the organic realm.

The oil-bearing character of strata in "petroliferous provinces" does not depend in any way upon the presence of fossils, but does depend solely upon the fact that faulting and fissuring have provided ingress for petroleum emanations from the interior. In further support of this statement, Mr. Coste cites the facts that oil is obtained even in crystalline schists and gneisses, that productive sands range from the Archaean to the Quaternary, and that the oil everywhere presents the same characteristics.

On the other hand, although the "organics" admit that the process of petroleum production must be operative to-day, they also admit that there is no visible evidence of the fact. Mr. Coste, commenting upon this, asseverates that never in nature did a petroleum production process "coeval with the kingdoms of life" exist. That there is any genetic relation between coal and petroleum he categorically denies. That methane exists both in coal and in petroleum proves merely that methane can be formed in two ways. "Although "are surrounded . . . . . everywhere with "death, decay, and decomposition of countless org- "isms, animal and vegetable, no one has yet been a "to . . . establish one single case in which th "mixtures of hydrocarbons known as petrolcums "found through the natural processes of decaying "ganisms, while its constant and abundant product "in volcanic phenomena cannot be disputed a "longer."

On two major propositions Mr. Coste lays stro emphasis. Vegetable organic remains were alwa transformed into coal, and soft organic tissues w never entombed in sedimentary rocks.

Several quotations from adherents of the orga theory are given by Mr. Coste. These show a surpr ing lack of agreement. The assumption that time a temperature compensate each other in the natural d tillation of petroleum, is laughed at. Why, asks M Coste, are coal-beds left undistilled? To believe th the mere passage of time can make up for the abse of heat is as reasonable as to assert "that by leavin "turkey long enough in cold storage, it will cook "self to the most succulent point."

Point after point is scored by Mr. Coste. These cannot touch upon. Suffice it to indicate the sev positive statements on which he bases his positi These are:—

First, bituminous shales containing bitumens petroleums, as such, never constitute widely and u formly spread sheets, nor thick horizons; they found only as isolated patches of comparatively sm extent along faults, fissures, or joints or in brecciat zones of sandy shales, and the secondary nature their bitumen is as a rule plainly evident.

Second, so-called bituminous shales, forming enti horizons in sedimentary formations, are really not tuminous shales, but are black carbonaceous sha containing the carbon as coal.

Third, even very fossiliferous strata contained wh deposited only the remains of the calcareous or si cious parts of the organisms, from which no petroleu could possibly be produced.

Fourth, petroleums as a rule are not associated wi fossils, which are themselves almost always absolute devoid of petroleum of any kind.

Fifth, the association of petroleums with sedime tary strata is one of secondary replacement.

Sixth, not only shales, but almost all other strat constitute in the unaltered sedimentary formations the oil fields, saturated impervious beds; and this i perviousness precludes the supposition that oil, gas, a water could travel through the fine pores of the sed ments, which from the time of their deposition we already occupied by water.

Seventh, the mode of occurrence of petroleum d posits in the sedimentary strata of all ages, but i certain districts only, and the constant recurrence

drocarbons in volcanic and igneous rocks, in volcanic anations, in metallic and other veins, in meteorites, comets and other stellar bodies, clearly demonstrate at petroleums are not of organic origin; if they were. eir distribution could not possibly resemble the ac- al occurrences that are known.

Without doubt, Mr. Coste has given his opponents me hard nuts to crack. The chief bar to proper dis- ssion, however, is the fundamental divergence in e postulates of each party.

We shall make it a point to inform our readers of e answers that Mr. Coste's paper is sure to evoke.

HE NEW CHAIRMAN OF THE TRANSCONTIN-ENTAL.

The Premier's selection of Mr. R. W. Leonard to fill ie important post of Chairman of the National Trans- ntinental Railway Commission, will be viewed with rofound satisfaction by all those who know Mr. Leo- ard. Particularly will the appointment appeal to ining men.

Mr. Leonard is a native of Canada. Since graduat- ig from the Royal Military College about twenty- even years ago, his professional work has consisted railroad engineering and power-plant construction, nterspersed with a certain amount of actual mining ood fortune, a function oftentimes of initiative and ision, led him to take chances in Cobalt in the earliest lays of that camp's existence. Now, as the largest older of Coniagas shares, he is able to keep several acks of wolves from his door. In fact, the emolu- nents of office will be a negligible quantity. This is y no means a disadvantage.

Apart from his attainments as a civil engineer, Mr. eonard may fairly be looked upon as a member of the ining fraternity. In addition to holding high office n the Canadian Society of Civil Engineers, he is one f the four vice-presidents of the Canadian Mining In- stitute. This position is elective, and signifies the fact hat the members of the Institute have confidence in is judgment. Moreover, he is the only member of the Board of Governors of Toronto University who has mining affiliations. This honourable post he accepted about a year ago, to fill the vacancy created by the death of Dr. Goldwin Smith.

In all probability no more arduous and ungrateful task could be conceived than that of guiding the des- tinies of the National Transcontinental Railway Com- mission. Mr. Leonard possesses at least two of the qualities that are essential to such a position. He is endowed by nature and by experience with a certain decisiveness, and with a judicial temperament. Whe- ther these qualities in themselves are, or are not, suf- ficient to carry him successfully through the admin- istrative troubles that are brewing we cannot say. He is "fortiter in re"; much will depend upon his be- coming "suaviter in modo."

From the point of view of the industry that the CANADIAN MINING JOURNAL has the honour to repre- sent, it is necessary to impress upon our readers the need of co-ordinating mining and transportation. If, in the course of his tenure of office, Mr. Leonard suc- ceeds in inducing the Grand Trunk Pacific to regard mining as THE basic industry of the country, as the one that in season and out of season will yield constant freight supplies, he will have accomplished much.

STOCK VALUE AND MINE VALUE.

Under the above caption, Dr. A. C. Lane, formerly Michigan State Geologist, now professor of geology at Tufts College, contributes to this issue the first of a series of papers in which he discusses the various factors that cause fluctuations in the value of shares, particularly shares in mining companies.

Dr. Lane takes particular pains to accentuate the inherent difference between mining shares and others, and postulates as a necessary yield for mining invest- ments an annual return of from 7 to 10 per cent. apart from amortization or return of capital.

The five elements that fix prices are, according to Dr. Lane's analysis, return, stability, marketability, ac- tivity, and control. Each of these elements is dis- cussed fully.

In view of the storm of protest aroused by Mr. J. R. Finlay's appraisal of the Michigan copper mines, Dr. Lane's articles will be timely.

We especially request our readers to send in early comments.

WEST SHINING TREE.

A preliminary report on the West Shining Tree region will be found on another page. Of seven sam- ples taken by Mr. R. B. Stewart, one contained no gold, whilst the others ranged from 40 cents to $6 per ton. As these samples were taken from different properties, it is reasonable to believe that they are characteristic of the country generally. This is not encouraging.

The mischievous practice of lauding to the skies any possible gold-bearing region must be discounten- anced. West Shining Tree will suffer. Naturally, no brief inspection can furnish sufficient evidence thor- oughly to damn a large tract. But Mr. Thompson's report will certainly dampen the ardour of the hotel- prospector who has been shouting deliriously for some months about the superlative merits of West Shining Tree.

TUBE MILL PRACTICE.

Proofs are accumulating that the best results in the employment of tube mills are obtained when the pattery produced is very coarse. At the El Oro mine, for instance, one hundred stamps crushed 360,294 tons of ore in the year ending June 30th, 1911; whereas in the preceding year two hundred stamps crushed

only 285,181 tons. One tube mill is installed for each nine stamps. As illustrating the other extreme, it may be noted that at the mill of the East Rand Proprietary only fourteen tube mills are in commission for 820 stamps, or one mill for 58 stamps.

The El Oro practice not only gives greater capacity, but effects a considerable reduction in costs.

MORE ABOUT THE GIESECKE MILL.

Late reports have it that the Rand Mines Trials Committee, after a searching investigation of the Giesecke mill, has found that the high claims of efficiency cannot be substantiated. Neither in point of capacity nor in operating costs were the hopes of the inventor realized.

Much time and more trouble have thus been saved. Had the Giesecke been placed on the market before being investigated, no doubt many operators would have given it a trial. Now, however, very few customers will be found for a device that has been officially declared uneconomic.

A CORRECTION.

The retirement of Mr. Harold Kingsmill from the management of the Rea mine, Porcupine, gave rise to several damaging rumours as to the physical condition of that mine. We have been requested by Mr. Kingsmill to state plainly that his only reason for leaving was that he wished to accept a far more remunerative billet. Not the slightest unpleasantness had occurred.

Mr. Kingsmill requested us further to quote him as being responsible for the statement that the mine is in good condition and that no discouraging features have been encountered. The bringing in of a promising body of low grade ore has added to the possibilities of the mine.

We give these statements publicity for the reason that irresponsible story-tellers have attributed to Mr. Kingsmill assertions that reflected not only on the mine but also on Mr. Kingsmill's discretion as an engineer.

EDITORIAL NOTES.

The official estimate of the gold resources of Rand is two billion pounds sterling. With an ann output of £40,000,000, this gives a life of 50 years o the Rand proper.

That sanguine person, Col. L. R. Stuart-Weather accuses some person or persons unknown of hiding "discoveries" at Porcupine. The Colonel is so what original. In his breezy way he assures the p lic that he has nothing to sell. This may be ta in two senses.

Mr. T. A. Rickard's letter in this issue serves directly to press home the need of more publicity Nova Scotian gold mines. The report of a carefu chosen commission is needed and needed badly. Ma Montreal and Toronto investors would willingly ta a shot at Nova Scotia if they had authentic inform tion.

Yukon's gold output for the current year is uno cially estimated at $4,650,000. This is a gain of $40 000.

The parabolic curve described by Kerr Lake sha is unusually marked. On a share capital of $3,000,0 the mine has paid dividends amounting to $3,720,0 The par value of the shares is $5. The market pr of these shares has fluctuated between $11 (Janua 1910), and the present figure, $3. The manageme has never taken the public into its confidence. Th essentially narrow policy usually brings its own ward. Dividend rates reached a maximum of 42 p cent. in this present year of grace. Yet the sha decline.

Sir James Whitney is being maligned for lack initiative in devising means for opening up northe Ontario. The most practical retort that could be ma would be the construction of good roads where th are most needed. A good road to Gowganda wou be a fine starter. Farming follows mining. Mini cannot expand without transportation.

CORRESPONDENCE

GOLD MINING IN NOVA SCOTIA.

The Editor:—

Sir,—In your issue of September 15th you refer to the report made by me in 1905 for the Government of Nova Scotia, and you state that "the colour of the report is not known to the public." It may simplify matters and save controversy if I quote the last paragraph of the letter accompanying my official report, as it summarizes my views on the subject.

"The conclusion which I formed from the sifting of all the evidence obtained, is that there is a geologic similarity to Bendigo, as regards the gold-bearin quartz, for in both cases the miner has encounter 'saddle reefs' or anticlines of quartz; but there a differences so great between the two districts as destroy the economic value of the structural likenes The occurrence of ore capable of yielding a reasonab profit, say, a stoping-width of 6 or 8 dwt. per ton, is scanty in Nova Scotia as to render invidious the cor parison with Bendigo; and, as far as is known, there no justifiable expectation of such persistence of goo ore in depth within the northern goldfield as in th

the Antipodes. Gold mining on a large scale has rely proved profitable in Nova Scotia, and the likelihood of developing such enterprises has been decreased the events of recent years, because these have indicated the improbability of a repetition of ore-shoots the underlying quartz formations. By 'ore' I mean old-bearing quartz from which, under existing conditions, a profit can be won. On the other hand, it is y opinion that mining operations on a small scale, rried out by working miners, without the investment of large sums of money, either in equipment or xploration, but based upon local knowledge and skilful prospecting, are likely to prove remunerative. I not endorse the attempts made (chiefly by those ho spend large amounts of money lavishly, and too ften improvidently, in undertakings not founded on areful preliminary investigation) to belittle the local ndicates and parties of lessees who have found and orked most of the profitable mines of Nova Scotia, nd I advise that the policy of the Department be so aped as to encourage this form of domestic enterrise. It is upon such that the future of gold mining in ova Scotia must depend; as it has done, for the most art, in the past."

Surely any responsible person can see the report nd the covering letter by applying to the Minister for lines at Halifax.

T. A. Rickard.

London, October 5.

THUNDER BAY DISTRICT.

The Editor Canadian Mining Journal:

Sir,—I note in your editorial, in the issue of 15th ast., regarding the twentieth annual report of the ntario Bureau of Mines, that you say, "Mr. N. L. owen's description of the Thunder Bay silver district ill stir up interest in that historic mining country." And that you "quite concur in the belief that the istrict is worthy of attention."

I have not seen Mr. Bowen's article; but I am pleased o know that the Thunder Bay silver district has, at ast, begun to attract some attention. It was the misfortune of this district that it was discovered 25 ears too soon.

Speaking of the small group of mines lying to the outhwest of the city of Port Arthur, this section of he district first began to attract attention about 1885. Considering the amount of development and explorary work done, the results obtained were certainly uch as to warrant a more systematic and extensive levelopment than then obtained. This section of the listrict had about the year 1888 five shipping mines all roducing high grade silver ore.

All the silver produced in Ontario, in the late nineties came from this district. The writer from 1888 until 1890 had charge of one of these mines, which produced in this period upwards of $300,000 worth of silver. At least one other mine exceeded this production in the same period.

The transportation problem at this time was a serious one, as all supplies and ore had to be freighted by team from 25 to 40 miles.

The mines were all closed down about 1890, before the completion of the railway through the district, and they have been practically closed to the present time. Such efforts as have been made to revive the industry were made in a way to discredit rather than revive it.

This silver field is a large one. It is the belief of the writer, based on a wide knowledge and experience gained in the 21 years that have intervened since the closing of these mines, that there is a good chance for success.

Had the mines, and the whole district, been as thoroughly explored, and the mines operated as persistingly and in as up-to-date a manner as now prevails in Cobalt, the history of the district would be another story.

However, the deposits are still here, awaiting the prospector and investor.

Yours truly,

Herbert Shear.

October 20th, 1911, Port Arthur, Ont.

THE LAY MIND.

Editor Canadian Mining Journal:

Sir,—In the current issue you suggest that the "lay mind" does not recognize that profits come to those who enter the mining business. As a matter of information, it would be of great interest if you could let your readers know how far the individuals who put up money for the Centre Star group were rewarded. In the last annual report of the Canadian Mining & Smelting Company it is stated that the Centre Star group has produced minerals to the value of $21,488,745. The "lay mind" would greatly appreciate your statement as to how this value was distributed among those who took part in its production. The same question applies to the production of St. Eugene mine, which is given in the report as $10,394,520.

Yours faithfully,

G. C. Biggar.

Toronto, Ont., October 18th, 1911.

TIMBER USED IN MINING OPERATIONS

Compiled by H. R. MacMillan, M.F., assisted by Bruce Robertson and Guy Boyce.
Courtesy of Dominion Forestry Branch.

The statistics of the timber used in the mines of Canada in 1910 are based upon reports received from 136 coal and ore mines throughout the various provinces, as follows: British Columbia, 59; Ontario, 27; Alberta, 20; Nova Scotia, 15; Yukon Territory, 9; Saskatchewan, 4; Manitoba, 2. These represent practically all the mines using timber in any quantity. There are a large number of mines in Canada which do not use timber in their operations.

In the tables two main divisions have been made, viz.: round timbers, and sawn timbers. The round timbers are used underground to give artificial support for insecure roofs or walls and to protect shafts, drifts, and gangways. The sawn timber reported is mostly

lumber, together with a small quantity of square timber, and was used principally above ground for buildings, breakers, tipples, washers, and trestles. A small quantity was used underground for sets, stulls, and ventilator shafts.

Including round and sawn timbers, timber to the value of $827,337 was used in Canada during 1910 for mining purposes.

This total is made up of 52,848,000 linear feet of round timber, worth $523,339, and 22,305,000 board feet of sawn timber, which cost $303,998.

The various species of woods used by mining industries are chosen, not because of their superior technical qualities, but because of their cheapness, suitable size and accessibility. Thus, Douglas fir is the most-used mining timber because it grows in the province where most of the mining is done, and is easily obtained. When this is understood it is easily seen why the use of each species is confined to one province. British Columbia used all the Douglas fir; Nova Scotia used practically all the spruce, balsam, hemlock, birch, beech, and maple; Alberta used almost all the jack pine and poplar.

Round Timber.

Table 1 shows by provinces the quantity and value of the round timber used by mines in Canada during 1910.

An Albertan Fire—how too much good timber disappears

of this amount was four to six-inch Douglas fir, used by two of Canada's largest coal companies for lagging.

Nova Scotia, using 30 per cent. of the Canadian consumption, is second in importance; 15,653,000 linear feet were used at a cost of $168,142. The price this averages $10.74 per thousand linear feet, and is, after that current in British Columbia, the lowest price. Spruce five inches in diameter formed a great proportion of this province's consumption.

TABLE 1.

Round Mining Timber, 1910, by Provinces; Quantity, Value, Average Cost, and Per Cent. Distribution.

Province or District.	Quantity M linear ft.	Per cent. Distribution.	Value	Av. cost per M linear ft.
British Columbia	29,047	55.0	$203,597	$ 7.01
Nova Scotia	15,653	29.5	168,142	10.74
Alberta	7,484	14.1	132,900	17.75
Ontario	549	1.2	14,724	26.83
Saskatchewan	105	.2	3,597	34.25
Yukon	10	*	379	37.90
Canada	52,848	100.	$523,339	$ 9.90

*Less than one-tenth of one per cent.

The mines of Canada used, in 1910, 52,848,000 linear feet of round timber, which cost $523,339. This is an average cost of $9.90 per thousand.

British Columbia alone used 55 per cent. of this consumption, i.e., 29,047,000 linear feet, at an average cost of $7.01 per thousand. This is a lower price for round timber than in any other province, the smallness of price being due to the fact that nearly 20,000,000 feet

Norway Pine Typical of Nipissing District.

Alberta used 7,484,000 linear feet, or 14 per cent. of the total. This quantity cost an average of $17.75 per thousand. Over 70 per cent. of this was small lodge-pole pine. Spruce made up nearly 25 per cent. and the balance was mostly Douglas fir.

The foregoing three provinces, namely, British Columbia, Nova Scotia, and Alberta, contain all the important coal mines in Canada, and consume 98.6 per cent. of the timber used in mining. The remaining 1½ per cent. was used in Ontario for ore-mining, and in Saskatchewan and Yukon for small coal mines supplying local demands.

Ontario mines used 549,000 linear feet, at an average cost of $26.83 per thousand. Nearly one-half of this was spruce five to seven inches in diameter; one third was pine of small diameters. The remaining one sixth was tamarack and timber of unspecified species. The mines in Ontario use, so far, a very small amount of timber per mine as compared with the large mines of British Columbia. Most of the Ontario mines are small and shallow, and are excavated in the solid rock so that little timber is required for protection. Moreover, a great number of the mining companies incorporated in this province have not advanced sufficient far in their operations to require any timber.

Saskatchewan has a very small number of coal companies, only one of which sells to the public; 105,000 linear feet were used in this province, and cost, on

erage, $34.25 per thousand. The high price of this nber is due to transportation charges, either from e spruce and tamarack belt of northern Saskatchen or from the Rocky Mountains.

Ten thousand linear feet of spruce were used by the al and gold mining companies of the Yukon territory an average cost of $37.90 per thousand. This is all tive wood and the high cost of this amount is due expensive labour. The small quantity of timber ported from Yukon is explained by the small number deep mines. Mining operations do not extend far low the surface, and therefore there is no great nessity for timbering.

Table 2 shows by relative importance of species, the und timber used in Canada in 1910.

and British Columbia, and comprises 90 per cent. of the so-called "jack pine" listed.

Hemlock, which was the cheapest species of lumber produced in Canada in 1909, formed only 2.3 per cent. of the total consumption of mining timbers in 1910. Nova Scotia used all the hemlock, 1,172,000 feet, at an average cost of $13.39 per thousand. Very little hemlock grows in the mining districts of Canada.

The above five species (Douglas fir, spruce, jack pine, balsam, and hemlock), of which jack pine was the most expensive, were the important woods used by the mining industries, forming over 96 per cent. of the total quantity of the 12 species reported.

Tamarack or larch was used to the extent of 893,000 feet, and cost $15,029. This is an average cost of $16.72 per thousand linear feet, the highest price paid

TABLE 2

ound Mining Timber, 1910, by Species; Quantity, Value, Per Cent. Distribution and Average Cost per Thousand Linear Feet.

Species.	Quantity M linear ft.	Per cent. Distribution.	Value	Av. cost per M linear ft.
Douglas fir	28,268	53.8	$198,776	$ 7.03
Spruce	14,417	27.5	179,734	12.46
‡Jack pine	4,455	8.5	66,751	14.96
Balsam	2,170	4.1	21,215	9.78
Hemlock	1,172	2.3	15,691	13.39
Tamarack or Larch	893	1.7	15,029	16.72
Pine	720	1.4	10,234	14.21
Birch	326	.6	4,311	13.22
Poplar	54	.1	848	15.70
Cedar	23	†	1,107	48.13
Maple	1	†	11	11.00
Beech	1	†	11	11.00
*Total	52,848	100.	$523,339	$ 9.90

*The total includes a small amount of timber not identified by species.
‡Includes jack pine and lodgepole pine.
†Less than one-tenth of one per cent.

The mines of Canada reported the use of twelve ecies of wood in their mining operations.

Douglas fir alone was used to the extent of 53.8 r cent. of the total represented by the twelve species. ,268,000 linear feet of fir was used, which cost $198,-6. This is an average of $7.03 per thousand, which the smallest price paid for any species. Fir is a ry popular wood for mining purposes, particularly British Columbia, on account of its accessibility and rength.

Spruce stands second in importance and contributed er one-quarter of the total; 14,417,000 linear feet ere used at a cost of $179,734. This is an average cost $12.46 per thousand. The great quantity of spruce due to its occurrence in Nova Scotia, where it is sed by most of the coal mines. Although in amount early twice as much fir was used as spruce, in value r was worth only $19,042 more than spruce; this is ue to the difference of $5.37 per thousand feet in the st of spruce over that of fir.

Jack pine was the third important species; 4,455,000 et were used, at a cost of $66,751. This is an averge cost of $14.98 per thousand. The entire quantity f jack pine mining timber was used in Alberta. Two ecies of pine are included under jack pine. The ne is the true jack pine, (Pinus Banksiana), and the ther is lodge-pole pine (Pinus Murrayana). Lodgeole pine occurs extensively on the slopes of Alberta

Typical Jack Pine Country

for any mining timber except cedar. Over 700,000 feet of this was used in British Columbia; 158,000 feet was used in Alberta, and the remainder was about equally divided between Saskatchewan and Ontario. Larch is a splendid mining timber, but its use is limited by its scarcity.

Five-sevenths of all the pine used was consumed in British Columbia coal mines. Ontario ore mines used nearly all the balance. The pine used in British Columbia is yellow pine and western white pine. The total pine used was 720,000 feet, and cost $14.21 per thousand linear feet. Small quantities of red and white pine were used in Ontario.

Birch formed less than one per cent. of the total; 326,000 feet were used in all, costing $4,311. This is an average of $13.22 per thousand linear feet. All the birch mining timbers were used in Nova Scotia.

All the poplar used, 54,000 feet, at $15.70 per thousand, was used in Alberta. Poplar is cheap and accessible, but is not sufficiently durable for use in mines.

One thousand feet each of maple and beech were used in Nova Scotia at $11 per thousand.

There were also used 348,000 feet of timber, the kind of which was not specified. It came principally from the provinces of Ontario and Nova Scotia, and averaged in price $27.62 per thousand.

In table 3 is given the quantity, total cost, and average cost of the round mining timbers used in Canada, 1910, by diameter-classes and species.

There were used 1,835,000 linear feet over ten inches in diameter. This timber cost, on an average, $37.62 per thousand, and included the best quality of timber used in the mining industry. These large-sized timbers are used for heavy props and in gangways. For such purposes timbers are used up to three feet in diameter.

In comparing the prices of different species in the same class, consideration should be given to the fact that the diameter varies a great deal within each class.

Of the Douglas fir used in the mining industry, 411,000 linear feet was less than five inches in diameter and cost only $2.33 per thousand. The timber used under five inches diameter was practically all Douglas fir and was used by the large coal companies of British Columbia. Of timber varying from five to nine inches in diameter, 10,110,000 linear feet were used, which cost $12.92 per thousand feet. Fir also stands second in importance in the largest diameter class; 747,000 feet were used, which cost, on an average, $36.92 per thousand linear feet.

Spruce was used to the extent of 445,000 feet in the class under five inches in diameter. This species was used more in the five-to-nine-inch class than any other species, the amount being 13,116,000 feet. The 856,000 feet over ten inches in diameter was all used in Alberta. Spruce of the first diameter-class cost $8.35 per thousand, while fir of this size cost only $2.33 in British Columbia. This apparent inconsistency is due

TABLE 3.

Round Mining Timbers, 1910, by Diameter-Classes and Species: Total Quantity, Total Cost, and Average Cost.

Species	Class 1—Under 5 In.			Class 2—5 In. to 9 In.			Class 3—10 In. and Over.		
	Quantity M linear ft.	Value	Average Cost.	Quantity M linear ft.	Value.	Average Cost.	Quantity M linear ft.	Value	Average Cost.
Douglas fir	17,411	$40,583	$ 2.33	10,110	$130,617	$12.92	747	$27,576	$36.9

*Total	19,046	$50,765	$ 2.66	31,967	$403,171	$12.63	1,835	$69,403	$37.8

*Includes a small amount of timber not identified by species.

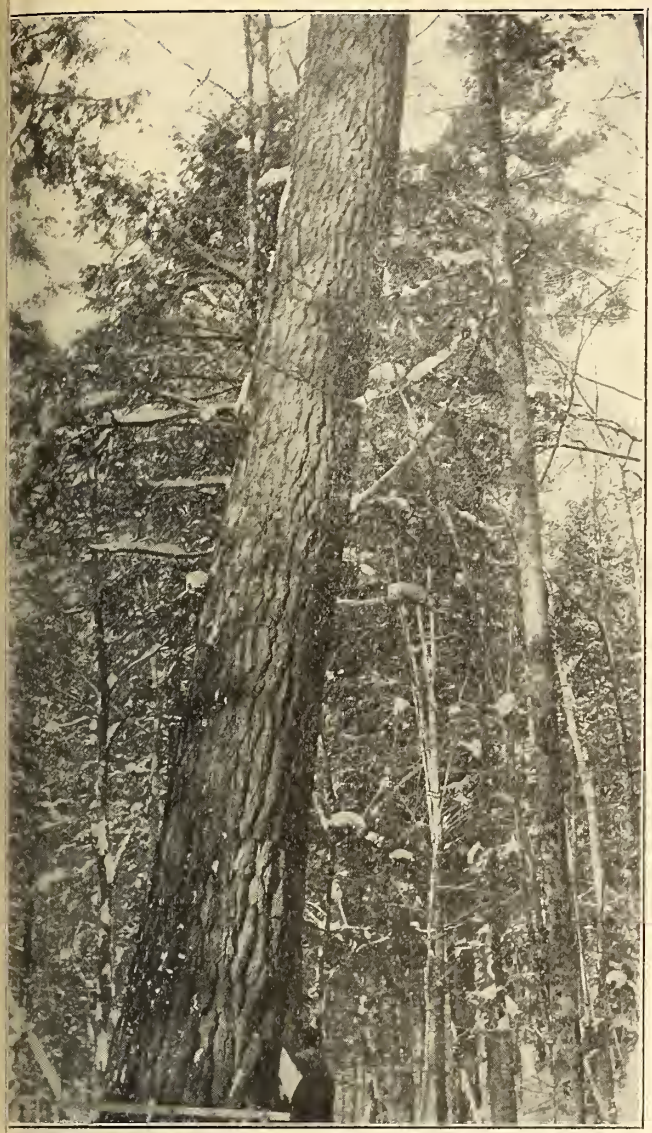
Of the 52,848,000 linear feet of round timber used in Canada during 1910, 31,967,000 feet were from 5 to 9 inches in diameter. Timber of this size cost, on an average, $12.63 per thousand, and was used for various purposes; 5 to 6 inch timber was used for caps 2 to 10 feet long, and for ties, 6 to 8 inch timber for long caps, and 12 to 16 foot booms, 5 to 9 inch material for props. In some mines, where the seam was narrow, four inch timber was used for props.

The class "under 5 inches in diameter" includes 19,046,000 feet, or over one-third of the total consumption. This cost on an average only $2.66 per thousand linear feet. It is used mainly for pinning and lagging. For pinning it is used in short lengths; for lagging it is used in lengths varying from eight to twelve feet.

to the fact that the spruce was used for props and the fir for lagging. The large spruce was all used in Alberta and cost $31.80 per thousand, less than the cost of big timbers in any other province.

Jack pine was important mainly in the second diameter class; 3,216,000 linear feet of this dimension were used in Alberta, costing $17.25 per thousand. To a small extent this species was also used in the third diameter class, and cost $61.60 per thousand. 1,156,000 feet of jack pine under five inches in diameter was used in Alberta, and cost $5.30 per thousand, making it next to Douglas fir in cheapness in this class.

The use of balsam was confined to the second diameter class and consisted of 2,170,000 linear feet at an average of $9.77 per thousand. Balsam appears as the cheapest species in this class, because it was



White Pine

Hemlock

e-inch timber used by a Nova Scotia company. It i a weaker and less durable wood than spruce or hem- k, and is worth less for mining purposes.

Hemlock was used only in two classes. In the sec- d diameter class 1,155,000 feet were used, costing 2.23 per thousand. In British Columbia 17,000 feet ed ranged from 10 to 36 inches in diameter. These l ge-sized timbers made the average cost $92.30 per t usand linear feet, the highest price paid for mine nbers.

Of tamarack or larch, 801,000 feet, five to nine inches i diameter, was used throughout the various pro- nces, and cost an average of $11.98 per thousand. l rch to the extent of 92,000 feet of 10 inches or more i diameter was used in British Columbia. It cost on e average $59.05 per thousand feet.

Pine, birch, and poplar were used in small quantity d practically all ranged from five to nine inches in ameter. The term "pine," as used in Table 3, in- ides western yellow pine, western white pine, red ne, and white pine; of this timber 96 per cent. be- nged to the first diameter class and four per cent. to e third diameter class.

In Alberta there were used 54,000 linear feet of plar five to six inches in diameter, which cost, on an erage, $15.70 per thousand.

Cedar was used only in British Columbia, and of the small cut of 23,000 feet used, two-thirds were in the medium class and one-third in the largest class. Cedar was used chiefly in the gold mines.

One thousand feet each of maple and beech were used in Nova Scotia; this was small-sized timber.

Less than one per cent. of the total amount of round mining timbers reported was of undetermined species; 317,000 feet were five to nine inches in diameter, and cost $29.90 per thousand. A very small amount, 31,000 feet, of ties were not specified, and cost $9.70 per thousand linear feet.

Sawn Timber.

Table 4 shows the quantity and value of sawn timber used in the mines of Canada during 1910, by provinces.

22,305,000 board feet of sawn timber were used, representing an expenditure of $303,998. This is an average of $13.63 per thousand. British Columbia used over 50 per cent. of this amount, of which the principal species was Douglas fir. The price of sawn lumber in British Columbia was only $12.28 per thousand, less than in any other province.

It is impossible to give correctly the species of sawn timber used in the various provinces, as the reports did not always state the species, but in most cases the

TABLE 4.

Sawn Mining Timber, 1910, by Provinces: Quantity, Value, Per Cent. Distribution, and Average Cost Per Thousand Ft. B.M

Province.	Quantity M Board ft.	Per cent. Distribution.	Value	Av. cost per M Board ft.
British Columbia	11,933	53.6	$146,510	$12.28
Alberta	5,569	25.1	77,114	13.85
Nova Scotia	3,282	14.8	45,281	13.80
Ontario	1,390	6.4	29,470	21.20
Yukon	105	*	5,025	47.85
Saskatchewan	26	*	598	23.00
Canada	22,305	100.	$303,998	$13.63

*Less than one-tenth of one per cent.

sawn timber would be the same species as the round timber.

Alberta used 25 per cent. of the total sawn timber, seven different species of wood being utilized.

Fifteen per cent. of the total consumption was used in Nova Scotia. Spruce was the principal species used in this province.

Ontario used about equal amounts of pine and spruce to make up the 1,390,000 board feet of sawn timber used in this province. Yukon and Saskatchewan used very small amounts. Yukon paid the highest average price for sawn timber, (namely, $47.85), most of which was spruce.

Table 5 shows by relative importance of species the amount and value of sawn timber used in Canadian mines during 1910.

Nova Scotia Spruce

Douglas fir was the most important species used f sawn timber, forming 56 per cent. of the total; 1 107,000 feet were used at an average cost of $10. per thousand, the smallest average price paid for sa mining timbers, exeept eedar. Spruce was used to t extent of 3,689,000 board feet, and formed over o fifth of the total consumption. Spruce was mueh mo expensive than fir, costing $18.33 per thousand. T two species just mentioned, namely, fir and spru alone formed over three-quarters of the total amou of the sawn timbers used. Tamaraek (lareh), pine, dar, jaek pine, hemlock, and birch were used in sm quantities and ranged in price from $9.90 per tho sand feet for eedar to $19.39 for pine; 48,000 feet oak were used, mostly by the metal mines of northe Ontario. The average cost of this timber was $89. per thousand feet; 436 feet of cypress at $110 p thousand was also used by one mine of this province.

Preservation.

The preservation of mine timbers by ehemical trea ment has not yet been adopted by the mining indu tries of Canada. In many loealities, however, the di tances required to transport mining timbers are b coming greater, poorer qualities of woods have to l used, and the annual cost of the upkeep of mine tim bering is becoming greater. In the United States muc has been done in the treatment of mine timbers, and has been proven that a treatment of creosote or zin chloride decreases the destruction due to decay, fi and insects. This increases the life of the timbers an decreases the annual cost of replacing mine timber Timber used in mines has, on the average, a shorte life than wood used for any other purpose. The su roundings in a mine are very conducive to rot, whic after a period of three to five years, eauses the timbe to break, crumble and become useless. Experiment have been conducted in United States mines with a ro of untreated and treated mine props alternatel placed. In one instance, after 18 months, every un treated stick was weakened by decay and broke while the treated props were sound and useful. Fro various practical experiments of this kind with di ferent species of wood, important results have been ob tained.

Douglas fir has an average of five years' life whe untreated. Treated, it lasts twelve years. Hemloek lasting as a natural wood five years, doubles its ter of life when treated, as does tamarack. Spruee is on of the species which decays quickest when untreated lasting only three years. If treated, it will last twelv years, thereby increasing its life 300 per eent. To sum up, wood preservation not only prolongs the life o

rable timbers, thus decreasing their annual consumption, but also permits the substitution of inferior species, whose use considerably reduces the drain upon the more desirable kinds.

Stock Value and Mine Value

Written for the Canadian Mining Journal by Alfred C. Lane.*

My object, or perhaps it would be fairer to say my nclusion, for I did not know the hole at which I ould come out when I started this investigation, is to ow that the value of a share of stock as given in the ictuations in the various stock exchanges is by no eans wholly that of the property which the stock presents. Thus it is not fair in assessing that prorty for purposes of taxation to suppose that it as the value that might be shown by measuring the ice of the shares of stock by the number of shares stock based on it. It has often been attempted to alue mining property for taxation in just this way, ut I think it can be clearly shown that such an efort would be very unjust as compared with adjacent roperty from which no shares have been issued.

Again, I may give some idea of what rate of return ay fairly be expected in mining investments. It is ot fair to expect a person who obtains a return which uncertain in amount and time to be satisfied with the ame return that he can obtain regularly and with no oss of principal or interest. A little study of mining tock values such as I propose to undertake will, I hink, show this, and we shall see that where a man is atisfied with 4 per cent. if the security is perfect and he returns regular, and he can at any time obtain is money to put into other forms of investment, he vill naturally and properly expect more, say about per cent., if he can not get his money back when e wants it; and if his money is to be tied up for an ndefinite time he will on the average expect about 0 per cent. I think it may also be said fairly that nining property should yield something like 7 per cent. to 10 per cent., even not allowing for extraordinary risks, but only for those that are inherent in the fluctuating prices of labour, supplies, and the metal produced. This, of course, has its bearing on questions of capitalization. I derive these conclusions by a study of past values and prices.

Five Elements in Fixing Price: Return, Stability, Marketability, Activity, Control.

One can not with much hope of success take a great mass of price fluctuations purely at random. If but two factors were involved it might be done by arranging the prices in order with regard to the variation of one factor and seeing how the other varied. But in fixing the price of a stock (which represents a share in a property) a number of factors play a part. While these can never be wholly separated, in some cases one is so much more important than another that it can largely be isolated. Then, by allowing for its effect we can little by little isolate the others. I tried to separate five factors in fixing price—five elements of value.

First, return, annually or regularly, in the shape of dividends or income.

Second, stability, respectively the remote increment or decrement of the principal. While this is not theoretically separable from the other, when the dividend or annual income is irregular, it is particularly important for us to consider it separately, as it and the values found are to be handled in a very different fashion.

Third, marketability, that is, the readiness with which a security may be sold for the money paid for it.

*Professor of Geology, Tufts College, Boston, Mass.

Fourth, activity, that is the range of fluctuations in price.

Fifth, control, or the value of the voting privileges attached to the stock.

(1) Return, the first element, is the fairly regular net return yielded by way of interest or dividend. The word "net" is added to remind us that if one security is subject, or liable to be subject, to taxation, the amount of tax or a part thereof proportional to the risk of the tax being collected must be deducted. This first factor of return is almost the only element of value to be considered by trustees of estates in considering securities of unquestioned value, and is by far the most important element of value in good bonds and mortgages.

Their value, however, is also affected by their marketability. To get this value as pure as possible, cases should be taken where the question of ready marketability did not come in. An ideal case, perhaps, would be a first-rate mortgage on property worth very much more than its value in the hands of a man of ample means known locally to be prompt and able to pay all obligations. This might be perfectly secure to any one knowing the facts but might not be readily marketable because of the investigation needed to convince a purchaser of these facts. In such cases as English consols, fluctuations in price and hence in interest take place which depend in part at least upon the prospect in the near future of a greater or less demand for consols and the possibility of buying the same at a less price or selling them at a higher.

(2) This suggests the second factor. The second factor, stability, is taken to cover the prospect of permanence or of increase or decrease in the value of the principal. This is the main element of value involved in speculation in any improved city lots and must be a large element in fixing the price of any stocks which do not pay dividends.

(3) The third element of value is that of ready marketability. The enlarged market means a higher price. If a certain class of securities is made a legal investment for savings banks or trustees, it at once increases their value. The capacity to turn the investment promptly into money so as to take advantage of some opportunity to reinvest or to pay debts as they come in, is worth something. Insurance companies and many other corporations must carry a certain proportion of their capital in securities of this class. This value is illustrated and to some extent measured by the difference in interest which will be paid for call money and for time loans. The man who lends money on call at a lower rate of interest than he could get for a time loan does so because he values the privilege of being able to get it back again at any time he sees a chance to make an especially good investment. If the rate for call money is about 2½ per cent. and for time loans about 3¼ per cent., an addition to value of a stock of 30 per cent. or more would be a comparable amount.

(4) A fourth element is the value of a stock as a medium of exchange or as an implement of organized speculation. Not only are stocks recognized to be desirable because they have a ready market, but to some people activity, that is to say, a continued play of values up and down, is an attractive feature. Though a ready market is made very largely by the activity of a stock as a means of speculation and the marketability and activity values are interwoven, yet the fundamental idea behind them is not the same and the fundamental motive is very different. In the one case the value is enhanced by the power to get mon back at short notice without fluctuation. On the oth hand. the value as the medium for speculation is e hanced by the very fact that a stock does fluctuate.

In the proposed consolidation of the Calumet a Hecla and many of the smaller Michigan copper m ing companies, much of the complaint of the broke and holders of the small companies was not at t value set upon their stocks as measured by any pr ent or definitely ascertained prospective returns, b at the fact that they would be obliged to change active for an inactive stock with a loss of speculati possibilities. I shall later show how a definite, n merical statement of this loss (?) can be given. I the activity value, then, is meant a value depende upon the hope to make a profit by change in t value of stock without regard to whether this chan is up or down.

It is hardly conceivable that this value should exi without some other element of value. It exists in i simplest condition in a poker chip and may well called the poker chip value; and while it does not o dinarily exist apart from the value of the stock other ways, yet one can to some degree isolate it as factor in price or value.

(5) The fifth element of value may inhere in t voting privileges that a stock carries, and may reside i a particular certificate of stock or a particular nun ber of shares of stock. It may not vary with t value of the property as a whole, but rather with t control of the whole property that it gives. We I to go out of the field to which I propose to confi myself, the famous struggle for the control of t Union Pacific or the quoted value of the Equitabl Life Insurance Company paying but 7 per cent., bu carrying the control of that company, might be cite Another illustration is that Alexander Agassiz wa offered $1,000 a share for his interest in the Calume and Hecla carrying with it the control of the property Upon his reply that whatever was offered him mus be made to every other stockholder, the matter wa dropped.* One can compute in such a case, roughl speaking, the value of this control factor. The sellin price of a small quantity of Calumet and Hecla withi a year before and after was between $600 and $800, an as will be seen, $600 was not so far from the value o the property on other grounds, so that the additiona control value was something like $300 to $400.

Now, while this last element becomes conspicuou in such illustrations as those cited, it remains to b seen if it exists at all times to a greater or less degree and can be traced in the fluctuation of a stock. It i one of the elements that make it hard to assess a pro perty fairly on stock market basis or to tax the own ers of such stock on the basis of single sales. There never was a time when all the stockholders of the Calumet and Hecla Mining Company could get $1,000 for their stock nor will any one compute any such value as 100,000 x $1,000 for that mine.

Now I plan to find the value of organized specula tion by finding first the yield from securities which have not such a ready market as organized specula tion affords and then compare the yield from listed se curities as similar as possible. The reduction in yield will measure that part of the value which is due to

*Editor's Note:—The action of Mr. James Ross in stipulating that all shareholders of the Dominion Coal Co. should be paid at the same rate as was offered for his shares furnishes a parallel Canadian instance.

marketability, or due to activity or to conditions other than the return either regularly or by appreciation at the end of a period of years.

I find that some people object to the idea that a stock exchange can be valuable by reducing income yield; but it seems to me clear that the activity of stock exchanges and organized speculation can not increase the income yield in any fashion. If they can make the stock with a given yield otherwise more desirable—if listing adds to the value of the stock—they will raise the price and thereby reduce the yield of the stock. It does not, however, follow that it will reduce the yield to the holder. The man who must have a certain sum of money at short notice, if he has no place where he can readily market his securities, might have to keep them in an old stocking and get no return, or in a savings bank and get 3 per cent. Thus the yield on the security in relation to its price or value may be reduced and yet the income to the purchaser may be better than he could otherwise get, since the security would not be otherwise available to him.

Investigation Confined to Michigan Securities.

In order to get rid of the effects of the different laws I shall confine this study mainly to Michigan securities with a particular view to the listed Michigan copper stocks. I am more familiar with them, and, moreover, Michigan laws enable one to obtain important facts not to be obtained elsewhere. Also, the age of the mines and the records of price are sufficiently long to enable one to study average fluctuations in a way in which it can be done for mining stocks in no other districts. Compared with the railroads, the elements of financial and political entanglements are reduced to a minimum. Finally, the recently proposed consolidation of a number of companies has made public in the papers many facts which are of help in our inquiry.

There is one element that I have found difficult to treat satisfactorily. That is the question of unenforced taxation laws upon the yield that stockholders can be fairly supposed to get. Were all stockholders residents of Michigan, that would be eliminated, since property is taxed only once; but the Michigan copper stocks are largely held in Boston and other places where there is a pretence of double taxation. For instance, a stockholder having a residence in Michigan can not be taxed on his copper stock, but if he should move to Massachusetts he would theoretically be taxed at a rate which around Boston would vary between 1 per cent. and 2½ per cent., or about a quarter of his income. This, however, is generally not collected from business men; but to some extent is collected from widows and orphans and their trustees. Consequently on the death of an owner of these stocks and the passing of the stocks into the hands of trustees it becomes at once of less income-bearing value. If thrown on the market by the trustees the value of the stock itself may be affected. If volume of "Lake buying" or Michigan buying is sufficient to determine the range of prices. this factor need not be considered, and it is a platitude of economics that a very small amount of buying added or subtracted may control the prices. Judging from newspaper comments "Lake buying" has a distinct effect upon Boston stock exchange prices. It will be noted that very considerable mines like the Calumet and Arizona are controlled in this district. One can then compare the prices of copper mines and other securities open to the Michigan investor.

The same principle, namely, that the price is affected by the subtraction of even a small group who can find a more profitable investment open to them elsewhere, also applies in comparing these stocks with trust fund investments. If the same people did not purchase either there would be no possible connection in price. But some people do have investments in both classes of securities, so that a large disparity in prices between the two would tend to change their investments, and, even though the vast bulk of purchasers belong to different classes, the appreciable number who hold in common may be sufficient to produce a connection in price. The Michigan law compels a filing of lists of stockholders and the larger have been published in the papers. It is possible, therefore, to be sure that there are some common holders of the various stocks which are to be compared.

I propose to place in the body of the paper just enough figures to make clear the point of the argument, leaving to a series of notes (something like the old-fashioned excursus, which always used to delight me) details of figures and qualifications and answers to possible objections.

Return from Stable, Non-Marketable Stock 6.3 Per Cent.

The first question to which we shall address ourselves is to find the part of the value of a stock which is due merely to its income-producing power. In Michigan we get this as nearly pure as possible in mortgages, or in shares of building and loan association stock which are but the average result of such mortgages. The Northern Michigan Building and Loan Association, of Hancock, in the copper country, has been maturing shares which have yielded from 6 per cent. to 7 per cent. For instance, shares at $1 a month and 50 cents initiation fee mature at $102.50 in eleven years, making a compound interest rate of 6.3 per cent., or a paid up share of $80.50 yields $4 a year. This is close to the common "legal" rate of interest of 6 per cent. It will, of course, vary from community to community and from time to time, but during the past twenty years the national bank in Houghton, which is the principal banking town of the copper country, has been making time loans at 7 per cent. I assume, then, that a security yielding 6.3 per cent. a year and absolutely secure, or a group of securities which on the average will not depreciate or increase in value, should be worth $100. Any lower rate of yield would mean an increased value due to some other cause, and a higher yield would mean a decrease of value due to insecurity or irregularity of yield or some other cause.

Return from Stable, Marketable Shares 4.2 Per Cent.

Let us next look at equally secure stocks, which have the added advantage of marketability, to see how much lower rate of interest they yield. We find them best represented in such guaranteed Michigan railroad stocks as the Fort Wayne and Jackson, the Detroit, Hillsdale, and South Western; the Grand River Valley, and the Jackson, Lansing and Saginaw — guaranteed stocks of the New York Central system. Though the rate of interest varies from 3.5 per cent. to 5.5 per cent., the price was (December, 1910) so adjusted that the income return varied only from 4.07 to 4.34. They had fallen two to five points in a year, but never vary widely. In July, 1911, the yield had dropped to 4.03, as money was then very cheap in New York. The yield upon such stocks (4.2 per cent) may be taken as that which could be obtained from an investment

which is absolutely certain, in which no question of taxes could arise and which is readily marketable. The savings banks of the copper country also had been paying 4 per cent. on savings banks deposits. Theoretically those savings banks deposits are subject to taxation at a rate of nearly 3 per cent., which would leave a net yield to the owner of 1 per cent. I need not comment upon this. The law is obviously a farce.

Increase of Value 50 Per Cent. Due to Organized Speculation.

It follows that if 4.2 per cent. is the yield of stock combining marketability and security and 6 per cent. to 7 per cent. (say 6.3 per cent.), if the security is not so marketable, there is 52 per cent. difference in rate of income. This is due to an increase of 52 per cent. in the value of the listed stocks over what they would sell for were they on the same basis as the building and loan.

I presume some may challenge so large an increase of value as that, but there can be little difference of opinion as to the normal interest return of about 4 per cent. on a perfectly safe guaranteed marketable stock, and I could produce plenty of evidence of a return from 6 per cent. to 7 per cent. in Michigan on as safe securities not so readily marketable. Moreover, this is often the ratio of difference between "call" money and "time" money, which differ in just the same way.

Return from Unlisted, Unstable Securities 10 Per Cent.

The next question is that of the stability factor, the appreciation and depreciation of principal and its combination with other factors. It is to be expected that, on the whole, one would want and, on the average, receive rather more return for such investments than on a mortgage, where one must wait an uncertain time before getting his reward. I shall again measure the stability factor by its effect on the return. A difficulty arises in that individual transactions do not mean much since they are so much affected by individual circumstances that they throw little light on the question as to whether a man prefers one dollar or one chance in one thousand to have one hundred dollars — whether a bird in the hand is worth two in the bush or more or less, or whether in average speculative real estate investments the net average return is the same as on a mortgage and to the average American the fact that he has to take a chance is no disadvantage if only he stands to win as much as he stands to lose.

Land appreciation—St. Mary's Canal Mineral Land Company.—Can one, then, find any clue to the speculative value of land in Houghton county, that is, the income to be derived from its appreciation? I think one may obtain a rough idea from the profits of the old St. Mary's Canal Mineral Land Company — a corporation that existed from 1863 to 1900 and held large tracts of land sprinkled all over the Keweenaw Copper Range, having, when reorganized in 1901, something over 104,000 acres of land. There were only 20,000 shares, and it was always very closely held and (up to the last few years) was not listed and not readily marketable at a forced sale. Between 1863 and 1900 it paid in cash some $111 per share beside certain shares in stock, which seem to have been enough to raise the total value to $135 per share. This makes an average return of $2.74 a share per annum for the 57 years, and during the years 1891 to 1896 it sold at from $27.75 to $35 per share. This was on a basis of about 10 per cent. return.

At the end of this period very valuable mines we developed on an adjacent property belonging to th Copper Range Company, and the company was reo ganized and adopted the policy of holding rather tha distributing many of the shares issued for land. was also listed but we can see what the results woul have been if it had continued its previous policy fro its annual reports.

It seems, therefore, likely that speculative inves ments in mineral lands may net an average interes of 10 per cent., for though it must be remembered tha the lands of the St. Mary's Company were shrewdl picked in early days and that to some extent perhap the lands sold may be the cream—on the map the appear scattered almost at random. Other facts, how ever, in the sale of tax titles and individual purchase are known to us which suggest that the speculativ value of random mineral copper lands represented b unlisted companies is not far from $25 an acre, a which price it may be expected to yield 10 per cent.

This simply shows that in a field of unlisted invest ments where quick returns are out of the question, un certainty is not more attractive than certainty, and o the average, business men do not buy and hold minera lands on speculation unless they can average to get a good deal more than bank discount or mortgage loa interest for it—a not surprising conclusion. A curious fact is that the ratio which appears to be as 10 per cent to 6.3 per cent. is not so very far from the traditiona ratio of the bird in the hand to the bird in the bush.

Probable Return from Good Unlisted Copper Mines About 10 Per Cent.

To find the value or interest return of a copper min apart from its marketability is not easy, since none o the Michigan copper mines seems to be worked except by corporations which, if they have amounted to any thing, have rarely ever had their shares listed.

It might be expected that the returns would be some thing like those of the Mineral Land Company since the very same men were interested, and that men would not put their money into copper mining with the uncertainties due to accidents like fires and caving and fluctuation in the price of copper, to say nothing of the uncertainties of the deposit itself, unless they could get as much as they get in mineral land speculation and more than bank discount or mortgage interest.

This inference is confirmed by the estimates of engineers. In the collection of articles by various engineers published as the 'Economics of Mining" (page 225) we find Robert Stevenson referring to gold mines as follows: "Having found all these, the extra capital should be subtracted from the gross profit, and the balance capitalized, so as to yield 10 per cent. per annum during the time necessary for exhaustion, and at the same time redeem the principal." He also cites Mr. Curle to the same effect. Other pertinent remarks will be found in this book, especially on page 79 where the theory is criticized that a mine should have 60 per cent. of its market value represented by net profit on ore and must yield 10 per cent. on the investment price.

From the form of the tables and the examples used by Hoskold's "Engineering and Valuing Assistant," it seems that at least in England in coal mine leases, etc., which are rarely public propositions, it has been customary to allow 10 per cent. to 20 per cent. interest beside a fund to replace the capital at a much lower rate of interest up to 4 per cent. These lower rates obviously represent the absolute security rate of interest, and the fact that his Table X runs up to 20

per cent. suggests that mining interest up to that figure is a practical proposition. This appears also from the examples and the tone of various comments in the text.

Hoskold stoutly maintains that one rate of interest should be assumed on the money and another and lower rate of compound interest on that part of the return which is laid aside to replace the principal. This would, indeed, be true in case there were an actual sinking fund, that is, amortization fund, built up and invested at savings bank rates to replace the capital at the end of the life of the mine. But if one is going to discuss what rate of interest is received in mine investments it seems better to discount payments, actually received or expected, by that rate of compound interest which may fairly be expected on mining investments in general.

Hoover, however, in his "Principles of Mining" (page 43) says that the mining business is "one where 7 per cent. above provision for capital return is an absolute minimum return of capital."

In view of the fact that most mines are listed this is not inconsistent with the other statements. It seems pretty clear that a return of over 7 per cent. and probably at least 10 per cent. (to which must be added something in case the rate of production is such as to exhaust the mine within a period when its exhaustion is of importance) is expected and received.

With regard to exhaustion being of importance if one assumes such a relatively high rate of interest on money as 10 per cent., then the present worth of a dollar to be paid after 35 years is but three cents. Consequently if one assumes that money invested in mining is going to earn such high rates of interest the importance of final replacement of capital becomes relatively small as soon as the mine has a generation lifetime.

(To be Continued.)

PERSONAL AND GENERAL.

Mr. R. W. Leonard was in Toronto on his way to Cobalt on October 23rd.

Dr. J. A. L. Henderson, of London, England, who is developing the oil and gas fields near Moncton, N.B., was in Toronto on October 24th.

Mr. James McEvoy spent several months this summer on Groundhog Mountain, near Hazelton, opening up coal measures for a Toronto syndicate. He will probably spend the winter in Toronto.

Mr. J. T. Stirling, of Edmonton, Alberta, provincial inspector of mines, recently visited the Crow's Nest Pass Coal Company's colliery at Coal Creek, near Fernie, B.C.

Mr. Francis Aspinall, formerly engaged in coal mining in the Crow's Nest Pass district of British Columbia, has been appointed inspector of mines in the Crow's Nest district of Alberta, with headquarters at Macleod.

Mr. E. Jacobs, of Victoria, B.C., has been visiting coal mines situated along the Crow's Nest Railway, from Fernie, B.C., to Lethbridge, Alberta, obtaining information for a series of descriptive articles on the mines visited.

Mr. Robert H. Morris, late superintendent for the Mexican Coal and Coke Company, is now superintendent for the Jasper Park Collieries, Limited, which is opening coal mines at Pochahontas, Alberta, distant 205 miles west of Edmonton, along the line of the Grand Trunk Pacific Railway. The G.T.P. is now taking coal from one of this company's mines.

Mr. Lewis Stockett, of Hosmer, Crow's Nest Pass district, B.C., chairman of the Western Coal Operators' Association, was in Lethbridge, Alberta, on October 13th and 14th, in connection with a renewal of negotiations with the officers of District No. 18, United Mine Workers of America, relative to a resumption of work by the coal mine employees, who have been on strike since April 1st, last.

Mr. A. J. McNab, who for the last three years has been superintendent of the Consolidated Mining and Smelting Company of Canada, Limited's, lead and copper smelting works at Trail, B.C., recently resigned that position to join the metallurgical staff of the Mason Valley Mines Company, with smelting works in Nevada. Mr. Jules Labarthe, formerly manager of the Trail smelting works, is now general manager for the Mason Valley Company.

Mr. W. W. Leach, of the Geological Survey of Canada, having completed the season's field work in the Blairmore-Frank district, Alberta, where he has been investigating the geology of the country, is about to return to Ottawa. Mr. G. S. Malloch has been continuing this year the work in the Skeena district upon which Mr. Leach was engaged several years until his illness last winter.

Mr. Chas. Fergie, of Montreal, Que., was in the Lethbridge and Pincher Creek districts, Alberta, about the middle of October, visiting several coal mines being developed and equipped under his direction. Mr. Fergie acts in an advisory capacity for the Lethbridge Collieries, Limited, with colliery at Kipp, near Lethbridge; the Western Coal and Coke Company, Limited, which is opening a coal mine at Beaver Creek, about 14 miles southwest of Pincher, on the C. P. R. Company's Crow's Nest Railway; the St. Albert Collieries, Limited; and the Pacific Pass Coalfields, Limited, developing coal property situated along the line of the Grand Trunk Pacific Railway, about 160 miles west of Edmonton.

ENGINEER'S REPORT ON ST. ANTHONY MINE.

[Editor's Note.—The following interim report by J. C. Houston is of interest as supplementing the description reproduced elsewhere in these columns.]

Dear Sirs,—As per your request, I beg to herewith hand you a supplementary report on the present physical condition and the possibilities as indicated by the last few months' work on the St. Anthony property.

On the main vein to the south we have driven for a distance of 160 feet past the old No. 3 shaft (on the 100-foot level), or to directly under the edge of Couture Lake. It was not thought advisable to drive under the lake at this level, as there would not be enough ore available above the level to warrant the work. At the point where work was discontinued the vein is about 30 feet wide, with three separate bodies of 8 feet, 5 feet, and 3 feet in width, respectively. For the full 160 feet, which we drove on the first or easterly body, it is the full width of the drive and in places more than that, and of $12 to $15 in value.

We are at present breaking out a stope to the south of No. 3 shaft, and have to take 10 to 12 feet in places to get all the ore. Sampling through the mill shows this to be from $12 to $14 ore.

Further north, beyond the north end of the open cut, on the 100-foot level, we have cut into a lens of ore, in the west wall of the drive, which had been over-

looked by the former operators. We are driving back south on this, and find that it is paralleling the small vein on which the old operators drove through on. It is about 6 to 8 feet wide, of $14 ore. We have crosscut into it in the wall of the open cut about 20 feet above the level, and find it 10 feet wide, of excellent ore, which will probably carry through to the surface or near there. This fills in the gap which my first sampling showed very low grade, the main vein having been left in the wall. I think it will be found that the main vein will carry a good width of good mill ore all the way to the main shaft, and probably 300 feet beyond to the north. This vein at the furthest point south on the 100-foot level, where work was suspended, is larger and stronger than at any other point opened, and should continue for several hundred feet further under Couture Lake. This can be opened up on the second and succeeding levels.

cut it, on the 100-foot level from the main shaft.

Between it and the main vein there is a small vei which we have partly stripped. It is about three fe wide, and shows some free gold. This is probably th outcrop of the vein that we started the No. 2 winze o at the 100-foot level. Both these veins give grea promise of a large tonnage of good mill ore. The su face assays, showing from $3 to $30 per ton, and th underground samples on the small vein even bette

The really important development of the summe was the discovery of the new No. 4 vein, which wa uncovered about 180 feet to the west of, and paralle ing, the main vein on the south end. We have not ha time to strip it nor has there been a shot put in it ye It shows rich pannings in the surface dirt at any poin along the outcrop, it being not uncommon to get a much as $3 worth of gold in a single pan. We ar driving a crosscut from the main vein at the 100-fo

The No. 2 winze was put down 60 feet, and a crosscut started to get under the main shaft. This crosscut is in about 35 feet and has about 15 feet more to go. As soon as the station at this level is cut and the shaft raised through to the first level a crosscut will be run west to intersect the main vein, which dips in that direction.

To the north of the main shaft, on the first level, some stoping has been done, but as ore still keeps showing on the east or footwall side, notwithstanding that the stope is 20 feet wide in places, it was thought better to crosscut into this wall to see how wide the ore body really is before starting to timber. This ore on sampling through the mill, runs from $16 to $18. This work, as well as a lot of other exploration work that has been planned, will have to wait until we have the power necessary to carry it through.

The big No. 2 vein to the east has not had any work done on it yet. We still have about 25 or 30 feet further to go in the crosscut, which we are driving to level at the south end to cut this vein. It is in now about 80 feet and has about 90 feet more to go. Small stringers were encountered at different points in this crosscut, some showing visible gold, and all giving good assay values.

The close proximity of all these veins (all being within a width of 400 feet), with the main vein in the centre, makes an ideal proposition for cheap and quick development.

The location of the property, lying, as it does, between Sturgeon and Couture Lakes, and within nine miles of the main line of the G.T.P., gives it natural advantages possessed by no other property in Ontario.

The mill sampling bears out the statements made in my former report, that we have large quantities of $10 to $15 ore, enough to keep a mill at work for many years.

Awaiting your further commands, I remain,

Yours very truly,

(Sgd.) J. C. HOUSTON.

The Vipond Mine of the Porcupine Gold Mines Co.

Written for the CANADIAN MINING JOURNAL by H. P. DAVIS.

The Porcupine Gold Mines Company was organized under the laws of Delaware in March, 1910, and at the date of organization took over the North and South Vipond properties, two mining claims in Mountjoy Township, and, through the ownership of the Ridgeley Porcupine Mines Company, acquired a three-fourths interest in the Atchison-McDougal claims. Since the organization the Porcupine Gold Mines Co. has purchased the Airth claims, and has taken a working option on the South Thompson property. The company at the present time owns or controls the following properties:

North Vipond, s.e. quarter or south half Lot 10, Con. 11, Tisdale ..... 40 acres
South Vipond, n.e. quarter of N. Lot 10, Con. 1, Tisdale ..... 40 acres
Airth, n.w. quarter of north half, Lot 9, Con. 1, Tisdale ..... 40 acres
South Thompson, n.w. quarter of north half, Lot 10, Con. 1, Tisdale ..... 40 acres
(Held under option agreement.)
Three-fourths interest in Atchison-McDougal group of six claims in Lot 5, Con. 11, Tisdale ..... 240 acres
Mining Claim No. 15443, Mountjoy Township 40 acres
Mining Claim No. 15444, Mountjoy Township 40 acres

Total ..... 480 acres

The Vipond Group.

This group includes the North and South Vipond, the Airth, and the South Thompson, 4 claims of 40 acres each, making a compact block of 160 acres, located southeast of the properties of the Hollinger Mines. The geological formation is of the Keewatin series. The claims referred to lie in the amygdaloidal basalts immediately south of the contact of the quartz porphyry of the Pearl Lake area.

The intrusion of the quartz porphyry has resulted in a very extensive fissuring in this area. The general course of the fissuring is northeast and southwest. The veins in this immediate vicinity show great resistance in strike, and are generally well defined with continuous ore shoots, and evenly distributed gold values.

In April, 1910, the Porcupine Gold Mines Company started development work on the Vipond claims, and by surface trenching and stripping exposed numerous quartz veins. Underground development work has been confined to veins Nos. 2 and 3. These veins have a general trend of northeast and southwest, and are approximately 100 feet apart.

Vein No. 2, which has been uncovered on the surface

Outcrop No. 3 Vein

for 600 feet, shows a varying width of from 4 to 6 feet of quartz, mineralized schist, and ferro-dolomite. The outcrop of this vein was sampled in June, 1910 Channel samples show an average value of approximately $30 to the ton. These results have been repeatedly checked and verified by independent engineers.

On No. 3 vein sampling of the outcrop shows that the quartz for an average width of 12 inches assays $83.45 to the ton. At various points along the vein assays have shown values of from $8 to $16 for a width of 8 feet. In these samples the richer ore shoot was not included.

A working shaft has been sunk to the 100-foot level midway between veins Nos. 2 and 3, and at this level a crosscut driven from the shaft to vein No. 2 and drifts driven on No. 2 vein, for a total distance of 320 feet.

The ore from these drifts for an average width of 42 inches assayed $23.10 to the ton. These results were

Test Pit No. 2 Vein

confirmed and checked by the operations of a one-stamp Nissen mill.

No. 2 vein has been proven on the surface for 600 feet, and at the 100-foot level for 320 feet.

At a point 120 feet west of the shaft a crosscut has been driven from No. 2 vein 110 feet to vein No. 3. The crosscut reached the vein just before the Porcupine fire destroyed the surface plant of the company. Where

ncountered, the No. 3 vein shows 15 feet of ore which verages, after careful and repeated sampling, $11.20 o the ton.

The south wall has not yet been reached, and as the drill holes for the last round of shots fired showed quartz nd sulphides, additional width is assured.

The working shaft has been sunk to a depth of 200 feet, at the 200-foot level a station has been cut. When the timbering is completed, crosscuts will be driven north to the No. 2 vein, and south to the No. 3 vein. Drifts will be run both east and west on each of these veins.

Plant.

At a meeting of the directors of the company, held in New York, on Tuesday, October 3rd, it was announced that $125,000 had been provided for treasury purposes, and that orders had been placed for a mill with the capacity of 100 tons per day. In addition to the new mill, a complete mining plant, including a 10-drill compressor, boilers, a 30 horse power hoist, and drills, is being installed.

It is expected that the mill will be in operation by February 15th. The small test mill destroyed by fire, which operated under difficulties owing to the lack of sufficient motive power, earned sufficient money to carry on development work on the property. The new mill will be operated by electric power furnished by the Porcupine Power Company.

The plant and mill have been so designed that the capacity can be increased as warranted by mine development.

The development work at the 100-foot level has already blocked out a considerable tonnage of high grade milling ore in the No. 2 vein. As the limits of the ore shoot have not yet been reached, further development will naturally increase the reserves above this level.

The crosscut in the No. 3 vein at the 100-foot level has indicated a large tonnage of pay ore.

On the completion of the compressor plant in December, the development work will be carried on at the rate of 500 feet a month both on the 100 and 200-foot levels. Crosscuts will have been run from the station at the 200-foot level to the No. 2 and No. 3 veins, and drifting will be started both east and west on both veins. Development work, including upraises and a small amount of stoping, will amply supply the mill.

The main shaft will be continued to the 300-foot level.

For the present, development work will be confined to the known ore bodies, and every effort will be made to increase the ore reserves.

IMPORTANT COAL MINING DEVELOPMENTS.

Although production of coal from the Crow's Nest Pass Coal Company's mines in southeast Kootenay has not yet been practicable during the last six months, owing to the miners and other employees having been on strike, the management has not been idle, for attention has been directed to the examination of the surface of parts of the company's property where the general manager, Mr. W. R. Wilson, thought it likely there would be found seams of coal not previously worked, or where some of those already known might be opened to greater advantage. As a result, the development of several practically new seams is in progress, with promise of them, in due course, becoming productive of coal of excellent grade and in considerable quantity. Some of these are at Coal Creek colliery and others at Carbonade, on Morrison Creek.

On the south side of Coal Creek four such seams are being opened. All of these are above No. 2, which has long been known as the best seam from which coal has been mined at that colliery. These are severally known as No. 1, A, B, and C seams. Their respective heights above No. 2 seam, the entry to which is at tipple level, are as follows; No. 1, 80 feet; A, 200 feet; B, 340 feet; and C, about 500 feet. The coal opened in A, B, and C seams is of excellent coking quality, a full average working section having shown on analysis but 6 to 7 per cent. ash, while picked samples gave only 3 per cent. The C seam was found 11 years ago, when Mr. Wilson was formerly in charge of the property, but had not since been developed. A plan for the systematic opening of this seam is now being outlined. The coal in both C and A seams, so far as indicated by the work done on them to date, is quite equal in quality to that of No. 2 seam, already mentioned as having proved to be the best in the Coal Creek mines. A double-track, endless-rope tramway is being constructed from the level of the colliery tipple up past No. 1 to B seam. This will have a total length of 1,900 feet, and will serve for opening three of the new seams.

On the north side of Coal Creek, prospect tunnels are being driven for the purpose of also developing there A, B, and C seams, all lying above No. 1, which last seam has been extensively worked on that, though not on the other, side of the creek.

At Carbonade, on the south side of Morrissey Creek valley, the work done during recent months has been chiefly with the object of further proving a change in the structure of the coal found to have occurred where this development was commenced; also of prospecting three seams not previously worked in this part of the property. The outlook for this colliery is now regarded as more favourable than for some time past, for there appears to be good reason for hope that it will hereafter be practicable to ship from the Carbonade mines a considerable quantity of coal of good marketable quality. Only a few men are employed here at the present time, but it is expected that when labour conditions shall again be normal in the district, quite a number will be engaged in mining and shipping coal.

CONDITION OF TURTLE MOUNTAIN, ALBERTA.

The commission appointed by the Dominion Government to examine Turtle Mountain, near Frank, Alberta, and to report whether there appears danger of another slide taking place, thereby endangering life and property, has completed its examination of the parts of the mountain reported to be unsafe, and the several members have returned east.

The commission consisted of Mr. Geo. S. Rice, of Pittsburg, Pennsylvania, one of the senior officers of the United States Bureau of Mines; Dr. R. A. Daly, of the Boston School of Technology, formerly one of the geologists of the Geological Survey of Canada; and Dr. Willet G. Miller, provincial geologist for Ontario. Mr. John T. Stirling, of Edmonton, Alberta, provincial inspector of mines, was also at Frank while the mountain was being examined.

Of course, no information as to the conclusions of the commission has yet been given out, for necessarily these will be included in the report to be made to the Canadian Government, Ottawa. All that is known in

the district is that the members of the commission made a careful examination of the mountain and of such parts of the Canadian Coal Consolidated Company's mine workings as may possibly have in some degree led to a movement of the rock structure above. Whether or not the theory that was several years ago advanced, that the operation of this company's coal mine caused the big slide from Turtle Mountain that occurred in 1903, has been in any way supported by later developments, may be expected to be one of the points upon which the members of the commission will express opinion. The question of whether or not the continued operation of this coal mine, or any part of it in the mountain below the peak (that some fear may fall on the town of Frank), may be regarded as being attended by risk of a repetition of the disaster of 1903, is one of much moment, both to the company owning and operating the mine, and to owners of property and residents in that part of the town likely to be affected should a second large slide take place.

The purport of the report of the commission, and the decision of the Dominion Government after the consideration of the recommendations that shall be made by the commissioners, is being awaited with much interest, and in some cases with anxiety, by those immediately concerned, so it is hoped there will not be any unnecessary delay in disposing of this matter, which is unique in the history of both coal mining and geological phenomena in Canada.

WEST SHINING TREE REPORT.

Chemistry and Mining Building,
Toronto, October 5th, 1911.

T. W. Gibson, Esq.,
Bureau of Mines.

Dear Sir:—

Prof. Miller requested me, on my return from the West Shining Tree district, to submit to you a preliminary report on the area.

The region visited includes the townships of Asquith, MacMurchy, Churchill, and Fawcett. West Shining Tree Lake, near which gold was discovered first, lies in the townships of Asquith and Churchill, and is 70 miles north of Sudbury, 60 miles south of Porcupine, and 20 miles west of Gowganda.

The territory was reached by C. N. R. from Sudbury to Gowganda Junction on Blue Lake, and by canoe the rest of the way, through Blue, Oshawong, Shoo-Fly, Meteor and Opickinimika Lakes and the Opickinimika River. The route leaves the latter river about the centre of the west boundary of Asquith, passing through two small lakes into West Shining Tree Lake.

The country around West Shining Tree Lake is one of low relief. While level and with no prominent elevations, it cannot be called swampy, as the general level is well above the water of the numerous small lakes that occur in the region. The area for the most part is not heavily drift covered but, owing to the level nature of the ground, the rocks are not exposed extensively excepting the part of the country that has been burned over. The forest growth is chiefly spruce, jack pine, balsam, birch, and small cedar.

The geology of the area is rather complex. Numerous samples of rock were brought down but have not yet been examined carefully. The rocks, where the claims are located, are of Keewatin age. They consist of greenstone, altered diabase, and schist. Associated with these are porphyry, rhyolite, and a rusty weathering rock which, I believe, corresponded to the ferrodolomites of the Porcupine district. Very fresh looking diabase was found in several places, and may prove to be post-Huronian. The schists, as a rule, have a strike several degrees north of east, and are nearly vertical but tipped slightly to the north. An area of Laurentian granite lies to the south. Outcrops of the granite were observed along the Montreal River across the Township of Fawcett and on the first small lake south of West Shining Tree Lake in the Township of Asquith. Occasional outcrops of granite were observed along the route into the district as far south as the north end of Meteor Lake.

The discoveries, for the most part, are located on zones of weathered schist containing veins and stringers of quartz that generally conform to the strike and dip of the schist. As to their extent but little can be said, as very little stripping had been done at the time of my visit. The quartz widens in places to several feet, but does not carry this width far till it breaks up into stringers or disappears. On one claim where some work had been done one of these zones had been traced for 8 or 9 chains. The quartz is usually white and contains considerable rust, but on three properties a bluish quartz was found. In some places the quartz and schist contains considerable iron pyrites. Small amounts of galena were observed in two places.

While the most of the quartz veins and stringers have a strike conforming to the general strike of the schist, that is, a few degrees north of east, it was noticed on three properties that the strike of the quartz outcrops was in a northwesterly direction. These suggested that a second system of veins occur in the district.

The following properties were visited:

A. Gosselins' (2195-96), east of West Shining Tree Lake.
S. Jepson's (2277), east of West Shining Tree Lake.
T. Thompson's (2312,2310), east of West Shining Tree Lake.
Moore & McDonald's (2275-76), east of West Shining Tree Lake.
R. Cryderman's, near 2312.
P. McGuire's, south of West Shining Tree Lake.
M. Caswell's (2393), northeast corner of Fawcett.
Jefferson's (2504), southwest corner of MacMurchy.
T. Seville's (2535-36), southwest corner MacMurchy.
McIntyre's, southeast of (2504).
S. Jepson's (2538), southwest corner MacMurchy.
Caswell's (2532, 2542), southwest corner MacMurchy.
G. Bennett's (2544), southwest corner MacMurchy.

Free gold was seen in place at Gosselins', Jefferson's, and Caswell's (2532). Gold was seen panned from the decomposed material on Cryderman's claim.

The property known as Gosselins' has attracted more attention than any other in the district. The stripping already done reveals what is apparently a very large body of quartz with free gold in several places. What is evidently the same body has been located at intervals for over 10 chains with a width of three or four chains. The rock associated with the quartz is a rusty schist and also a hard flinty rock in which a schistose structure has been developed in places. The rocks in places are interseeted with quartz stringers which form, at times, probably one-half of the total. In a place where the most stripping has been done the quartz shows continuously for 2 chains. A trench at almost right angles shows quartz for about 70 feet, but with some streaks of schist. The stripping

has been done in a northwesterly direction, which may prove to be the strike of the ore body.

Another property that attracted attention is that known as Clark's, about one mile in a southeasterly direction from Gosselins'. Work done on this property shows a large mass of quartz and a greenish rock that weathers very rusty. A great deal of pyrite crystals occur in the rock, and sometimes in the quartz. No gold was seen here, but it is claimed that gold can be panned from the decomposed material. This was the most extensive showing of what was considered the carbonate rocks, that I saw in the district.

At the time of my visit to the region definite information regarding many of the properties was difficult to obtain, as many men had gone out to the front or were prospecting in other localities.

* * * * *

Since writing the above, I have received the results of assays from the Belleville office on seven samples of quartz I collected from different properties where no gold was to be seen. One of these samples did not contain gold, and the others carried values ranging from 40 cents to $6 to the ton.

Yours truly,
R. B. Stewart.

The Sturgeon Lake Gold Field.

Abstract of report of Dr. E. S. Moore.*

History of the Field.

According to Mr. W. McInnes, of the Canadian Geological Survey, who seems to have been the first geologist to describe Sturgeon Lake and the geology of its vicinity, gold was discovered on Sturgeon Lake in the summer of 1898, when a number of claims were staked. A little later the most important deposit of the region, now owned by the St. Anthony Mining Company, and at first known as the Jack Lake mine, was discovered, and in 1901 Dr. A. P. Coleman describes the work which was being done on this property. A little to the north of it the Sturgeon Lake Mining Company had erected a stamp mill and installed machinery on the Dawson property, named after G. Dawson, president of the company. Mining continued, with periods of cessation, at the St. Anthony Reef mine, until 1908, when it ceased, and almost no mining work has been done since, although some new camps and other buildings were erected last summer and underground development work was begun.

During the years 1901-2 the United States Gold Mining Company did considerable work on what is known as the Shore properties, near the west end of King's Bay and on claim B. G. 136 on the southwest shore of North Bay. Three shafts were sunk on the former property and a tunnel about 50 feet long driven into a hill on the latter.

The work on those properties being unsatisfactory, they were abandoned the next year, and nothing has been done with them since.

Camps were built and shafts were sunk on the Symmes prospect on B. G. 139, on North Bay, about the same time as those mentioned above. About this time also the camps at the Northern Light and other properties near the northern part of Northeast Bay were erected, but soon fell into disuse.

In 1906-8 there was some activity in the vicinity of Belmore Bay, where the Belmore Bay Mining Company sank a shaft 260 feet deep and built a three-stamp mill, and the Douglas Mining Company did a considerable amount of development work.

In 1909 prospecting received a new impetus through the construction of the Lake Superior Branch of the G. T. P., and the establishment of steamer lines on the lake for the transportation of materials for railway construction. These afforded facilities for easy access to the region, and a good many prospectors entered the district, but the boom was only temporary. On account of the delightful lake, the ease with which the region can be reached and supplies obtained, it has often seemed that many prospectors have found it a very desirable one in which to spend a summer at the expense of someone else, and this has led to the foolish and useless expenditure of time and money on what has been called development work. Efforts have been made to sell properties that are known to be absolutely valueless. Many large pits have been sunk in rock where there is almost no sign of quartz and no gold in what quartz there is.

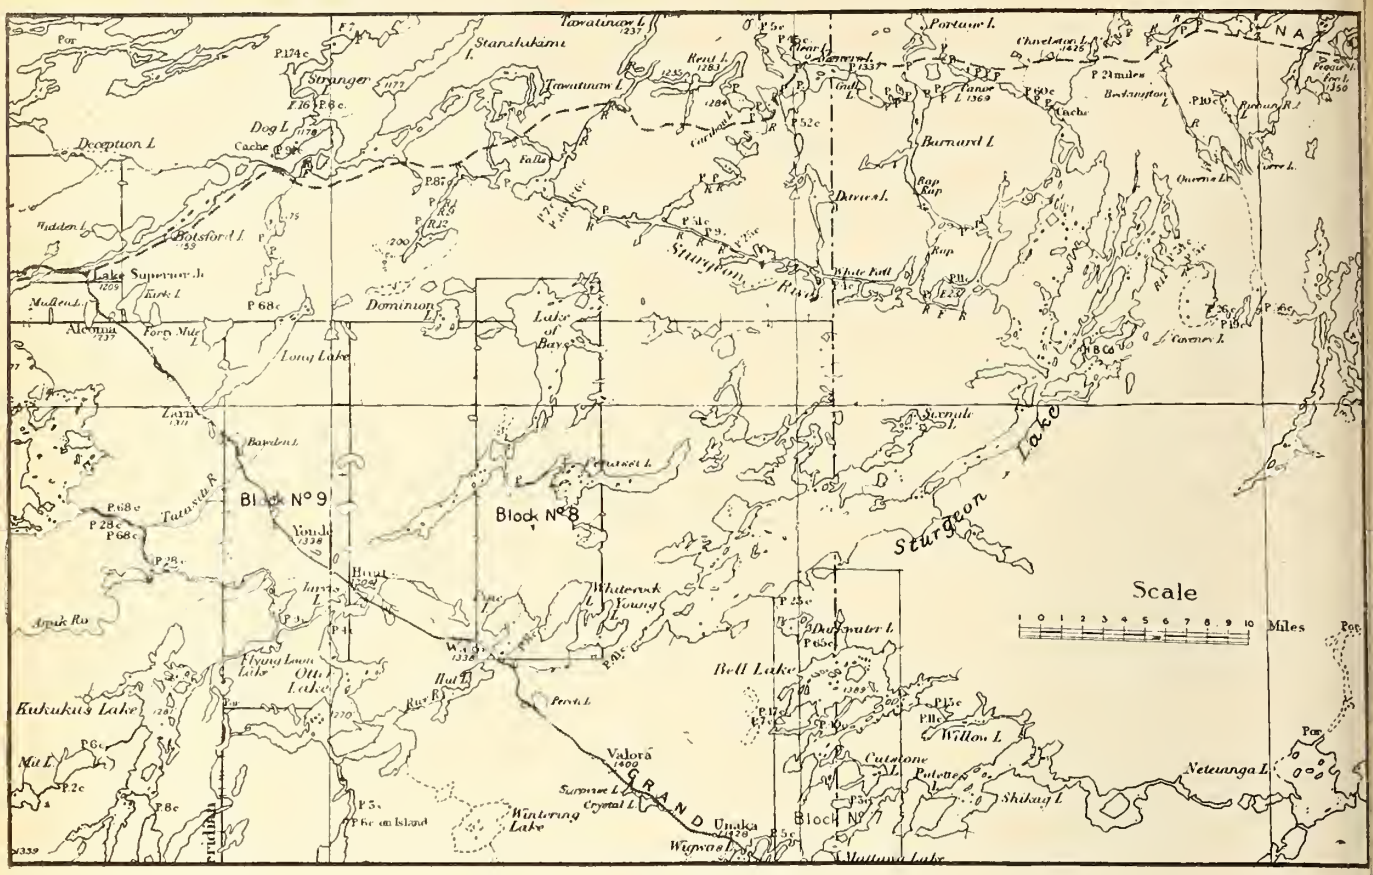
Besides the writers already mentioned, several others have written geological notes on the Sturgeon Lake region. Among these are Dr. W. G. Miller, who in 1902 wrote a good account of many of the deposits. W. H. Collins, of the Canadian Geological Survey, and E. T. Corkill, Inspector of Mines, have written briefer notes on the mines.

The lake after which the field is named is about 45 miles long, and the northern half is divided into two large arms, known as North Bay and Northeast Bay. It lies across the boundary between the districts of Rainy River and Thunder Bay, and in 50 degrees north latitude. A spur line about six miles long runs from the lake to the Lake Superior branch of the Grand Trunk Pacific Railway, at W. O. Junction, about 154 miles from Westfort, near Fort William. The field is thus easily accessible, and when the Transcontinental main line is complete it will pass about three miles north of the lake.

Geology.

The rocks round Sturgeon Lake form an extremely complex igneous series of extrusions and intrusions. There are very few sediments in the area, and none of them form definite geological horizons. The only sediments recognized with certainty were a few patches of greywacke, arkose, and dolomite, the former being found in the open cut at the St. Anthony mine, the arkose at the Dawson and Shore mines, and the dolomite on Claim H.W. 705 and on Morgan Island. Besides these there are some masses of a fine grained gray gneiss or schist, which is believed to be partly sedimentary in origin. It is finer in grain, more granular in texture, and as a rule lighter in colour than the granite gneiss. It is similar to large areas of rock found by the writer in the Lake Savant area.

*From 20th Annual Report Ontario Bureau of Mines.



Key Plan showing position of Sturgeon Lake

The igneous rocks consist of granites and their metamorphic equivalents, gneisses, aplites, quartz-porphyries, rhyolites, hornblende-syenites, diorites, diabases, basalts, gabbros, and porphyrites. Dr. W. G. Miller described boulders of nepheline-syenite which he found near East Bay, but we did not locate any of this rock in our work.

On the accompanying map a number of these rocks have been differentiated, but they are so intermingled that only the larger areas of each type could be laid down, and these areas often include small patches of the other rocks. There are represented a few small areas of agglomerate and breccia, which in some cases are crush-breccias and in others probably flow-breccias and agglomerates, the latter consisting of fragmental material ejected from volcanoes.

An attempt has been made to separate these rocks according to their relative geological age, but the only definite arrangement that can be made is on a purely lithological basis. There are no sedimentary rocks in the area which furnish definite geological horizons. The granite along the western portion of the field, designated the Sturgeon Lake granite because of its prominence in the area, is by no means typically Laurentian, and some of the quartz-porphyries are older, some equivalent in age, and some younger than the great mass of the granite.

Many of the greenstones and schists, as well as the quartz-porphyries, are typically Keewatin, but there are some greenstone dikes cutting the granite, and there are many masses of comparatively fresh-looking gabbro and diorite apparently much later than the older rocks of the area, and often cutting the quartz-porphyries, which are younger than the oldest of the greenstones.

Age of the Granite.

The age and association of the granite is interesting because of the apparent relation between it and the ore deposits, and of the petrographic character of the rocks. This granite has usually been regarded as of Laurentian age and has been mapped as such by previous investigators in this region. It was found, however, that it is not typically Laurentian, as much of it is not gneissic at all and looks like a comparatively fresh rock. The eastern portion of it is porphyritic and in places grades over into quartz-porphyry. None of these features are absolutely opposed to the rocks being Laurentian, but they are not typical of rocks of that age.

It was at first thought possible to separate the granite along the west shore of North Bay, where some of it is metamorphosed to a gneiss and in places cut by numerous granite dikes from a younger porphyritic granite along the eastern portion of the bay which contains few of these dikes. The work on the whole area, however, failed to show any means of doing this, and also indicated that the two types pass into one another by imperceptible gradations. In some places the granite has been locally more metamorphosed than in others, giving rise to the patches of gneiss, and the porphyritic phase seems to be due to differentiation influenced by the contact with the Keewatin greenstones.

The age of the numerous dikes of granite, felsite and aplite, is doubtful. These dikes were first observed near the northern end of North Bay, where they cut biotite-gneiss and a fine-grained grey gneiss or schist the latter probably of Keewatin age. It was thought that they belonged to the later porphyritic granite but they were found to be connected with the main mass of the granite in the vicinity, and later, similar

dikes were found cutting the porphyritic granite on the east shore of the bay. Dikes of felsite and aplite were also found cutting the greenstones at considerable distances from the granite mass. The assumption that there are granites of two distinct ages in this area is supported by the fact that at Unaka, a station of the G. T. P. Railway a few miles east of Sturgeon Lake, there are distinct granite dikes cutting a typical highly metamorphosed Laurentian gneiss. In this case the granite had been folded and metamorphosed before the dikes were intruded, and this was thought to be the case on the northwest portion of Sturgeon Lake, but the pegmatitic and aplitic character of so many of the dikes suggested that they may have originated as a later phase from the same magma as the granite, in some such order as suggested in the next section of this report.

That some of the quartz-porphyry is older than the granite is shown at the St. Anthony mine, where the latter cuts a schistose phase of the former and that there is quartz-porphyry of the same age as the granite is shown by the gradation of one into the other. The small area of porphyry near the mouth of the creek draining Couture Lake cuts the granite and is therefore younger.

The large mass of hornblende-syenite along the east side of the narrows is younger than the greenstones of the region, and is a comparatively fresh rock, but beyond that nothing can be said about its age. It is not improbable that it is related to the Sturgeon Lake granite and of similar age.

As to the age of the dolomite, little can be said beyond the fact that it is older than the quartz veins which cut it in some places.

Regarding the age of the rocks of the area, it is the writer's opinion that there are basic rocks of ages varying from Keewatin to Keweenawan, quartz-porphyries of Keewatin to at least Huronian age, and that the Sturgeon Lake granite is later than Laurentian and is possibly Huronian in age.

Vein Characteristics.

The veins are largely fissure fillings. They are, as a rule, very irregular, because the cavities were formed along contacts between different types of rock, along planes of cleavage and fissility in schists, and in igneous rocks by unequal cooling and torsion. In one case a considerable fissure was opened along a fault plane at the St. Anthony mine.

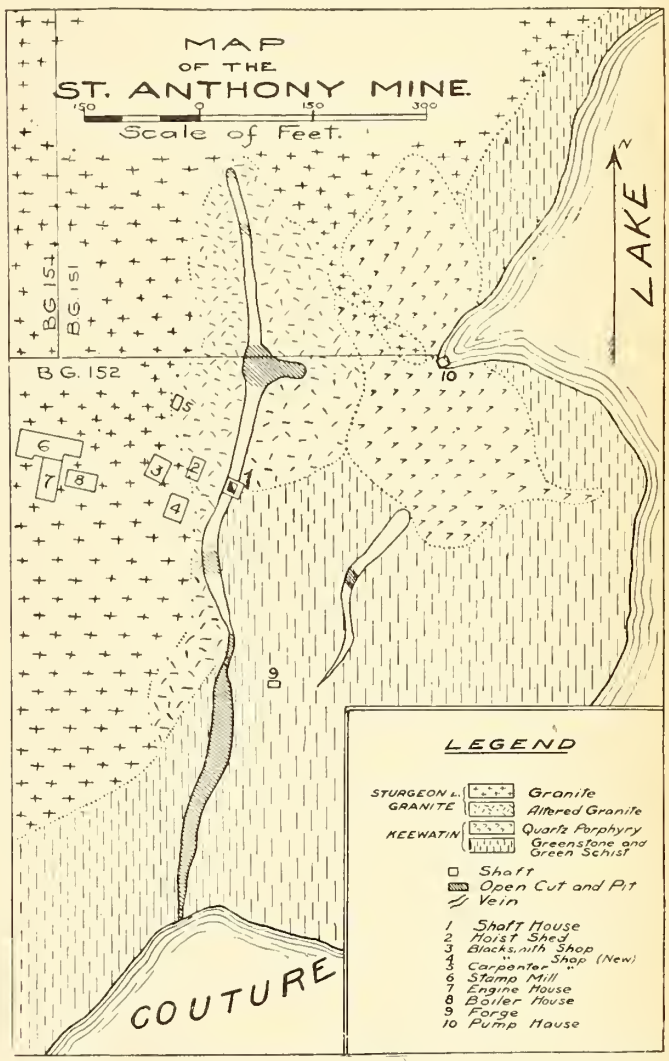
The gangue is predominantly quartz, although some calcite and siderite occur. The sulphides are pyrite, chalcopyrite, galena, zinc blende, pyrrhotite, and pyrousite. The ores are largely free-milling. The upper portions of the veins, owing to oxidation and concentration, often show splendid specimens of free gold.

Four stamp mills have been installed in the region, but only one, that at the St. Anthony mine, has handled any considerable quantity of ore. This mine has produced a good deal of ore, but it is difficult to procure records of the quantity and value. Many shafts have been sunk and a great number of test-pits dug on more than 200 claims which have been recorded in this field.

AL 499.

On an island in North Bay covered by location A. L. 499, and not far east of the last property described, Mr. T. K. Barnard has sunk a shaft and stripped a number of veins. Mr. Barnard has been on this island for seven years, and his beautiful flowers and well-kept cabin deserve special mention. It is probably the best kept and most attractive cabin owned by any prospector in the north.

On this island there is a contact between greenstone in the form of altered diabase, green schist, and quartz-porphyry, which in places becomes more like granite than quartz-porphyry, and may be regarded as a phase of the granite. The veins occur in the greenstone and schist, in the porphyry, and along the contact between the two. The quartz in most of the veins is dark and favourable looking, although one vein appears barren. One of these veins runs nearly across the island. A shaft 25 feet deep and 9 x 7 feet, has been sunk on a group of one large and many smaller veins. In the shaft there is a dike-like mass of porphyry, and there



is some evidence of a slip horizontally part way down the shaft, while at the bottom there is a mass of greenstone. As this greenstone is older than the vein, it has not intruded it, and although the vein may have pinched here it may reappear on either side of this mass.

There are many little stringers in the quartz-porphyry, suggesting that the fissures had been developed at the time of cooling and contraction of this rock. From one of these little veins some gold was panned, and the dark quartz from the shaft also showed fair values, but we did not find any visible gold, and the owner stated that it seldom occurred, although this property has had a local reputation for supplying unusual samples of free gold.

The Symmes Prospects.

On claim B.G. 139, on the shore of North Bay, there are three old camps, and near them some pits. W. G. Miller states in his report that there are two shafts on the Symmes property, which includes B.G. 138 and adjoining claims, about 25 feet apart, and that the southern one is said to be 22 feet deep and the other one 15 feet. He describes the vein as about 9 feet wide, occurring in granite, and consisting of dark quartz carrying iron pyrite, dark sphalerite, and occasionally visible gold. I could not get any definite information in the field regarding these properties, as some of the claims have been abandoned and the Coveney brothers have taken up and partially developed some of the others, which will be described under "The Coveney prospects."

Near the camps on B.G. 139 there are two pits about 100 feet apart and 7 to 10 feet deep on a large white quartz vein. The granite in which the vein lies in the upper portion of the pit as a sort of capping, is much shattered, and the vein is very irregular.

The Coveney Prospects.

On A.L. 497, a short distance from the southeast corner of B.G. 138, considerable prospecting work has

Acid granite dikes cutting arkose and biotite-granite gneiss.

been done by the Coveney brothers. They have sunk three pits, two of which lie near together, on a large irregular mass of quartz near the contact between porphyritic granite and Keewatin green schists. This mass of quartz appears to form a sort of capping from 1½ to 6 feet thick, due to solutions rising from many cracks in the shattered granite and spreading out along some horizontal line of weakness, probably between the greenstone above and the granite beneath, and then exposed by the removal of the greenstone by erosive agencies. The bottoms of the pits show very little evidence of a continuous vein. Where stripped, small dikes of granite are seen cutting the schist, and numerous stringers of quartz occur in both granite and schist.

The largest pit is in the form of a trench about 50 feet long, 10 to 15 feet deep, and 8 to 10 feet wide. Some of the ore taken from this pit was described by Mr. D. Coveney as containing the following assay values:

Silver	$25 per ton.
Gold	6 per ton.
Copper ....$2 to 3 per ton.	

One of the most highly mineralized specimens, taken by the writer and analysed by Mr. N. L. Turner, provincial assayer, showed the following values:

Gold	0.20 oz. $ 4.00) per ton.
Silver	22.72 oz. ($11.36) per ton.

The vein is fairly well mineralized with chalcopyrite and pyrite. The latter is sometimes in cubes one-half an inch in diameter, and in some places the pyrite has been dissolved, leaving cubic cavities in the quartz filled with iron oxide.

The contact between Sturgeon Lake granite and Keewatin schist runs nearly north and south in this vicinity, and about 100 paces south along the contact there is another pit on a large quartz vein. This pit is about 12 feet deep and varies in horizontal dimensions from 10 x 7 feet at the top to 6 x 5 feet at the bottom. There was a little water in the pit, and at the surface of the water the vein widens out to practically the full width of the pit. The upper portion of the vein is very irregular and is mixed with bands of schist. It strikes 160 degrees, dips 80 degrees W., and where stripped can be traced 150 feet up the hillside, where it either pinches out or is turned off in another direction by a change in the strike of the schist, which at this point changes in strike to a northeast direction. Throughout this 150 feet it keeps its width well, and the footwall is fairly distinct.

The St. Anthony Mine.

The St. Anthony mine is situated on claims B.G. 151 and 152, on the west shore of Couture Lake. The camps are located on B.G. 154 and 168 on St. Anthony Bay, a small indentation in the shore of North Bay of Sturgeon Lake. The camps, as well as some of the buildings at the mine, have been renovated during the past summer, preparatory to the carrying out of further development work at the mine.*

This property, which is by far the most important one in the district, was located about ten years ago, when it was known as the Jack Lake mine. It also goes by the name of the St. Anthony Reef, because of the idea held by some that its surroundings suggested a reef rising above the water of Couture Lake. It has been controlled for some time by the St. Anthony Mining Company, and was worked from the year 1903 until 1908, when it was closed down. During 1907 and 1908 Mr. J. Steele worked the mine under option. The present manager of the company is Mr. Arthur L. McEwan, to whom I am much indebted for his hospitality to us while working in the vicinity of the mine.

The buildings at the mine consist of a ten-stamp mill and amalgamation plant, boiler, engine, and shaft house, carpenter shop and blacksmith shop. The sulphide concentrates from the mill have been stored pending better shipping facilities.

The general plan of the mine and the geology in its immediate vicinity is shown on the accompanying sketch map. The mine workings consist first of an open cut extending almost north and south along the main vein from Couture Lake. This cut is over 300 feet long and reaches a maximum depth of 40 feet and width of 25 feet. The width varies from about 10 to 25 feet, and the greater portion of the material removed was milled. In the bottom of the open cut shaft No. 3 is found, and it extends 100 feet below the surface. About 220 feet north of this shaft No. 2 has been sunk and a drift connects the two shafts, most

---

Editor's Note: This report was written in the summer of 1910. The St. Anthony is now producing gold.

of it lying along the vein. At the botom of No. 2 a crosscut runs west 30 feet to pick up the vein, and then a drift south 67 feet and another crosscut east to the north and south drift between the shafts. A crosscut is said to extend east 125 feet from the bottom of No. 2 shaft. The hoisting is done from this shaft, which is timbered.

From the west end of the 30-foot crosscut from shaft No. 2 a drift runs north 180 feet to an upraise known as No. 1 shaft, and from the opening a drift is said to continue further north 160 feet. No mine maps were available at the time of my visit, and these figures are compiled from several sources.

Besides the open cut there are on the surface a number of pits as indicated on the sketch map, but none of these are very extensive. The rocks in the vicinity of the mine consist of Keewatin greenstone, schist, and schistose greywacke, intruded by quartz-porphyry, and the whole intruded by the later Sturgeon Lake granite. The granite in this vicinity is porphyritic and highly altered by hydrothermal action, where chemically active waters have acted on the rocks. The main vein runs in the granite close to contact for some distance, and then leaves the granite and extends out into the schists. There seems to be good evidence that when the granite cooled and shrunk, the adjacent rocks were broken and shifted so that a fissure could be filled with quartz and calcite. From the appearance of the walls on the sides of the open cut it looks as if the rock on the east side of the fissure moved north and that on the west side south. At the time this large fissure was formed countless smaller ones were developed, so that there is a zone about one-quarter of a mile wide, more or less streaked with quartz veins, and in places the walls of the main fissure become indistinct in the granite. In the walls of the veins the granite has been so altered that most of the feldspar has disappeared, and the rock has turned into a greenish-yellow protogine, consisting almost entirely of quartz and muscovite.

The gangue in the granite and schist is largely quartz, but some calcite occurs in both rocks and in greater proportion in the latter. Some siderite is also present where the vein cuts the schist. In the open cut in the schist, the walls are distinct, although the quartz is often distributed in narrow veins along the planes of cleavage, and the whole mass from wall to wall contained more or less gold.

The minerals in the gangue are free gold, pyrite, chalcopyrite, sphalerite, and galena. Beautiful specimens of free gold have been obtained from this mine. Much of the ore is free-milling, but with depth the sulphides appear more abundantly. The ore from the schists contains less sulphides than that from the granite, and this seems to be due to the greater ease with which oxidizing waters percolate the schists. The writer was informed while at the Athabasca mine, near Nelson, B.C., that similar conditions existed there where the ore occurs in porphyritic granite and schist.

No assays of the ore were made by the writer, but the manager states that much ore was mined which ran as high as $85 per ton, and that there is still in the mine a good deal of ore which will average $12 per ton. It is not unlikely that with depth the quartz veins will become less clearly defined in the granite, it being probable that most of these veins were formed in the outer and upper portion of the granite magma when it cooled, before the mass as a whole was completely solidified.

During the past summer new interest was taken in this property, and considerable work was done in the way of putting up new buildings and making a start at development work by sinking in No. 3 shaft.

This property has been described by other writers, and references are given in this report in the section on the history of the field.

The English River Gold Mining Company.

On location B.G. 157 is what is known as the Dawson mine, now owned by the English River Gold Mining Company, and formerly controlled by the Sturgeon Lake Mining Company. Like the St. Anthony, it is situated near the contact between the green schists and granite, but instead of lying on the main contact, it lies on the contact between bands of schist and arkose cut by the granite. There are here a number of pegmatite dikes, in some parts composed of about half feldspar and half quartz, and in other parts consisting largely of one or the other.

The gangue is quartz, and the ore minerals found were galena, sphalerite, pyrite, and chalcopyrite. Good specimens of free gold are said to have been found, though we were unable to find any on the dump.

The workings include a shaft, open cut, and some pits, the former being full of water. The shaft is said to be 64 feet deep, and the open cut is about 70 feet long, 10 feet deep, and 5 to 6 feet wide. Much of the country rock is included in this width.

The buildings include a mill containing ten stamps and other equipment, but the mill has been long idle.

Prospects on Couture Lake.

There are a great number of prospects in the vicinity of Couture lake, but it is possible to describe only a few of them here.

On the large island northeast of the St. Anthony there are some large quartz veins in schist. None of these have been developed, and Mr. Miller has already described them. One of these gave an assay of $2.75 per ton in gold.

On claims A.L. 656 and 657 there are a number of pits and one shaft. These are controlled by Messrs. King and Frazer. The shaft is said to be 75 feet deep. The vein of quartz and calcite is about 8 inches wide, and has a pretty distinct hanging wall. It carries some nice specimens of visible gold. The vein can be followed over a portion of two claims, and although it is largely in green schist, it is closely associated with a narrow band of comparatively fresh-looking quartz-porphyry, in which is some of the quartz, and some of it along the contact between it and the schist. The vein shows a tendency to break up into stringers in some places, and is small, although the quartz looks favourable as a carrier of gold.

To the north of the shaft, on some claims worked by Mr. Fawcett, are a number of pits on veins which in some places show visible gold. North of these claims there are a good many pits, most of which are of no interest.

On the west side of the lake, on claim A.L. 662, there is an old shaft at least 20 feet deep, containing a good deal of water. The vein is about 2 feet wide and dips 30 degrees west. It fills a fissure between a footwall of schist and a hanging wall of altered greywacke. The vein is mineralized with chalcopyrite, galena, sphalerite, pyrite, and a little pyrrhotite. A little free gold was found in some specimens of quartz believed to have come from the shaft.

Prospects Around Ouillette Lake.

There are a large number of prospects in the vicinity of Ouillette Lake, lying north of Couture Lake.

Many of these consist of little pits of no importance, but the Ouillette Lake Mining Company, with headquarters at Sault Ste. Marie, Ontario, has done much prospecting work on nine claims northeast of the lake. Outside of the two old locations S.V. 421 and 422, none of the claims has been surveyed, but they adjoin on the east and south.

One pit about 25 feet long runs across a mass of schistose diorite, and the rock is cut up with stringers of quartz. The gold carries considerable pyrite and pyrrhotite, and a number of specimens of free gold were seen.

In another pit about 15 feet long and 7 feet deep a mass of white quartz stringers about 10 feet wide may be seen lying along the hanging wall. The rock has about the composition of diorite. On the surface near this pit there is a quartz vein about 3 feet wide which may be connected with the mass already described. It pinches down to about 20 inches in a pit 10 feet deep.

On location S.V. 422 there is a pit on a large mass of quartz. The pit is about 14 feet wide, and the quartz extends almost across it.

On another claim a mass of stringers appearing on the surface unite in a pit to form a vein about 8 feet wide

The rock in which the veins occur is largely coarse greenstone, the gangue is mostly quartz, and the other minerals in the vein chalcopyrite and pyrite. The veins in places form some of the largest in the region, and some of them carry gold, but they show a tendency to break up into small stringers or otherwise become irregular.

The Powell Property.

On the west shore of Northeast Bay, on Claim A.L. 701, there is a deposit locally known as the Powell property. Last summer it was developed for Mr. Beidelman under the management of Mr. Atwood, who was formerly with the Douglas Mining Company. The workings lie on a vein, consisting of attractive-looking quartz, beginning near the lake shore and running a little west of south. There are a number or pits, and two of them were about 25 feet deep, but neither was timbered at the time of our visit. The rocks consist of a complicated mixture of quartz-porphyry, grey schist, and greenstone, and the vein lies sometimes in one rock and sometimes in the other, and in places along the contact between the two. It varies in width from 2 to 15 inches, and frequently breaks up into stringers, especially at the contact between different types of rock. The quartz is well mineralized with pyrite and chalcopyrite, the latter frequently altered to malachite and azurite. We had no difficulty in finding good samples of gold at a depth of 20 feet. These gold specimens are doubtless due to the secondary enrichment process, as they occur in association with the secondary carbonates of copper.

Near the pits described there are a number of smaller ones on this same vein, which fingers out a little farther south.

Other Deposits on Northeast Bay.

On the long point running south, just west of the island covered by S.V. 414, Mr. George Day has staked a number of claims which have not yet been surveyed. On these claims there are some pits on irregular quartz veins in quartz porphyry and along the contact between the quartz porphyry and green schist. The quartz is often disseminated in the porphyry, and appears in places like veins filling cracks in a partially cooled molten mass, though the veins may be later impregnations by hot solutions along lines of weakness. The rock is usually much decomposed along the veins, while the veins and rocks, especially near the fissures, are impregnated with iron pyrite, in some places with cubes one-quarter inch in diameter. In one place a beautiful specimen of gold was seen in a space left by the removal of one of these cubes, and in the oxidized and decomposed rock free gold could be found by panning. Gold in any quantity seems to be limited largely to the upper portion of the deposits, which have been oxidized, and it seems probable that a considerable amount of the quartz may have been collected into these veins by the partial decomposition of the surrounding rocks and the segregation of the quartz under the action of organic acids. The organic acids, no doubt, have had a good deal of influence in dissolving and concentrating the gold which would be freed from mechanical union with the pyrite by the oxidation and removal of the pyrite in the form of ferrous sulphate.

Many other small deposits occur in Northeast Bay, but they seem much alike and too numerous for description.

Prospects on Belmore Bay.

Since the year 1906 the region around Belmore Bay has attracted considerable attention, as there are many veins within about three miles of the lake. The Douglas Mining Company has camps on the east short of the bay and has sunk a couple of shafts. On claim P. 7 there is a shaft said to be 22 feet deep on a vein varying in width from 3 inches to 2 feet. A test-pit near by shows stringers running through the schist. On the same claim and 98 paces distant from the 22-foot shaft there is another one 73 feet deep on the same vein. The rock from the bottom of the shaft consists of grey to white quartz scattered through schist and mineralized with chalcopyrite and pyrite.

There seems to be little galena or zinc blende in this region, and the same can be said of the deposits on the northern part of Northeast Bay, while around Couture Lake and North Bay these minerals seem to be more common.

On what is called the Ruby property, owned by the Douglas Mining Company, there is a shaft said to be 30 feet deep on a mass of quartz stringers about 4 feet wide, in dark greenstones varying in composition from diabase to diorite. North of this shaft 100 feet and on the same vein is a pit about 22 feet deep where the vein varies in width from 3 inches to 2 feet. The veins run in a general northeast direction with the strike of the rock and with a dip 60 degrees northwest.

The gangue here is quartz of good quality and calcite. It contains pyrite and chalcopyrite, and specimens of free gold were seen in calcite and quartz.

The other company which has done much work in the vicinity of Belmore Bay is the Belmore Bay Mining Company, which owns a number of claims just east of the lake. It is said that the shaft near Mud Lake, where the camps are situated, is 260 feet deep, and very little ore came out of it. A three-stamp mill has been erected on the shore of the lake, but it did not run long.

Besides the properties described, there are many prospects unnecessary to mention, as most of them are pits on small veins or stringers and a description of one serves for almost all. The rocks in the area are mostly coarse greenstones, not as a rule very schistose, syenite porphyries, quartz porphyries, rhyolite tuffs, and plagioclase porphyries with very large phenocrysts

sometimes an inch in diameter. The veins are as a rule very irregular, frequently breaking up into stringers, pinching out or expanding to form masses several feet in width. The metallic minerals are predominantly chalcopyrite and pyrite, with considerable pyrolusite in some places.

Free gold was seen only on a few claims. Some of the veins are associated with aplite and felsite dikes. In one case an aplite dike cuts a syenite porphyry, and near it there are crystals of ilmenite. The rock has been brecciated, and the cracks filled with calcite, carrying chalcopyrite and pyrite. The ilmenite may have been developed as a contact metamorphic mineral.

On Morgan Island, just west of Belmore Bay, is a mass of rhyolite tuff in places, impregnated, especially near its contact with quartz porphyry, with calcium and iron carbonates, which are mineralized with copper and iron pyrites and galena. The tuff, in a band about 100 feet wide, is composed of angular fragments of rhyolite, and the whole mass is reddened by the alteration of the iron bearing minerals. This deposit has not been found to carry gold to any extent.

On East Bay are a number of abandoned prospects, and on the east side of the narrows about five miles below Sturgeon Lake hotel there is a pit on a vein of calcite. Associated with the vein there are besides calcite, apatite, tourmaline, hornblende, zircon, pyrite, and chalcopyrite and, it is said, values in silver.

As there are in the Sturgeon Lake gold field hundreds of pits, many of them of no importance and the majority of them having characters in common, it is impossible to describe them all, and it may be that some left unmentioned are as important as some of those described. An attempt has been made to indicate on the accompanying map the shafts and many of the pits, but many pits and strippings have necessarily been omitted, as it would require too much detail to plot all of them.

Economic Possibilities of the Sturgeon Lake Gold Field.

Having spent considerable time in studying this field it might be well for the writer to express, from a geological standpoint, his opinions regarding its future.

A study of the region shows that gold is widely distributed, and that one can locate a vein, small or large, in many parts of the area. These veins are, however, as a rule, very irregular and uncertain, not having been formed by any widespread movements which opened extensive fissures, but rather by cooling and shrinking of igneous rocks and slight movements along contacts and cleavage planes. The fissure at the St. Anthony is the only one which can be regarded as an important exception to this rule, and it is the only deposit which has given promise of really making a mine.

While this area has been remarkable for the large number of fine specimens of free gold, these have been the products of secondary enrichment and concentration, and are not likely to continue to great depths. With the absence of much free gold at depth, few of the veins show a sufficient increase in the sulphide ores to counterbalance the diminution of the free gold. As the region has for so long been exposed to erosive agencies, it is probable that much material from the upper portions of the veins has disappeared, and with it considerable gold. The low relief and the scarcity of streams are also against the possibility of valuable placers being found.

Much unprofitable work has been done in the area, partly because many of the prospectors lacked experience, and partly because, as already mentioned in this report, some men having charge of the work were doing it at the expense of others. While there are plenty of veins in the region, many mere stringers of quartz have been exploited without any justification, largely because the region is easily accessible and an attractive one in which to work. In the future those who wish to carry on proper exploratory work should profit by the experience of most of the other companies which have operated in the region, and not build stamp mills before they have enough ore in sight to justify such an expense.

Consolidated Mining and Smelting Co. of Canada, Limited

Managing Director's Report.

Trail, B.C., August 25th, 1911.

To the Directors of the Consolidated Mining and Smelting Co., of Canada, Limited.

Gentlemen,—I beg to submit the results of the Consolidated Company's operations for the year ending June 30th, 1911, including Balance Sheet, Profit and Loss Account, Production, and General Report.

Financial Statement.

Operations for the year under review show a net profit of $202,278.29, after writing off depreciation on plant and equipment $193,342.27 (as compared to $175,502.60 for last year), sundry items including bad debts $3,162.31, and charging to profit and loss $438,354.54 expended on development of our various properties. The increase in depreciation is accounted for by the writing off of the Snowshoe equipment, the lease having terminated, and heavy depreciation on the St. Eugene plant, which is liable to close down at an early date.

Additions to plant and equipment during the year amounted to $146,350.30, from which is to be deducted sales of plant to the amount of $11,699.87, or a net amount of $134,650.43. Increase in lands at the smelter is $12,611.57, making the total charge to plant account.

Expenditure on account of the purchase and development of new properties amounted to $217,613.90, which was provided for by the issue of new shares to the value of $250,000.

This amount was expended in purchasing stock and bonds of the Fort Steele Mining & Smelting Company, and the Sullivan Mining Company, owning the Sullivan group at Kimberley; in the purchase of property surrounding the Sullivan; on the development of the Number Seven and Molly Gibson groups, and other small purchases.

The amount due to banks for borrowed capital has been reduced to $584,031.95, a decrease of $181,980.65 for the year.

Quotations for London Lead and New York Silver show slight increases over last year, the average being: London Lead, £12.953, as compared with £12.921 during the previous year; New York Silver, 53.696c., as compared with 51.948c.. Electrolytic copper was lower, averaging 12.337c., as compared with 12.981c. for the previous year.

Production.

The gross value of metals produced at the company's smelting works for the year was $4,437,901, as compared with $5,911,767 for the previous year, a decrease being shown in all of the metals. It will be noted that

there is an increase in the production of the Centre Star and Sullivan groups, that the Molly Gibson and Number Seven have entered the list of shippers, and that the remainder of properties show a decrease.

The large decrease in total production is due to the working out of the St. Eugene, dropping the Snowshoe lease, and to the fire in the Slocan a year ago, which closed down the Kaslo & Slocan Railway and caused a large decrease in shipments from that district.

In our Rossland mines, ore developed and shipments have about balanced. Although the tonnage developed is numerically less than for the previous year—194,000 tons, as against 245,000 for the year 1910—the average value of the ore developed this year on the lower levels is considerably higher.

In the Centre Star and Idaho mines no ore has been developed in the lower levels and but little work done, most of the development having been confined to levels

Year Ending June 30th, 1911.

	Tons Ore.	Gold in Ounces.	Silver in Ounces.	Lead in Pounds.	Copper in Pounds.	Gross Value.

*For the year only; previous records not available.

Development.

The total amount of development work underground in the company's mines is about as follows:

	Feet.	Miles
Centre Star group	146,288.5	27.70
St. Eugene group	103,102.5	19.54
Richmond-Eureka	7,003.0	1.32
Phoenix Amalgamated	2,581.0	0.48
Molly Gibson	6,985.0	1.32
Sullivan	15,162.0	2.87
Number Seven	5,479.0	1.03

During the year 22,452 feet of narrow work and 38,757.3 feet of diamond drilling have been done, as follows:

	Drifting and Crosscutting.	Raising.	Sinking.	Total.	Diamond Drilling.
Centre Star Group	11,290.5	1,803.0	290	13,383.5	25,622.3
St. Eugene group	2,223.5	1,469.0	24	3,716.5	4,346.0
Richmond-Eureka	667.0	295.0	...	962.0	.....
Molly Gibson	340.0	110.0	20	470.0	.....
Sullivan	1,322.0	431.0	45	1,798.0	8,789.0
Number Seven	1,977.5	98.5	46	2,122.0	.....
Total	17,820.5	4,206.5	425	22,452.0	38,737.3

above the 10th. In these a number of small ore bodies have been opened up and one or two larger ones of lower grade. The same is true of the Iron Mask.

The greater part of the new ore that has been found has been in the lower levels of the War Eagle. A winze sunk from the 12th level opened up ore to a depth of 150 feet and of a length at the bottom of 200 feet. Values of this ore are very good. The 10th and 11th levels are also producing a large tonnage of good ore.

In the St. Eugene group no new large ore bodies have been discovered and the ore reserves are practically depleted, being estimated at 6,000 tons. Enough ore is being found from time to time to keep the mine running at a small profit.

The Richmond-Eureka group continues to produce a small tonnage, though an estimate of the probable tonnage is difficult on account of the variable nature of the ore bodies. No large new ore body has been discovered.

A few tons were shipped from the Phoenix Amalgamated during the winter, but as the grade was unsatisfactory at the points where work was done, and as the price of copper was so low, it was thought advisable to do no more work there until conditions improved.

The Snowshoe lease has been abandoned, as it was no longer profitable, owing to low prices for copper, higher costs of mining, and conditions at the smelter which made the use of the Snowshoe ore no longer valuable as a flux.

The lease and bond of the Queen Victoria mine has been abandoned for the same reasons.

The Molly Gibson mine has commenced shipments and with about 14,000 tons of milling and shipping ore in sight and good prospects below the lower level, will, we hope, continue to be profitable.

Development on the Number Seven mine has proved disappointing, both as regards the continuity of the ore bodies and their grade. Work is now being done on the lower levels in an attempt to locate further ore bodies of good grade.

New Properties.

During the year the company has acquired a majority of the stock of the Fort Steele Mining & Smelting Company, Limited, owner of the Sullivan mine. The lease to the Consolidated Company expired on June 30th, and the Fort Steele company is now operating the property and shipping ore to Trail. The mine is producing between 2,500 and 3,000 tons per month of ore containing approximately, lead 20 per cent., silver 6.6 ounces.

Since the close of our fiscal year, arrangements have been completed with the liquidator of the Le Roi Mining Company for the purchase of all the property of the Le Roi Mining Company in Rossland. This property still has a large amount of low grade ore, and some prospects of finding ore of a better grade, and we believe that the purchase will be a profitable one.

Construction.

Construction for the year consisted mainly of the equipment of the Molly Gibson mine with an aerial tramway about four and one-half miles in length; repairs and improvements to the old tramway, which was badly damaged by snowslides; new bunkhouses at the mine; improvements in the mill; horses and wagons for hauling ore, etc.; finishing the equipment of the Number Seven mine, and increasing the roasting capacity of the smelter by the installation of two Dwight and Lloyd roasters; the purchase of lands near the smelter to protect us against claims for damage by smoke; sundry small improvements.

General Conditions.

The past year has been in many ways an unfavourable one for the company. The early part of the year was marked by the low grade of the Rossland ores and limited tonnage, particularly in reduction of tonnage from the St. Eugene due to the working out of the principal ore bodies, and from the Sloean, due to bad forest fires and the consequent interruption of service on the Kaslo & Sloean Railway, which condition unfortunately still exists. Unfortunate weather conditions in the Crow's Nest Pass during the month of February, and interruption of coke shipments on this account, lessened the tonnage of the furnaces at Trail to a considerable extent, and finally, the present strike in the Crow's Nest Pass has lasted from the first of April until the present time, and has not only forced us to buy coke in Pennsylvania at greatly increased cost, but has, more or less, unsettled traffic conditions and increased our cost of handling material, such as coke and limestone, at the smelter. In addition we have been put to greater expense for coal supply. All these causes have made great inroads into profits for the year and account almost entirely for the reduction from last year.

With regard to the future, developments in the Rossland camp during the past six months have been favourable and give promise that this next year at least will be a profitable one in that direction, and there is good reason to hope for some time after that.

The loss of the St. Eugene tonnage has been serious, but will be partly overcome by the operation of the Sullivan, in which the mineral bearing area has not yet been thoroughly prospected. There seems, too, to be good grounds for the belief that new and profitable mines will be opened up in other parts of the Kootenay, and provided some means is found for the proper protection of the lead industry by the Dominion Government, either by a renewal of the bounty on lead when that bounty expires in about eighteen months, or by an adequate duty on lead coming into Canada, prospects for the Kootenay country are, on the whole, bright.

Considerable interest is being taken this year in lead properties throughout the country, and some promising prospects have been opened up. We have continued the policy of the Company of adding to our list of properties by keeping men in the field looking up such prospects this summer and hope that in this way we may be able to add to our tonnage of profitable ore.

Management.

In conclusion I wish to express my appreciation of the hearty co-operation of those in charge of the various properties or departments as follows:

S. G. Blayloek, assistant general manager; T. W. Bingay, comptroller; A. J. McNab, superintendent of smelter; J. F. Miller, superintendent of refinery; M. E. Purcell, superintendent of Centre Star group of mines; Charles Biesel, superintendent of mines at Phoenix; C. H. McDougall, superintendent of St. Eugene mine; A. W. Davis, superintendent Molly Gibson mine; W. A. Cameron, superintendent of Richmond-Eureka mine; James Buchanan, metallurgist; John M. Turnbull, mining engineer; and W. M. Archibald, mining engineer.

Respectfully submitted,

R. H. Stewart, General Manager.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Glace Bay: Dominion Coal Output.

The season of open navigation for 1911 is nearing the close. The outputs of the Dominion Coal Company during the past summer were larger than for any previous continuous period. The total output for the six months, May to October, inclusive, reached about 2,125,000 tons, an average of over 354,000 tons per month. The monthly outputs were as follows:

May	352,119
June	367,014
July	369,930
August	387,927
September	324,342
October, estimated	324,000
Tons	2,125,000

In the months of September and October the output declined, but this was due to dulness in the coal market, and not to any diminution in capacity.

Unusually large storage banks were laid down in the early part of the year, but these have now been all lifted. So far as it is possible to judge the prospects for winter shipments indicate a slightly lowered output during the coming six months when compared with the shipments which were made last winter.

The disproportion between summer and winter outputs is every year growing less noticeable. In 1893, when the Dominion Coal Company was incorporated, the total output from November to May was only a little over 200,000 tons, and it was not until 1900 that this state of affairs became ameliorated. In the winter of 1910-1911 the output was approximately 1,800,000 tons, fully half the annual output. It is a far cry from 1893.

The term of the agreement between the P.W.A. and the Dominion Coal Company, by which the terms of the Shortt award were renewed for two years, expires at the end of this year. Negotiations have already been begun, and it is understood that the company has offered the men a renewal of the two years' agreement on exactly the same terms as before. It is to be hoped that it will be possible to renew this agreement, as it will mean settled and harmonious conditions for some time to come. This is particularly desirable in view of the large programme of capital expenditure which the Coal Company has undertaken, coupled with the dulness of the coal trade, and the persistent inroads on the St. Lawrence market which are being made by United States operators.

The season's programme of new construction is well advanced. The new Siemens-Ilgner electric hoisting engine for hoisting water from the International water-shaft, is in successful operation. The uniformity of the load on the transmission line is in marked contrast to the previous hoist, which was not provided with any compensating device.

At No. 2 colliery a large Walker fan is being put in position to serve as an auxiliary or emergeucy fan in case of breakdown of the present ventilating arrangements.

The coal-handling plant at No. 2 is running, and is expected to effect a notable economy. The large boiler plant at this colliery was designed for automatic coal-handling, and the addition made this year will complete the lay-out.

Delivery of the large electric hoisting engine for No. 14 colliery is expected early in the new year. No. 14 is getting 1,100 tons daily with the present inadequate hoisting engine, and may be expected to make a much better showing when the new hoist is installed.

Part of the framework of No. 15 bankhead is being erected. It is intended to have this bankhead in full operation for the 1912 season. The smaller colliery buildings at this mine will all be completed this season.

With the new electric hoist at International water shaft, the electric air-compressors at Nos. 12 and 14 collieries, and the bankhead at No. 14, in addition to the previous load, the central power station at No. 2 is being heavily drawn upon, and in view of the intention to install still more electric machinery at the Lingan collieries, it is expected that a large electric power station will have to be provided for the Lingan side. This will probably be undertaken next year.

The railway connection to the Birch Grove collieries has been somewhat delayed by lack of labour, but it is expected that it will be finished before the winter sets in. Two sets of slopes are now being driven, one set at the point where the seam was originally opened, now known as No. 21 colliery and a second set about half a mile away at the site of No. 2 colliery.

The rescue station at No. 12 colliery is completed. The equipment will shortly be provided, and in the meantime a few apparatus from the Glace Bay collieries will be sent over to No. 12, and training of the men in their use will be commenced.

The company is sending the superintendent of its main station to the National Field Day at Pittsburg which will be held at the end of October by the First Aid Societies. The proceedings should be well worth watching. Some day in the future it is to be hoped that in Canada also the First Aid movement will be taken up with the enthusiasm it deserves. Up to now there has been a decided lack of ambulance training among the Nova Scotian workmen in all trades, and many a death and mutilation has taken place which a little first-aid knowledge promptly applied might have prevented, to say nothing of the needless suffering which a lack of this knowledge entails.

Springhill.

The output for September was 31,000 tons. The daily output now averages 1,500 tons, and has on several occasions been near 1,600 tons, which is fully up to normal. A large amount of repair and cleaning-up work has been necessitated by the long idle time caused by the strike, but this is now about finished. A new air-compressor is being installed, and it is proposed to shear the coal in some sections. At the present time the coal is all hand-got, and no explosives are used. By shearing it is expected to get a larger product, and to effect considerable economy. Before very long much larger tonnages may be expected from Springhill. For October the output will be over 35,000 tons, at the present rate.

ONTARIO.

Cobalt, Gowganda, and South Lorrain.

During September the Crown Reserve Mining Company shipped 250,000 ounces of silver, and the total production for the first 9 months amounts to $2,376,000 ounces. This month the company has shipped a car of 120,000 ounces to the Kingdom of Saxony.

Operations on the 150-foot level of the Savage have opened up a good ore body on the new No. 4 vein. The values in this vein are not as consistent as in other leads on the property, but the wall rock yields good milling ore.

Dividend No. 33 has just been declared by the Temiskaming & Hudsou Bay Mining Company. The 300 per cent. issue means a disbursement of $23,283. This is the fifth dividend paid by the company this year. Altogether the company has paid 18,700 per cent., or $1,451,307 on a capitalization of less than $8,000.

The Temiskaming Mining Company has started to sink its main shaft to the 650-foot level. At the lowest level where crosscuts have been made, namely, the 575, there is one shoot of very rich ore. Where the diabase is encountered on this level, values cut out.

The Beaver Consolidated Mining Company has at length decided to build a concentrator treating low grade ore. The mill will have a capacity of 50 tons a day, and will differ from the ordinary practice in the Cobalt camp, in as much as two crushers a ball and a pebble mill, will take the place of stamps.

The shipments from the Cobalt camp for the month of September totalled 2,387.52 tons, which was a few tons lower than the previous month. Nineteen mines figured on the shipping list, contributing a total of 75 cars. While the tonnage shipped from the camp for the first nine months of the year is considerably less than that for the same period of 1910, the value of the ore is higher. It is estimated that the 12 months will

how an increase of at least $1,000,000 above that of 1910, which, it must be remembered, was far ahead in production of ny other year.

During September the Nipissing mined ore of an estimated et value of $227,082, and shipped ore of an estimated uet alue of $239,843. Favourable developments were encountered nderground at veins 73, 148, and 123. Owing to the non-arival of the big pump, hydraulicking operations for prospecting urposes will not be attempted until next spring. To develop hat part of the conglomerate area lying near the Savage mine, main working shaft is now being sunk. This will be used or the purpose of underground exploration.

One feature of the shipping list for the past month has been he re-appearance of the Drummond. The old workings at No. 1 shaft are now being cleaned out, and are yielding unxpectedly in low grade ore. Excellent terms have been made vith the Denver smelter owing to the fact that the rock is ighly silicious, and therefore very desirable as a flux.

The Lumsden Mining Company is opening up the Rochester nder contract. The crosscut on the 300-foot level is now 200 eet from the Lumsden shaft. The intention is to cut several alcite stringers that were found at the edge of Brady Lake.

The annual meeting of the City of Cobalt Mining Company howed that there was cash in bank, $31,954, with ore at smelter $26,860, and metallics on hand and ready for shipment nother $2,000. During the year 292,694 ounces were produced from 392.04 tons of ore. All the old directors were relected. The management report the cutting of another small ein at the 265-foot level.

Porcupine, Swastika, and Cripple Creek.

Mr. Harold Kingsmill, who for about a year has been manager of the Rea mines, has resigned his position to go to Peru. While no successor has yet been appointed, the property will e controlled and developed by Mr. Williams, resident manager or the Bewick-Moreing Company in the camp.

The most important development in the Porcupine camp to late is probably the discovery of ore bodies 700 feet below the urface on the Pearl Lake claims. While no average assays re given, it is important to note that consistent values are o be found at this depth in the Pearl Lake field. Mr. G. W. Thompson, manager of the Pearl Lake property, wished to btain some evidence of the value of the Pearl Lake claim efore he proceeded to install a large plant. He, therefore, ystematically prospected the ground with a diamond drill. No. 1 hole, which was put down vertically, and about the centre of the south claim, attained a depth of 800 feet. At 200 eet a small quartz stringer was encountered, but it carried o values. At 400 feet values were struck going up to $18.80. t must be noted that in every case maximum assays are given. While the management may guess at the average values, they express natural reluctance to strike a mean at this stage of the game. At 644 feet the main band of mineralized schist intersected with rich quartz stringers, was entered. From this oint down to 800 feet the drill cores showed more or less alues. Assays ranged as high as $58. No. 2 hole was put down 200 feet northeast of the initial boring. It was inclined at 76 deg. from the horizontal. The same small quartz stringer was struck and the upper band of mineralized schist was entered at 324 feet. Assays here ran up to $21.40. The second band of ore was struck at 520 feet, and the drill remained in the same formation as far down as 768 feet, values ceasing at 744 feet. Assays ran as high as $14. No. 3 hole is being put down in the southwest corner of the property. It will be continued to 1,200 feet. The ore bodies encountered are believed to be extensions of the Dixon system of veins, and it is calculated that on the Pearl Lake property they will vary from 67 to 120 feet of mineralized schist intersected by quartz stringers. Encouraged by the success of these operations, a main three-compartment shaft has already been commenced at the centre of the property. It will be sunk to 400 feet at once. A crosscut will be commenced from there, and the shaft will be taken to 600 feet. Stations will be cut and exploration commenced at every 200 feet, down to the 1,000-foot level, as quickly as possible. At the present time the Pearl Lake is running its drills with air from the McIntyre, but the big compressor is on the ground, and when the motor and transformer arrive, will be at once installed and work will commence on a large scale.

It is reported that the Seymour mine, operating in Larder Lake field, has ordered a small 10-stamp mill. The machinery, it is stated, is now on its way to the property, which lies on the Dane Road three miles from Larder Lake.

Spectacular ore is being obtained in the sinking of shafts on the Brydge claim in Tisdale, adjoining the Preston East Dome, and one claim south of the Dome. This claim has been purchased by Col, Stuart Weatherley, an Alaskan operator, who has called it the Little Pet Gold Mine. In a quartz porphyry formation, the gold is found freely in the wall rock, in a coarse state. A plant has been ordered for the property, air for one drill, and a hoist being supplied meantime from the Preston, and camp buildings are under construction.

The main shaft at the Swastika is now connected up with the 200-foot level. This will greatly facilitate the further development of the mine, and operations should now proceed at a much better pace. The new plant, lately installed, is working satisfactorily, and Manager Reddington is making an excellent daily record underground. There is no intention of building a mill other than the present small 5-stamp one, until considerably more ore has been blocked out.

Mr. C. E. Watson has resigned his position as manager of the Dobie Mining Company, in order that he may give his whole attention to the development of the Plenaurum. Some excellent results have been obtained this summer in the course of prospecting of the holdings of this Pearl Lake property. On its claims adjoining the Jupiter, the Plenaurum has discovered the Jupiter's veins, both on the surface and underground, with a diamond drill, an excellent showing has been made on the shore of Pearl Lake near Bewick-Moreing's No. 1 camp, and near the old Armstrong-Booth camps a very promising vein has been uncovered. About 100 yards from the Jupiter east line, No. 1 shaft is being sunk, and it will soon reach a depth of 100 feet. This shaft is sunk on an extension of the Jupiter vein, which for a width of 20 feet showed values of $20.90 to the ton. No. 2 shaft is being sunk on the edge of Pearl Lake near the Bewick-Moreing No. 1 camp. Mr. C. E. Watson has planned an extensive campaign of development, and once adequate power is obtained work will proceed very rapidly.

In addition to locating the rich Brydge lead on the Preston East Dome property, which will be reached by a crosscut from the No. 2 shaft, a spectacular showing has been uncovered on the north East Dome claim, just a short distance from the Dome line. In a dike of porphyry from 300 to 400 feet wide, many quartz stringers and seams exist, and free gold is found in these in a coarse state. The width of the paystreak has not yet been determined, and a large gang of men is engaged in stripping the vein. Cross-cutting westward at 90 feet in No. 2 shaft, a strong quartz vein 2 feet wide has been encountered, and eastward three parallel veins will be cut.

Work has been commenced by the Timmins-McMartin-Dunlap syndicate on the Dixon claim adjoining the McIntyre. The first few shots threw up some very spectacular ore and work is proceeding now with every confidence. The vein has been stripped for a distance of 900 feet and varies from 3 to 5 feet in width. In the railroad cut on the Dixon property, some beautiful specimens of quartz carrying much native gold have been found. The rock cut passes through the zone of mineralized schist, intersected by small quartz stringers, which in many cases are rich in native gold.

In the No. 4 shaft on the McIntyre at 180 feet, the vein has again been encountered. The vein left the shaft for about 80 feet, but has now dipped back again. Some very pretty specimens have been obtained.

Activity on the Standard Gold Mine has recently been confined to diamond drilling operations. Several thousand feet have been accomplished, it is reported, with satisfactory results. Nine buildings are being erected and everything got ready for an active winter campaign.

McIntyre Camp

The McEnaney is the first plant in Porcupine to be run by power from Sandy Falls, where the Porcupine Power Company has its station. The Porcupine Power Company has been prepared to deliver power since last July, but the fire has so retarded operations in the camp that no companies have been able to take advantage of it until recently.

A statement has been made to the effect that above the 200-foot level on the Rea, $280,000 in ore has been blocked out. At a depth of 250 feet the vein carries the same values, and sinking is now being carried on to the 300-foot level. At a distance of 175 feet west of the main shaft No. 2 shaft is being sunk.

BRITISH COLUMBIA.

At the date of writing (October 14) no settlement of the matters in dispute between the executive of District 18, United Mine Workers of America, and the Western Coal Operators' Association appears to have been reached. Mr. John P. White, International President of the U. M. W. of A., has returned to the United States, after having spent a week or more in the coal mining districts along the Crow's Nest Railway, from Lethbridge, Alberta, to Fernie, B.C. Mr. Lewis Stockett, chairman of the Operators' Association, spent the latter part of this week in Lethbridge, following the holding of a convention there of some delegates from all the locals of the district affected by the strike. While no official announcement has been made as to the actual point or points upon which no agreement seems to be practicable at this time, it is freely stated in conversation in some of the towns most directly affected by the long-continued cessation of coal mining that the most serious bar to a settlement is the insistence on the part of the U.M.W.A. local executive on the retention of the check-off system where it has been in existence in the past, and the most positive refusal of the Operators' Association to grant it at any mine concerned in the settlement sought to be arrived at. It should be remembered that this is only what is said in the various towns along the Crow's Nest Railway —it is not an authorized statement of either side to the dispute. It is quite probable, though, that the Operators' Association is fully determined to deny the Union this advantage; on the other hand, it is equally likely the Union officials will hold out for it as long as there shall remain the slightest chance of their retaining it to the extent they have enjoyed it in the past, for without it, there would be much difficulty in collecting fees, dues, fines, levies, etc., from many of the workers. It is also freely stated that both sides are willing to arrange for an early resumption of work on the basis of wh is known as the Gordon report—that is the report made to e Minister of Labour by the chairman of the Board of Conci tion that last summer heard much evidence bearing upon e various matters on which there had arisen divergence of op ion between workers and operators. There is a growing feel that the local officials of the U. M. W. of A. will not m longer be able to hold together the great body of the work in a determination not to return to work upon the terms Operators' Association is willing to concede. There are t strong influences at work tending to weaken the hold of Union officials on the men, namely, that 500 to 600 men already at work in various mines in the district, and that near approach of cold weather is bringing home to them fact that they will at least be very much inconvenienced, not caused positive suffering, by conditions which involve th being practically without money and without fuel. Doubtl the strike allowance made by the Union will keep them fr starving, but it is very probable their condition, if they sh not be earning wages regularly, will be a trying one.

It seems to me, therefore, and this with a sincere desire express an opinion without prejudice to the mine workers, th their sacrifice has been in vain, and that the Operators' As ciation is steadily gaining advantage, while the U. M. W. of is losing it.

Reviewing the position as it has during the last few da come under my notice, I find it to be about this: In the Brit Columbia part of the Crow's Nest district, the Crow's N Pass Coal Company has probably about 60 men doing devel ment only; it is not mining coal. I have no information c cerning Hosmer. At the Corbin mine, about 175 men are e ployed, more than half of them underground, and from 400 500 tons of coal a day is being shipped. In Alberta, there practically nothing being done at the mines of the Internatio and McGillivray Creek companies, at Coleman. The W Canadian Collieries, Ltd., is mining coal at its Blairmore mi employing 50 to 60 men, and shipping about 150 tons of coal day; but no production is being made at this company's B levue and Lille collieries. At Frank, the Canadian Coal Co solidated Company has men working, but how many and wh the production of coal I did not ascertain. The Leitch C lieries, Ltd., is mining a small quantity of coal at its Passbu (south) mine. At its north mine (known locally as at Poli Flats) much work has been in progress in connection with erection of a coal washery, coke ovens, and other surface i provements. In all, at least 100 men are employed by th company, which number, however, is only one-third of wh would be the working force under ordinary conditions. Co was being loaded on railway cars at both mines when the were visited this week. At Burmis, the Davenport Coal C is operating its mine, but with both number of men workin and output of coal below the ordinary. At Lundbreck tw companies are operating, but neither on a large scale. Aroun Lethbridge, no large mines are producing coal. One compan which has put in an extensive surface plant, is as yet onl doing development work underground, in the course of whic it takes out about 150 tons of coal a day, and this is bein shipped. Two small mines are together producing betwee 100 and 150 tons, which coal is sold for domestic use in Leth bridge. The present position is, therefore, that the large collieries are doing little work, and that little developmen work or surface improvements. It should be stated that sev eral of the smaller ones are working under agreements to pa whatever wages or rates shall eventually be agreed upon, whe the Operators' Association and the U. M. W. of A. shall ar rive at a settlement.

Similkameen.—In September the Hedley Gold Mining Com pany, owning and operating the Nickel Plate group of mine on Twenty-mile Creek, and the 40-stamp mill at Hedley, pai

nother dividend of five per cent. on its issued capital of $1,-0,000. This makes the third similar distribution of profits ring the current year, the total for the nine expired months which is $180,000. It is gratifying to know that not only the company's mining property continuing to look well the parts from which a comparatively large output of ore s long been maintained, but there have been late develop-nts in another part which are nnderstood to have added lly $1,000,000 worth of ore to the known reserves. About ree months ago ore of good grade was found in the lowest orkings, opened by what was known as Rodgers' tunnel, hich was practically abandoned by an earlier management unproductive, following the time when Mr. M. K. Rodgers d this adit driven and had satisfied himself that good ore ould be found here. So little was this part of the property nought of by a later manager that work in it was stopped, nd the tramway rails aloug the tunnel taken up. When, how-er, the property was acquired by the Hedley Gold Mining ompany, a different working policy was adopted by the pres-nt general superintendent, Mr. G. P. Jones, who agreed with Ir. Rodgers concerning the prospective value of the lowest orkings and proceeded to extend them. Since a shoot of good re was entered, it has been developed and found to be 46 eet in width, while about 150 feet of drifting has been done n it, with the result that, as above-mentioned, a substantial ddition has been made to the available ore reserves. This ewly-opened orebody is well up to standard grade; indeed, it understood that some of the ore contains gold to the value f $15 to $20 per ton. It is manifest, therefore, that the com-any will not experience any trouble in maintaining the aver-ge grade of its milling ore at the customary value of about 12 per ton.

Observatory Inlet—The Pacific Metals Company, Ltd., of hich Mr. J. L. Parker is general manager, a short time ago eceived advice from its mine foreman at the Red Wiug mine, ituated in the vicinity of Goose Bay, Observatory Inlet, that e had broken into more ore in the workings, the orebody aving widened from about 6 feet to between 10 and 11 feet. he additional width of ore was described as being "fine re." There had been encouutered a cross lens of ore run-ing at right angles to the vein. This cross lens is now being leveloped by driving on the ore west of the dike and towards he footwall. The assay value of a sample of this orebody, aken over a width of 6 feet, showed as follows: copper, 6.75 per cent.; silver, 4.45 oz., and gold, 9.06 oz. per ton. This is the third cross orebody found in the length of the tunnel so far driven. An average sample of 6 feet of ore on the strike of the vein assayed: copper, 4.12 per cent; silver, 2.35 oz., and gold, 0.02 oz. per ton. The estimated recoverable value of this ore, after allowing for the customary smelting deductions, is placed at $7.70 per ton. Allowing for mining costs, $1.50; smelting, $2; and freight, $1.50 per ton, there would remain an estimated net profit of $2.70 per ton.

Vancouver Island.—Although the Tyee Copper Company's last fiscal year ended April 30, 1911, no information concerning the quantity of ore smelted in that year at its smeltery at Ladysmith, Vancouver Island, and the amount and value of the product, had up to October been published. The figures follow and, for purposes of comparison, also those of the company's two immediately preceding fiscal years:

YEAR ENDED APRIL, 1911.

	Tons.
Ore received at Ladysmith smeltery ...	46,521
Ore smelted at Ladysmith smeltery	44,817
Total value, less refining charges only	$555,843.08
Total quantity of copper produced	4,242,246 lbs.

Corresponding figures for fiscal year ended April 30, 1910:

	Tons.
Ore received	41,530
Ore smelted	45,758
Total value, less refining charges only	$575,468
Total quantity of copper produced	3,461,107 lbs.

Corresponding figures for fiscal year ended April 30, 1909:

	Tons.
Ore received	34,304
Ore smelted	29,550
Total value, less refining charges only...	$327,270
Total quantity of copper produced	2,216,230 lbs.

It will be noted that the quantity of copper produced last year was 781,139 lbs. greater than in the year to April 30, 1910, and 2,026,016 lbs. greater than in the year to April 30, 1909, the latter being an increase of nearly 100 per cent. The management of the Tyee Copper Company may be congratulated on the progress made, especially as this was in the face of keen competition for custom ores and low average market prices for copper.

GENERAL MINING NEWS.

NOVA SCOTIA.

Sydney, Oct. 20.—President Plummer and the visiting direc-ors of the Dominion Steel and Coal Company, spent the day t Glace Bay and the various collieries of the company, and re-urned to Sydney this evening. When seen to-day Mr. Plum-ner and the directors expressed themselves as thoroughly satis-ied with the progress of the development work now under way t the mines, and conditions geuerally at their Cape Breton ndustries.

The directors were particularly struck with the great pro-gress and development of the New Waterford district, where the ompany anticipate having at least from four to six new ollieries producing coal by next summer. It is estimated that hat total output from the mines of the company will exceed 4,000,000 tons and that there will also be a substantial in-rease in shipments.

The president and directors were accompanied by General Manager M. J. J. Butler, D. H. McDougall, Assistant Gen-eral Manager, and C. S. Cameron, Comptroller of the Steel Company on tour of the collieries to-day.

The directors leave to-night for Montreal, only President Plummer remaining in the city for a few days to attend to important business which has piled up here.

As the result of an expressed desire on the part of Mr. Plummer on behalf of the company, the city will probably undertake the erection of a new hospital for the accommodation of city patients shortly, the present institution which is conducted by the company being entirely inadeqnate to supply the ever increasing number of patients seeking admission.

About twenty Italians who have been residing here for the past several years, left here yesterday en route for Italy with the intention of engaging in the present Turko-Italian war. They are believed to be the first party of Italians from the Maritime provinces to start for the scene of hostilities.

Halifax, October 17.—President Plummer and ten directors of the Dominion Steel Corporation, leave Montreal for Sydney, on October 17th, and will spend four days inspecting the steel plant and mines, leaving again Sunday night.

W. B. Perley, assistant to the president of the U. S. Steel Corporation, is in Sydney, but it is not known that his visit has any grave significance.

The directors' party consists of President Plummer, Sir H. Montagu Allan, Messrs. Gei. Caverhill, Wm. McMaster, Frederic Nicholls, W. G. Ross, J. R. Wilson, and Mark Workman, accompanied by Mr. Cameron, secretary of the company, and Mr. J. P. McNaughton, general sales agent. They leave at 7.30 to-night by the I. C. R.

Sydney, October 15.—The Dominion Coal Company has started the work of opening another new colliery at Lingan, near the scene of the mining operations conducted there about 30 years ago. It is not definitely known as yet when the new mine will be in a position to furnish a coal output, but the preliminary work will be started as soon as possible. It is the intention of the company to ship their entire output next year from Lingan direct. For this purpose the company will erect a new pier there and equip it with the most modern conveniences for the handling of coal and loading their steamers and vessels with as little delay as possible. The company is erecting a new bankhead at No. 15 colliery at Waterford and several large colliery buildings, which will be ready for business early next winter.

ONTARIO.

Cobalt, Oct. 16.—For the past year the McKinley-Darragh Company has had four drills at work on practically nothing but crosscuts on the Savage lot, and in that time vast changes have been made in the underground workings by the opening up of new veins.

One of the latest discoveries is No. 8, found some six weeks ago from No. 4 shaft. This vein runs along the foot of Diabase Mountain and the 150 feet of drifting that has been done has revealed a vein averaging two inches in width. The ore had been very patchy, some times being exceptionally high-grade, while in other parts it would be comparatively lean.

Kenora, October 18.—The Cameron Island mine, on Shoal Lake, about 35 miles southwest of here, is to be re-opened and developed.

B. M. Cameron, of Hamilton, and Frank Grew, of Toronto, representing a syndicate that recently purchased the property, have decided to put the plant into shape this winter and start actual mining early in the spring.

Cobalt.—Beaver directors, who have for some time been contemplating the erection of a concentrator to treat the low grade ore piling up on the Beaver dump, have finally decided to begin construction, and ground is being broken for this purpose. The mill will be constructed to treat fifty tons per day, and will be so designed that it can easily be increased if circumstances warrant the extension.

It is not expected that the construction of the mill will interfere with Beaver dividends. The mill will probably cost from $30,000 to $40,000, but the company had on August 31 last nearly $60,000 in cash, and twice that amount coming to them from the smelters for ore shipped.

BRITISH COLUMBIA.

Ymir, October 19.—About noon yesterday fire was seen by the caretaker of the Ymir mine issuing from one of the buildings of the mine. He, at the time, was at the mill, about a half mile away. On arriving at the scene, all of the buildings were discovered to be on fire, and, being alone, and with the hose in one of the buildings, he could do little towards checking its progress.

The following buildings were totally destroyed: Blacksmith shop, cook house, dining house, two store rooms, boiler house, two cottages, and stables. The aerial tramway terminal building was saved by carrying water from the pipe line, but the rest of the buildings, together with various mining t[o]ls, stores and other etcetera, were a total loss. The cause of the fire is at present unknown.

Loss is estimated at about $20,000, which was partly cov[e]red by insurance.

Vancouver, B.C.—Mr. A. C. Flumerfeldt, of Victoria, has this week elected a member of the board of directors of G[ra]nby Consolidated Mining & Smelting Company, of Grand F[or]ks and Phoenix. He will once more be in touch with its affairs [in] which he formerly took a prominent part. For several y[ea]rs he filled the important position of assistant to the presid[en]t, an office then filled by the late S. H. C. Miner, of Gran[by], Que., and resided at Grand Forks.

When Mr. Miner withdrew from the office, Mr. Flumerf[eldt] also resigned. Although Mr. Miner was credited with hav[ing] sold most of his stock in the big company, it developed a[fter] his death that he was the second largest shareholder. [Mr.] Flumerfeldt is executor of the estate of the deceased milli[on]aire.

Vancouver, October 24.—Mining properties in the fam[ous] Silver Lead section, Slocan district, valued at over $2,000,[000] were amalgamated by a deal concluded in Vancouver to-day.

The amalgamation is one of the most important moves m[ade] in British Columbia mining affairs for several years. It is [the] consolidation under a new company of the Byron, N. W., [and] John M. Harris mineral properties at Sandon, most noted [of] which is the Slocan Star mine, which, up to the time w[hen] its activities were suspended by litigation, had produced [$]-000,000 in silver, lead, and zinc.

UNITED STATES.

Butte, Mont.—The copper production of this district [for] the month of September was 1,200,000 pounds less than it [was] in August, as the following official figures of the Anacon[da] Company will show: Washoe smelter, 15,900,000 pounds; Gr[eat] Falls, 5,400,000 pounds; making a total of 21,300,000 poun[ds], the East Butte smelter turned out 1,000,000 pounds, bringi[ng] the grand total for the district up to 22,300,000 pounds, [as] compared with 23,500,000 pounds in August.

Miami, Ariz., Oct. 20.—At the Miami all departments [are] running with a smoothness that is remarkable for a mine th[at] is in its initial stages of operation. General Manager B. Gottsberger states that from 1,800 to 1,900 tons of ore p[er] day are being mined and milled, with a daily production [of] about 82 tons of concentrates averaging 41 to 42 per ce[nt] copper.

Cripple Creek, Colo., Oct. 20.—Checks have been mailed o[ut] for the regular quarterly dividend of 2 cents a share by t[he] Portland Gold Mining Company. The new mill at the Portla[nd] mine treated 29,559 tons of low-grade ore during the thr[ee] months ending September 30th, at a net profit of $33,110.7[1], according to a statement accompanying the dividend check. The total net profit of the company from the mill during th[e] first nine months of this year was $100,939.16.

Duluth, Minn., Oct. 23.—The ore rate on the two Iron Rang[e] roads of the United States Steel Corporation will be cut [to] 60 cents a gross ton within the next 30 or 40 days. The a[n]nouncement of the proposed reduction came to-day from Pres[i]dent William A. McGonagle, of the Duluth, Mesaba, and No[r]thern Railway, later confirmed by President Frank E. Hou[ston] of the Duluth and Iron Range Railway.

The present rate on iron ore is 80 cents per gross ton fro[m] all Mesaba range points to Duluth. The rate covers all shi[p]ping points on the Duluth, Mesaba, and Northern Road and a[ll] the Mesaba range points on the Duluth and Iron Range Ra[il]road. From Tower the rate is 90 cents to the docks at Tw[o] Harbours, and from Ely it is $1.

STATISTICS AND RETURNS

COBALT ORE SHIPMENTS.

Following are the shipments from the Cobalt camp for the week ending October 20th, and those from Jan. 1, 1911, to date:

	Oct. 20. Ore in lbs.	Since Jan 1. Ore in lbs.
Badger	.....	55,200
Bailey	.....	40,000
Barber	.....	6,000
Beaver	64,479	1,465,937
Buffalo	62,427	2,154,971
Chambers-Ferland	.....	1,086,900
City of Cobalt	.....	663,980
Cobalt Lake	64,700	3,585,090
Cobalt Townsite	104,000	1,089,420
Colonial	.....	183,410
Coniagas	125,390	3,442,153
Crown Reserve	61,200	1,951,980
Drummond	120,000	2,622,480
Green-Meehan	.....	60,000
Hargraves	.....	161,100
Hudson Bay	.....	1,194,340
Kerr Lake	60,070	2,173,670
King Edward	.....	40,000
La Rose	66,500	6,023,078
McKinley Darragh	175,089	5,334,438
Nipissing	127,649	4,876,667
O'Brien	63,800	1,210,958
O'Brien, M. J.	.....	47,000
Peterson Lake, Little Nip.	.....	58,430
Provincial	.....	151,950
Right of Way	59,800	1.191,805
Silver Cliff	.....	106,680
Standard	.....	102,813
Temiskaming	.....	1,348,452
Trethewey	53,040	1,118,020
Wettlaufer	.....	117,232

The shipments for the week were 1,208,140 pounds, or 604 tons, against 580 tons last week.

The shipments from Jan. 1, to Oct. 20, were 42,361,798 lbs.. or 21,180 tons.

B. C. ORE SHIPMENTS.

The ore shipments for the week ending October 14th totalled 1085 tons, and the smelter receipts were 14,704 tons. For the year to date the shipments were 1,302,545 tons, and the receipts were 1,175,036 tons. Following are the returns:

Rossland Shipments.

Centre Star	3,699	157,709
Le Roi No. 2	463	22,414
Le Roi No. 2, milled	300	12,300
Le Roi	531	12,926
Other mines	.....	457
Total	4,993	205,806

Boundary Shipments.

Mother Lode	4,600	243,583
Rawhide	3,327	33,446
Jackpot	331	21,416
Athelstan	198	6,614
Unnamed	690	5,813
Other mines	.....	630,692
Total	9,146	941,564

Slocan-Kootenay Shipments.

Molly Gibson	31	860
Van Roi, milled	800	30,649
Molly Gibson, milled	300	39,000
Sullivan	247	15,481
St. Eugene, milled	420	21,876
Richmond-Eureka	58	1,879
Silver Cup	31	414
Rambler-Cariboo	60	1,387
Queen, milled	420	17,010
Granite-Poorman, milled	250	10,260
Nugget, milled	110	4,510
Second Relief	25	108

Total	5,558	263,099

DOMINION STEEL.

The Dominion Steel Company's output for September was as follows:

Pig iron, 22,300 tons; steel ingots, 27,290; blooming, 23,705; rails, 16,575; rods, 3,365; coke, 39,300. Total shipments, 22,000.

The rod mill is on a single shift.

TORONTO MARKETS.

October 26.—(Quotations from Canada Metal Co. Toronto):

Spelter, 6.50 cents per pound.
Lead, 4.25 cents per pound.
Antimony, 7 to 9 cents per pound.
Tin, 43 cents per pound.
Copper, casting, 12.85 cents per pound.
Electrolytic, 12.85 cents per pound.

Ingot brass, 7 to 12 cents per pound.

October 26.—Pig Iron (Quotations from Drummond, McCall and Co., Toronto):

Summerlee No. 1, $23.00 (f.o.b. Toronto).
Summerlee No. 2, $22.50 (f.o.b. Toronto).
Midland No. 1, $19.00 (f.o.b. Toronto).
Midland No. 2, $18.50 (f.o.b. Toronto).

GENERAL MARKETS.

Coal, anthracite, $5.50 to $6.75.
Coal, bituminous, $3.50 to $4.50 for 1¼-inch lump.

Coke.

October 24.—Connellsville Coke (f.o.b. ovens):
Furnace Coke, prompt, $1.50 to $1.55 per ton.
Foundry Coke, prompt, $1.80 to $1.90 per ton.

October 24.—Tin, Straits, 42.00 cents.
Copper, Prime Lake, 12.50 cents.
Electrolytic Copper, 12.50 cents.
Copper wire, 13.50 cents.
Lead, 4.25 to 4.35 cents.
Spelter, 6.30 cents.

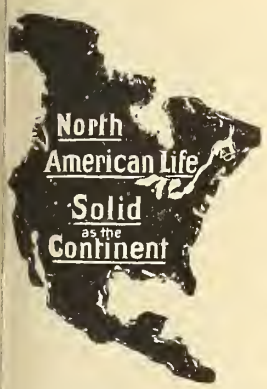
GENERATORS and MOTORS FOR ALL PURPOSES



A Man's Value

to his family or those dependent upon him is measured by his earning capacity. As death entails the loss of that earning capacity, every man should make provision for his loved ones in order to make good to them the financial loss that would ensue. This is the purpose of life insurance, and no man is blameless whose life is not insured.

It makes no Difference

whether you mill, smelt or ship your ores you must have assays and analyses of unquestionable accuracy reported to you in the shortest possible time. Our equipment is especially designed to meet these requirements.

WE also test ores in a practical way to determine just what metallurgical process is best adapted to it to secure the highest commercial results. Write us for prices for your particular problem.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

DEPARTMENT OF MINES. GEOLOGICAL SURVEY.

PUBLICATIONS

The Geological Survey has published maps and reports dealing wit a large part of Canada, with many local areas and special subject

A catalogue of publications will be sent free to any applicant. A single copy of a map or report that is specially desired will sent to a Canadian applicant free of cost and to others at a nominal price. The applicant should state definitely the precise area co cerning which information is desired, and it is often of assistance in filling an order for a map or report if he states the use for whi it is required.

Most of the older reports are out of print, but they may usually be found in public libraries, libraries of the Canadian Mini Institute, etc.

REPORTS RECENTLY ISSUED:

CANADA

1085. Descriptive Sketch of the Geology and Economic Minerals of Canada. Accompanied by a geological and mineral map Canada, by G. A. Young and R. W. Brock.
1170. Summary Report of the Geological Survey for 1910.

NEW BRUNSWICK and NOVA SCOTIA

1113. Memoir No. 16. The Clay and Shale Deposits of Nova Scotia and portions of New Brunswick, by H. Ries aud J. Keele.

QUEBEC

1110. Memoir No. 4. Geological reconnaissance along the line of the National Transcontinental Railway in Western Quebec, W. J. Wilson, accompanied by a map.

1135. Map 15A. Phoenix, British Columbia, topographical. Scale 400 ft. to 1 inch.
1148. Map 20A. Victoria sheet, Vancouver Island, B.C., topographical. Scale 1 mile to 1 inch.
1149. Map 21A. Saanich sheet, Vancouver Island, B.C., topographical. Scale 1 mile to 1 inch.
1164. Map 28 A. Sketch map of Portland Canal Mining District.

YUKON and NORTH WEST TERRITORIES

1089. Map 9A. Explored Routes on Parts of the Albany, Severn and Winisk Rivers. Scale 8 miles to 1 inch.

NOTE.—Maps published within the last two years may be had, printed on linen for field use. A charge of cents is made for maps on linen.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and econon geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature r ported upon. Letters and samples that are of a Departmental nature, addressed to the Director may be mailed O.H.M.S. free of posta

Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.

BRITISH COLUMBIA

The Mineral Province of Western Canada

Its produced Minerals valued as follows: Placer Gold, $71,213,103; Lode Gold, $60,811,067; Silver, $31,095,602; Lead, $24,645,605; Copper, $60,743,405; Other Metals (Iron, Zinc, etc.), $1,083,172; Coal and Coke, $114,012,596: Building Stone, Brick, etc., $10,593,100; making its Mineral Production at the end of 1910 show an

Aggregate Value of $374,197,650.

In 1910 the quantity of Ore mined was 2,216,428 tons, and of coal 3,139,235 long tons. The value of Minerals produced that year was: Placer Gold, $540,000; Lode Gold, $5,533,386; Silver, $1,245,016; Lead, $1,386,350; Copper, $4,871,512; Coal and Coke, $11,108,335; Other Minerals, $1,692,473, making the

Total Value for 1910, $26,377,066.

Lode mining has only been in progress for about eighteen years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those in any other Province in the Dominion, or any Colony in the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with mining Reports and Maps, may be obtained gratis by addressing

Province of Quebec

Department of Colonization, Mines, and Fisheries.

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, Etc.

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

MINERS' CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. Th price of this certificate is $10.00 and it is valid until the first of January following. This certificate gives the right to prospect o public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to th extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his right must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cent an acre per year and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidav that during the year work has been performed to the extent of at least twenty-five days labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $10 an acre fo SUPERIOR METALS when more than 20 miles distant from a railway and $20 an acre when less than 20 miles.

For INFERIOR METALS the prices are $2.00 and $4.00 an acre respectively.

The attention of prospectors is specially called to the territory in the North-Western part of the province of Quebec, north of th height of land, where important mineralized belts are known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY 228 ST. DENIS STREET, MONTREAL, for the determination, assays and analysis of minerals at very reduced rates for the benefit o miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensur results of undoubted integrity and reliability.

The Bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of th Province, on application addressed to

THE HONORABLE THE MINISTER OF COLONIZATION, MINES, AND FISHERIES, QUEBEC.

Nova Scotia Mines

Gold, Coal, Iron, Copper, Lead, Tin, Manganese, Tungsten, and other minerals.

The Gold District covers more than three thousand square miles. Millions of dollars worth of gold have been taken from the gold fields of Nova Scotia and millions of dollar's worth remain for recovery.

Gold mining in this Province offers good inducement for investment. Labor is cheap and plentiful: timber and fuel are abundant.

Large deposits of iron also are known to exist at various places in the Province; and considerable mining has been done in connection with this mineral, the ore being used locally and shipped to foreign ports.

Among the most important minerals occurring in economic quantities may be mentioned, Coal, Gold, Silver, Manganese, Leadsilver, Copper, Barytes, Mineral Pigments, Gypsum and Tungsten.

Licenses are issued for prospecting for Gold and Silver for a term of twelve months. The licenses are for areas 150 by 250 feet, and can be obtained for 50c. an area.

Leases can be secured for $2. an area, for a term of forty years; subject to annual rental of 50c. an area.

Licenses to search over five square miles, for a period of eighteen months, for minerals other than gold and silver, cost $30.

Leases for three renewable terms of twenty years each can be obtained for $50., and are subject to a yearly rental of $30.

Royalties are as follows:—

Gold, two per cent on the gross value thereof; Copper, four cents a unit; Lead, two cents a unit; Iron, five cents a ton; Tin and Precious Stones, five per cent; Coal, ten cents on every long ton sold or removed from the mine.

Copies of the mining law can be had gratis, by applying to the Department of Public Works and Mines, Halifax, Nova Scotia, or to Mr. John Howard, Agent General for Nova Scotia, 57a Pall Mall, London, England.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. W. H. HURST,
Minister of Lands, Forests and Mines,
Toronto, Canada.

WANTED

AGENCY FOR ORES AND MINERALS.

An Ore Merchant who has connections with all the blast-furnaces and electro-metallurgical firms of France desires to communicate directly with firms who produce or sell:—

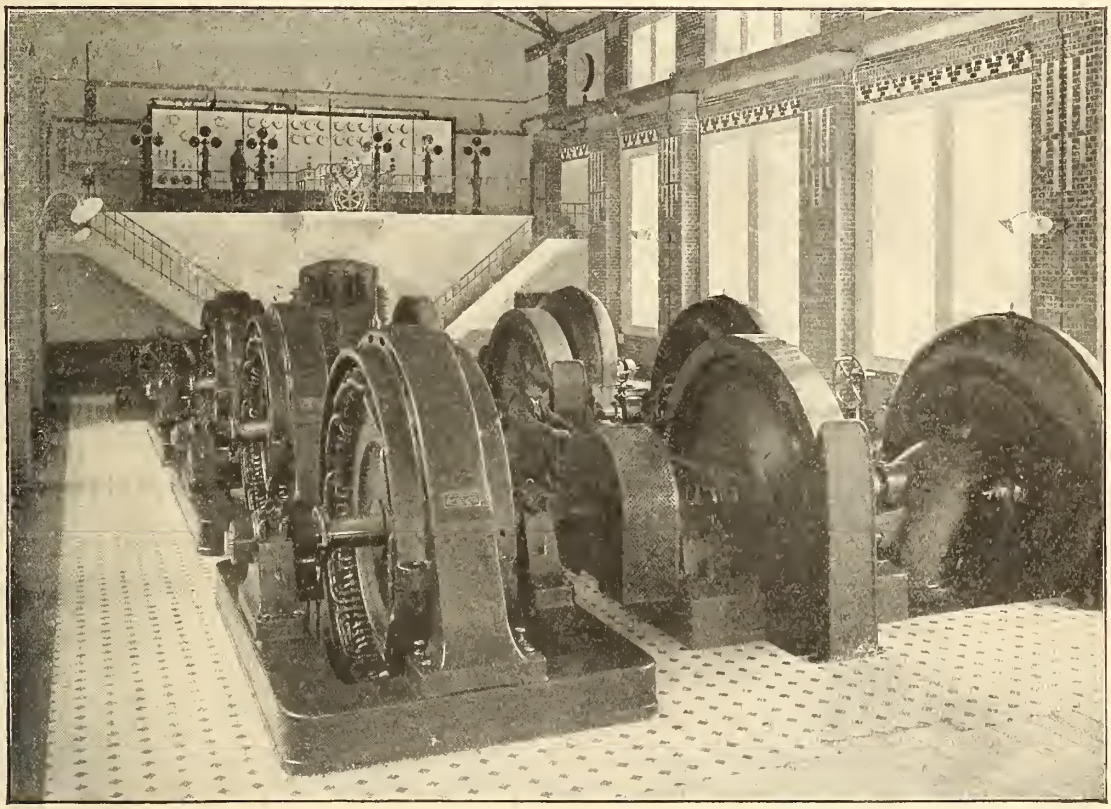
Chrome Ore; India, Brazil, or Caucasus Manganese Ores; Graphite; Tungsten Ores; Molybdenite Antimony Ores; Iron Ores; and Asbestos.

It is desired to purchase Ores outright, or to take over Sales.

AGENCY FOR FRANCE:—

Address—Mr. Ch. CHAUTEN,
123 Rue Lamark, PARIS.

SIEMENS



3 of 5 Siemens Horizontal Water Wheel type Generators each 715 h.p.

The Siemens Companies manufacture horizontal and vertical water wheel generators and have a great number of both types in successful operation in all parts of the world with outputs up to 16,000 h.p. and pressures up to 20,000 Volts. More than **50** machines with terminal pressure of **10,000 Volts** and over have been constructed.

THE "ROYAL LINE"

To Europe in

Less than Four Days

LAND TO LAND

The St. Lawrence Route to Europe by the ROYAL LINE shortens the ocean voyage to less than four days, and affords the traveller two days of delightful, sheltered sailing down the great St. Lawrence with its never ending panorama of beautiful scenery and historically famous points. The splendid triple turbine steamers

ROYAL GEORGE and ROYAL EDWARD

hold all speed records and afford the most luxurious accommodation in the Canadian-European service. The English Port, Bristol, is only two hour's run to London by the special boat trains which meet the Royal Line Steamers on arrival.

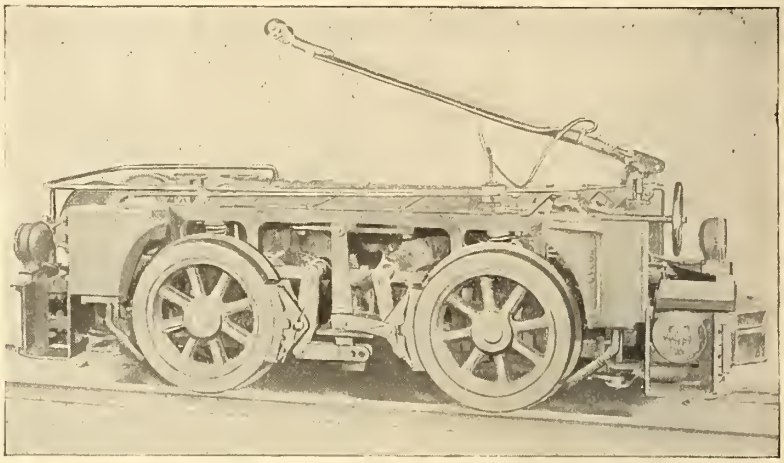
Baldwin-Westinghouse Mine Locomotives

Figure how much animal haulage costs you a month, feeding, shoeing, and the pay of drivers, then let us tell you how much less it costs to maintain Baldwin-Westinghouse Mine Locomotives to do the same work better.



Baldwin-Westinghouse Electric Gathering Locomotive

You never hear of a mine going back to animal haulage after having once used Baldwin-Westinghouse Mine Locomotives. The contrast is too great all along the line; in efficiency, cleanliness and economy of maintenance. We can give you some figures as to the savings effected by electric mine haulage that will appeal to you.

KINGSTON, ONT.

MINING & SCIENTIFIC PRESS

Controlled by T. A. Rickard | **Established 1860** | **H. Foster Bain, Editor** | **Published weekly** | **Thomas T. Read, Associate Editor**

In every issue valuable articles are published on mining, metallurgy, and geology, the latest news from special correspondents at the principal mining centers, letters giving the ideas and experience of successful men, and other items of useful knowledge.

THE MINING MAGAZINE

Established September, 1909

T. A. RICKARD, Editor — **Published monthly at London, England**

A monthly magazine is the natural corollary of a technical weekly. It permits of more deliberate and more extended notice of matters concerning which the news element is less important.

The Mining Magazine includes a review of the world's progress in mining, metallurgy, and economic geology, written by men who have personal knowledge of the regions and conditions discussed.

A LETTER TO YOU

SUBJECT: LOWER STOPING COSTS

"We have tried Sullivan Stopers in competition with the other leading makes of hammer drills. We have found that Sullivan Stopers cost us less per foot of hole drilled, or per yard of rock taken out." "They are very rapid drillers, but take less air and fewer repairs than our other stopers."

"We have learned that our bill for broken drill bits is smaller on Sullivan Stopers, and that they are more popular with our men, because they rotate easier, run in better balance and have less jar and vibration than any of the other stopers we have tried."

"We shall buy Sullivan Stopers exclusively after this."

This letter was written in our own office. It is a composite letter—the opinion of mining companies in all parts of the United States, Canada, and Mexico, as reported direct to us and backed by repeated purchases of DA-21 Sullivan Stopers.

Write any of our offices for the names of these concerns and details of their experiments; or better still, ask for one or more drills for a free trial in your own mine.

Write for new Bulletin 666-C

Amatite ROOFING

FOR MINE BUILDINGS

AMATITE is exactly suited to mining buildings because:

1—It can be laid by unskilled labor.

2—It has a real mineral surface *which requires no painting.*

3—Its cost is lower than that of other ready roofings of less weight.

4—It comes in rolls ready to be unrolled on the roof and nailed down.

5—The necessary nails and cement are supplied free, packed handily in the centre of each roll.

The mineral surface of Amatite is somewhat of a novelty: and the fact that it obviates the old painting nuisance, is giving to this roofing the leadership of the ready roofing industry.

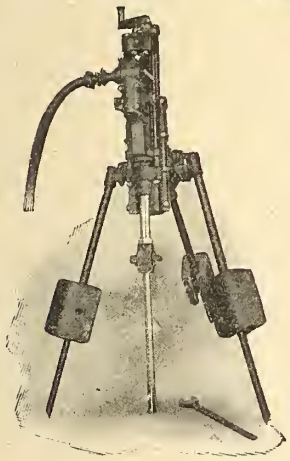
The surface consists of mineral particles embedded under great pressure into a tough plastic matrix of pitch.

A sample of Amatite will be sent free on request.

The Paterson Mfg. Co., Ltd., Montreal, Toronto Winnipeg, Vancouver, St. John, N B. Halifax, N. S.

"LITTLE GIANT"

ROCK DRILLS



Rock Drill economy is based on the cost per foot of hole drilled not on the cost per day, week, or month of each drill.

The powerful crushing blow of the Little Giant is a guarantee of the greatest footage per drill at the lowest cost per foot of hole.

The workmanship and material in "Little Giant" Drills are the best obtainable and each part is made consistent with its duties.

The "Little Giant" is the product of a vast experience in rock drill manufacturing.

ANNOUNCEMENT

THE CANADIAN MINING JOURNAL'S

PORCUPINE SERIES

VOLUME I.

A SERIES OF UNIQUE ILLUSTRATED ARTICLES.

Accompanied by a Complete Geological Map and Claim Maps of the Various Townships

The Publishers of THE CANADIAN MINING JOURNAL, in view of the fact that the demand for back numbers containing articles on Porcupine cannot be met, are bringing out a book embodying descriptive, geological, and general data relating to Porcupine. The latest available township maps and a large Geological Map will be included. The object of the publishers is to present in compact form a book that will guide the investor, the engineer, and the general reader.

The book will be on sale within a few days.

The price is $2.00 per volume. For orders of more than ten volumes a reduction of ten per cent. will be made. The edition is limited.

MONTREAL.

Why the C.P.R. North Toronto Route to Ottawa and Montreal is the Logical One

The train leaves as follows:

Leave North Parkdale - - -	9.15 p.m.	Leave West Toronto - - - -	9.30 p.m.
Arrive North Toronto - - -	9.40 p.m.	Leave North Toronto - - -	10.00 p.m.
Arrive Ottawa, 6.50 a.m.		Arrive Montreal, 7.00 a.m.	
Daily.		Double Electric Berth Lights.	

¶ The residents of Toronto are adjacent to either North Parkdale, West Toronto or North Toronto stations, same being easily accessible and close to residential districts.

¶ The North Toronto route is over an hour faster and overcomes a long hill climb for the train out of Toronto obviating any inconvenience and ensuring early arrival at Montreal and Ottawa.

¶ The roadbed has been improved till it is unexcelled in Canada. Practically half the line is double tracked.

¶ The equipment is "Canadian Pacific Standard," a synonym for the "best" and attentive porters, ensure efficient service.

Arranged in three sections—

Australasian, African, Miscellaneous,

Preceded by Tables of Crushings and followed by lists of Mining

DIRECTORS, SECRETARIES, MINING and CONSULTING ENGINEERS and MINE MANAGERS.

Their Names, Addresses, and Descriptions, and Names of the Companies with which they are connected, and a

DICTIONARY OF MINING AND OTHER TERMS.

THE MINING MANUAL for 1910 contains particulars of over 3,120 Companies arranged in three sections, 315 Companies being AUSTRALASIAN (including Western Australia, Queensland, Broken Hill, Deep Leads, New Zealand and Tasmania); 985 AFRICAN (including Transvaal, Rhodesia, Cape Colony, Natal, West Africa, Nigeria, &c.); and 1,820 MISCELLANEOUS (including Mexico, India, America, Europe, Siberia, &c., and the Coal, Iron, Tin and other Mining concerns of the United Kingdom). The particulars given of each Company include the Directors and other officials; date of establishment; seat of operations; description of the property, with the purchase consideration; plant erected or in course of erection; present working results; ore reserves; details of capital; calls; dividends paid; and the financial position as disclosed by the accounts. Highest and lowest prices of the shares for the last four years, also latest price.

The Index, which forms a highly important feature of the book, contains the names of over 5,300 Companies, consequently active, private or dormant companies can easily be traced.

Crushing tables and Gold Outputs from the principal mines are given at the commencement of the volume, showing tons treated monthly, results obtained, and yield per ton; also annual yields.

Lists of Directors (8,000), Secretaries (1,900, Mining and Consulting Engineers and Mine Managers (1,400) include their addresses and descriptions and names of the Companies with which they are connected.

To be obtained from all Booksellers, or direct from the Proprietor,

of to-day is the result of years of experiments and improvements. It represents the highest development in design and equipment ever offered to the users of mining locomotives, and is one of the determining factors in mining production.

JEFFREY LOCOMOTIVES are built to meet almost every possible condition of service. They are constructed throughout of the best material, a careful analysis being made of every piece of raw material that enters into their composition and all parts rigidly inspected and tested before and after assembling.

We design and build complete Coal Mine and Tipple Equipments, including Coal Cutters, Drills, Car Hauls, Coal Washeries, Elevators, Scraper and Pivoted Bucket Conveyers, Screens, Crushers, Larries, Mine Fans, Cages, Cross-Over Dumps, etc.

THE NATIONAL MINE SAFETY DEMONSTRATION.

When the final history of social evolution is written, the first decade of the twentieth century will be noted as remarkable for the expansion of humanitarian movements.

Of all industries, that of mining has had to bear the obloquy of having the largest fatality rate. This damaging public belief is not founded on fact. The rate of casualties per one thousand men employed is higher in both the railroad business, and in the structural steel trade.

It is gratifying to know that in no industry other than mining is such radical action being taken to correct and control conditions that make for high fatality rates. In European countries, particularly in Germany, the government authorities have made it obligatory upon mine operators to provide amply for the comfort, moral well-being, health, and safety of the miner. Canada and the United States have fallen far short of the standard set by trans-Atlantic countries. So far as corporations are concerned, it is probable that among the coal mining companies the credit of the first systematic use of breathing-apparatus belongs to the Dominion Coal Company. Somewhat over four years ago that company established at Glace Bay a completely equipped life-saving station.

It remained, however, for the United States Government to take the initiative as a government. Last year, after the Technologie Branch of the Geological Survey had been organized as the Bureau of Mines, under the direction of Dr. J. A. Holmes, there was begun a national movement the object of which was to educate the miner in the use of first-aid methods and of breathing apparatus. Seven special cars were secured to cover the more important mining fields. These cars are used not only for demonstration purposes, but also for actual rescue work. Stations were established at various points, the large grounds of the United States Arsenal, an establishment dating back to 1814, being adapted at Pittsburgh.

Pittsburgh was chosen as the scene of the late National Mine Safety Demonstration. No better place could have been selected, nor could the time have been more opportune. Pittsburgh is the centre of a large mining population. The second day of the Demonstration, coincided with the Centennial Celebration of the introduction of steam navigation on the Ohio River. The presence of President Taft and of members of his Cabinet lent eclat to the occasion.

Our readers will be given in another issue of the CANADIAN MINING JOURNAL a full account of the pro-

ceedings at the Demonstration. It suffices here to accentuate the lessons that were there illustrated.

The vivid and spectacular experiments showing the danger of using any but permissible explosives in the presence of coal dust were exceedingly impressive. No one who was present at the belated explosion at the Bureau's Experimental Mine will easily forget the tremendous detonation and the huge volume of flame that resulted. Impressive also was the series of experiments at Forbes Field, and at the Arsenal. The first-aid competition at the former place was a wonderful exemplification of what training will effect. Working miners displayed a degree of skill and facility only to be expected from experienced surgeons. And, as the hundreds of competitors were selected from other thousands, the competition was doubly inspiring.

In these columns have been published many articles referring to the use of rescue apparatus in coal mines. The necessity of this work need not again be emphasized. Rather is it timely to allude to the wider application of certain newer devices.

A quite mistaken idea prevails as to the scope of the breathing-apparatus. Whilst it is quite true that in coal mines the breathing-helmet has been principally used, it is equally true that its value in the metal mine is being more and more appreciated. For instance, in fighting timber fires in large mines there is no question as to the utility of the helmet. This has been proven many a time in the last year in the western States. In fact, many metal mining companies have established trained corps within and without their mines.

First-aid is part and parcel of the work. To be able to meet emergencies it is essential that the rescue party be equipped with a knowledge of the methods of resuscitation, of dressing wounds, and of reducing fractures.

But especially to be noticed is the latest application of compressed oxygen. In many cases of gas poisoning the victim is beyond resuscitation by ordinary means. Although a feeble spark of life may be observable, artificial respiration fails to do its part. It is here that the ingenuity of the inventor has come to the aid of humanity. The pulmotor, a contrivance as simple as it is ingenious, actually performs the function of breathing for the subject who is too far gone to inhale and exhale the oxygen himself. The average sufferer from gas poisoning will respond to this treatment in a very few minutes. Whenever there is a sign of vitality there is hope. Cases that defy all other means are amenable to the pulmotor. A full discussion of the use of the instrument, written by Mr. E. T. Corkill, will be found on another page.

* * * *

The co-ordinated subjects of control of explosives, rescue-work, resuscitation, and first-aid demand national interest. The Pittsburgh National Demonstration was a wonderful exhibition in itself. Its true object, however, was to appeal to the common-sense of employers and employees, and to acquaint the public with the work of the U. S. Bureau of Mines. In this it was successful.

When the Dominion Mines Branch Station at Ottawa is constructed we would suggest that a similar public exhibition be organized.

In our next issue there will appear a complete description of each event.

FABRE TOWNSHIP, QUEBEC.

The geology of a portion of Fabre Township, Pontiac County, Quebec, is reported upon by Mr. Robert Harvie, Jr., in a late bulletin issued by the Quebec Mines Branch. Before proceeding to notice the contents of the report, we wish to compliment the Quebec Department upon the greatly improved typography and general make up of the bulletin. The colour geological map is excellently done. It is quite on par with the productions of the Ontario Bureau Mines.

Fabre Township lies on the east side of Lake Temiskaming, just within the boundary of the Province Quebec. In physiographical characteristics the country resembles the adjacent parts of Ontario.

In general, the geological features comprise types of the glacial, the post-Huronian, the Huronian, the Laurentian, and the Keewatin. There is no need particularizing on this side. We shall notice, instead, the specific conclusions arrived at by Mr. Harvie. These are interesting for several reasons, but mo especially from the facts that much activity has been centered round the whole region and many rumours of rich discoveries have emanated therefrom.

Summing up the economic aspects of the field, Mr. Harvie points out first that the veins are narrow, the average width, with the exception of a few Keewatin copper veins, being under three inches. Second, except in a few cases, the veins are short and pinch out quickly. Third, most of the veins are made up of almost barren calcite and quartz. Third, it is a matter of great difficulty to transport supplies. Fifth, no workable bodies of ore have been discovered, nor has any valuable ore been found even in the small veins. Sixth, work undertaken by responsible persons has been abandoned.

This would seem to be a sweeping condemnation of Fabre Township. And in very fact it is. While it will be a bitter pill for many prospectors to swallow there appears to be no reason for seriously qualifying any of Mr. Harvie's statements.

A gleam of hope, however, irradiates the future. There are enormous bodies of workable clay in Fabre. Some day when other industries shall have been developed, this clay may be a source of wealth.

THE CLAYS AND SHALES OF NOVA SCOTIA.

Memoir No. 16-E, issued by the Geological Survey Branch, Department of Mines, Ottawa, embodies the results of an investigation of Nova Scotian clays and shales carried on by Dr. Heinrich Ries, assisted by Mr. Joseph Keele. Certain portions of New Brunswick were also included in the survey.

The important clay and shale deposits are limited to the lower Carboniferous, the Millstone Grit, the Coal Measures, the Permian, and the Pleistocene. While few in number, these bodies are of large extent.

Of all the above-mentioned horizons, the Coal Measures comprise the most important clay and shale formations. Examination of these measures failed, incidentally, to reveal the presence of considerable quantities of fire clay. Generally, large bodies of clay and shale in north-eastern Cape Breton will yield common brick, face brick, and, in some cases, low-grade fire-brick. From the Pictou shales and clays tile and brick of very fair quality are produced. In the Inverness field, on the west coast of Cape Breton, is found a particularly good clay that could be used for pressed brick, for fire brick, and for general stoneware manufacture. Its fusing point is about 3,000 deg. F. The body is from 18 inches to nearly three feet in thickness, and would have to be worked along with a 13-foot coal seam. It is highly plastic and possesses dense burning qualities. Common brick shale is found near the Port Hood colliery. Large exposures of tile and earthenware shale occur directly on tide water between Port Hood and Judique Harbour. No work has been done in this region.

The plastic, tough, red burning clays of the Pleistocene period are the basis of most of the present establishments. These industries are spread pretty well over the Province. Common brick is made largely for local demand, although from plants situated near tide water shipments are made to foreign countries.

Dr. Ries expresses the opinion that there is positive room for development. Between Ontario and Nova Scotia there are few pressed brick plants. Ontario produces more than 300,000,000 common brick, about 50,000,000 pressed brick, nearly 4,000,000 paving brick, and about 20,000,000 tiles. Quebec is credited with nearly 130,000,000 brick, and with a considerable quantity of tile.

Compared with these figures, Nova Scotia's output is small. The official returns for the year 1910 place the number of bricks manufactured at 21,305,500; and the number of feet of drain-tile at 974,819. It is probable that Montreal is the largest extra-Provincial consumer of Ontario's products. It is obvious, also, that Quebec is not producing on a scale sufficiently large to supply her own demands. Nor, for that matter, is New Brunswick.

Apart from the possibility of developing well-situated industries at strategic points on Nova Scotia's coastline, there are other fields to exploit. The Sydney and North Sydney iron and steel plants consume large quantities of fire brick. Fire brick made at Westville by the Intercolonial Coal Company is used satisfactorily in lining ladles. There are, however, presumably large deposits of fire clay near Shubenacadie and in the Musquodoboit Valley that, with the construction of the Musquodoboit Valley Railroad, will be given industrial value.

The opinion of an expert of Dr. Ries' standing commands attention. We have long been convinced that the clay industries of Nova Scotia would repay larger investment. The wide distribution of Dr. Ries' report should bring results.

* * * *

The report concludes with a highly instructive chapter on the origin and properites of clay, supplemented by a complete statement of the composition and fusing points of Seger cones, and by an exposition on the influence of the various chemical constituents.

It may be worth while mentioning that the photogravures are hardly up to the mark. This mars an otherwise excellent publication.

THE VALUE OF A BOOM.

The mining boom is an inherent part of the growth of the industry. Much as we may deplore its attendant evils, the boom appears to be necessary to the successful establishment of any mining camp. This applies more, of course, to the mining of the precious metals. Iron, coal, and the like, can be exploited without a rise of public temperature.

The Rossland boom, the Lake of the Woods fiasco, and, in later years, the Larder Lake and other excitements, illustrated very completely the disastrous consequences of inadequate publicity and the lack of clean professional talent. To these elements must be added the presence of unscrupulous vendors, visionary promoters, and a quite unsophisticated public.

Times and manners have changed. It is not easy to "do" the Canadian public to-day. Responsible publicists, having at heart their duty towards the nation, will not permit themselves to be used by the fakir. Every flotation must meet fair criticism. The subsidized press carries less and less weight.

Yet the fact remains that the normally constituted human being wishes to be in the fashion. If one camp or district happens to hold public interest, the investor is more easily persuaded to take a chance.

Nova Scotia gold mining started in the early 'sixties of last century. There was at the time a local effervescence, a disturbance that by no stretch of the imagination could be called a boom. Inordinate amounts of gold were won from small quantities of ore, particularly at Waverly, a small settlement near Halifax. As is nearly always the case, no provision was made for the future. The mining that was done was crude, mostly open-cast. The milling was, if one

may judge from the records, execrable. Yet many thousands of dollars were netted in clear profit. It will be easily understood that no stable industrial foundations were built.

The early methods obtaining in Nova Scotian gold mining tainted the whole history of the industry down to the present day. Individual initiative, in which inadequate capital has been a restrictive factor, and foolishly inflated corporate enterprises have marked the two extremes.

Mr. F. P. Ronnan's article, re-printed on another page, is timely. Mr. Ronnan accentuates the indubitable fact that gold mining in Nova Scotia must be taken on its own merits. Unquestionably a boom is needed. But, if good is to ensue, that boom must be carefully directed in the proper channels.

If any situation can be fairly gauged in a few words, it is not beyond the mark to affirm that dozens of Nova Scotian gold mines, if properly and fully reported upon, would show up better than prospects in other parts of the Dominion that have been floated for millions.

To those investors, engineers, and others who find no resting place for their feet in the camps that are now popular, we would suggest that they turn towards the unadvertised fields of Nova Scotia.

EDITORIAL NOTES.

India's coal output for 1910 was 12,000,000 tons, of which quantity less than 1,000,000 tons left the country. The domestic use of coal is trifling. Cow dung is used extensively as a fuel in agricultural districts.

Since the year 1900, Japan's annual mineral ou has increased in value by 60 per cent. The t nominal capital of mining companies is about $1 000,000.

The Elusive Bill Miner, for whom iron bars and st walls do not a prison make, has been re-captur Bill's subliminal self was seen on a T. & N. O. t on its way to Porcupine. It is still at large.

The Toronto Branch of the Canadian Mining I tute at a recent meeting passed unanimously a r lution felicitating the Dominion Government upon appointment of Mr. R. W. Leonard to the position Chairman of the Transcontinental Railway Comm sion.

Politics apart, it rouses the ire of every decent C adian when he reads of the public utterance of J. J. A. Maedonald. In the course of a speech in American city, the reverend editor of the Globe reported to have explained that reciprocity had b defeated by the United States interests. He calm assured his hearers that Canada's verdict had b purchased for $1,500,000. The devout doctor could buy even Larder Lake with that sum. Why not cept defeat in a sportsmanlike spirit? Even Ca adian mining men possess a certain love of count and pride of race. Canadians, as Canadians, shou demand an explanation of the immoral and extrav gantly silly assertions of a man who is supposed foreigners to represent advanced Canadian thought

CORRESPONDENCE

A SUGGESTION FROM THE WEST.

THE EDITOR:—

Sir,—I see nothing original in the proposal of Robert Hedley and others to saddle the Government with the correction of bad mining companies. Such propositions assume that the Government is a wise and benevolent parent, alert to guard its children from burning their fingers with incautious mining investments. As a matter of fact, governments are almost as sinfully human as mining companies, and experience shows us often enough how easy it is for governmental interference with private industry to degenerate into persecution or downright blackmail.

The licensing of surveyors and assayers under the laws of British Columbia certainly restricts competition and increases the cost of such service; whether it improves the quality of the service is doubtful. I believe it is the common opinion that without the protection of their government certificates some men of these professions would be seeking other fields of endeavour. As it works out, every provincial land surveyor whose business warrants, employs unlicensed men to do their work, pays them at competitive rates, and by virtue of the Land Surveyors' Act, gets a rake-off from the public for each employee's services. If a profession man can not stand on his own legs, why bolster hi up with a government certificate? There is a touc of humour in the recent amendment to the Land Su veyors' Act, whereby the canny B. C. Government permitted to employ its surveyors in the open mark while the common people are required to patroniz the P. L. S.

We are all agreed that mining promotions need reg lating, but why take our troubles to an already ove burdened Government when there is a simple and e feetive remedy right at hand? In the Canadian Mi ing Institute we have a company of public-spirite gentlemen who know what they are about in minin matters as no government ever can. Let them issu a monthly bulletin by authority of the Institute, sort of Investors' Guide, wherein discreditable pro motions are plainly pointed out, with concise reason why they are discreditable. Fear of libel suits woul keep the publishers close to facts and the inevitabl criticism would induce among the Institute's own mem bers a salutary caution with respect to participatio in dubious enterprises. If the gentlemen of the In stitute should undertake such a public service without

exacting a large fee, they would appear in an rely new and by no means unfavourable light. h an undertaking would vastly increase their im- ance in the eyes of the general public and might become profitable.

WILLIAM W. BUSH.

ewart, B.C., Oct. 17, 1911.

TORONTO BRANCH C. M. I.

Toronto, November 9, 1911.

tor CANADIAN MINING JOURNAL:

ir,—In connection with the two motions passed by Toronto Branch of the Canadian Mining Institute, ts meeting in Toronto on Saturday, October 28th, following will be of interest.

he first motion was in the form of a resolution of gratulation to the Dominion Cabinet on the ap- tment of R. W. Leonard, Esq., C.E., to the office of irman of the Transcontinental Railway Commis- n. This appointment is regarded by the Toronto nch as emphatically the best choice that could e been made. I have received a reply as below from Premier, the Hon. R. L. Borden, to whom I was ructed to forward a copy.

Prime Minister's Office, Canada.
Ottawa, Ont., Nov. 6, 1911.

My Dear Sir,—

Your letter of the 31st October reached me upon my return to Ottawa. Will you kindly convey to the Toronto Branch of the Canadian Mining Institute my thanks for their resolution relative to the appointment of Mr. R. W. Leonard as Chairman of the Transcontinental Railway Commission. I am glad to learn that this appointment is meeting with the general approval of the public of Canada.

Believe me,

Yours faithfully,
(Signed) R. L. BORDEN.

W. E. H. Carter, Esq.,
Secretary Canadian Mining Institute,
85 Front St. East, Toronto, Ont.

By the second motion a committee of five members s appointed to "investigate the subject of Work- gmen's Compensation, with particular reference to rkers in mines and allied industries," and to pre- re a memorandum of recommendations from this anch to be forwarded to Chief Justice Sir William eredith, for his consideration, at the time of his hear- g of the whole subject. The committee will consider e important attitude of compensation directly in pro- rtion to investment. Furthermore, I believe it was e feeling of the meeting that any expression of opin- n should be entirely impersonal on the part of the ronto Branch of the Canadian Mining Institute, d that the aim be to devise recommendations that ll be mutually acceptable and profitable to both par- s.

Sir Wm. Meredith was notified of the action of this anch, and has replied to me as follows:

The High Court of Justice for Ontario.
Osgoode Hall, Toronto.
November 4th, 1911.

Dear Sir:—

I have yours of the 3rd inst.

I shall be glad to have the benefit of the report of your Association and shall keep the Commission open as long as possible to enable you to prepare it.

Yours truly,
(Signed) W. R. MEREDITH.

The Secretary,
Toronto Branch Canadian Mining Institute,
85 Front Street East.

Yours sincerely.
W. E. H. CARTER, Secretary.

Personal and General

Mr. G. H. Gillespie, managing director of G. H. Gillespie & Company, talc producers, Madoc, Ont., was in Toronto on Nov. 6th.

Mr. J. J. Harpell, formerly business manager of the CANADIAN MINING JOURNAL, visited Toronto Nov. 1st.

Mr. R. H. Stewart, managing director of the Consolidated Mining & Smelting Company, left Ottawa early in November for Trail, B.C.

Dr. Milton Hersey, who recently suffered serious injury to his eyes, is recovering rapidly.

Mr. T. H. Rae will make Toronto his headquarters during the winter.

Mr. H. P. Davis was in Toronto recently on his way to Cobalt, Swastika, and Porcupine.

Messrs. E. T. Corkill and J. C. Murray attended the National Safety Demonstration at Pittsburg on Oct. 30th and 31st. Other Canadians present were: the Hon. Mr. Tolmie, Deputy Minister of Mines for British Columbia; Inspector Strachan, British Columbia; Mr. J. Hudson, Mines Branch, Ottawa; and Mr. McMahon, Dominion Coal Co., Sydney.

Dr. A. E. Barlow attended the last meeting of the Toronto Branch of the Canadian Mining Institute.

Mr. W. F. Ferrier is the new chairman of the Toronto Branch of the Canadian Mining Institute, and Mr. W. E. H. Carter the secretary.

Mr. T. W. Gibson, Deputy Minister of Mines, Toronto, was present at the American Mining Congress, Chicago.

Mr. P. L. Nasmith, of Lethbridge, Alberta, general manager of the Alberta Railway and Irrigation Company, owning the Galt collieries, situated near Lethbridge, was recently in the Crow's Nest district of British Columbia.

Mr. Douglas Lay, superintendent of the Van-Roi Mining Company's silver-lead-zinc mine and concentrating mill in Four-mile camp, near Silverton, Slocan Lake, spent a holiday vacation at Spokane, Washington, last month.

Mr. James Ashworth, of Vancouver, B.C., has been engaged by the Head Syndicate, Limited, to examine and report on a coal mining property, situated on the south fork of Old Man River, in southwest Alberta, owned and being developed by the syndicate, with Mr. Leslie Hill, of Nelson, B.C., as engineer and manager.

Mr. Robert Irving, of Vancouver, B.C., secretary of the Slocan Star Mines, Limited, recently organized by Mr. R. S. Lennie, also of Vancouver, to acquire and operate the Slocan Star and Rabbit Paw groups of mineral claims, has returned to Vancouver from a visit to the property, which is in the vicinity of Sandon, Slocan.

Mr. W. C. Bayly, of Nelson, B.C., secretary of the Nugget Gold Mines, Ltd., of Sheep Creek, has left British Columbia on a trip to Europe and other countries, and will be away several months.

Mr. M. K Rodgers, well known in British Columbia in connection with the earlier development of the Nickel Plate and Hidden Creek mines, is now associated with Mr. T. D. Pickard in prospecting the Apex group, in Hedley camp, Similkameen, which property has been secured by them under option of purchase.

Mr. I. L. Merrill, president of the Hedley Gold Mining Company, is on one of his periodical visits to the company's Nickel Plate group of mines and stamp mill in the Similkameen district of British Columbia.

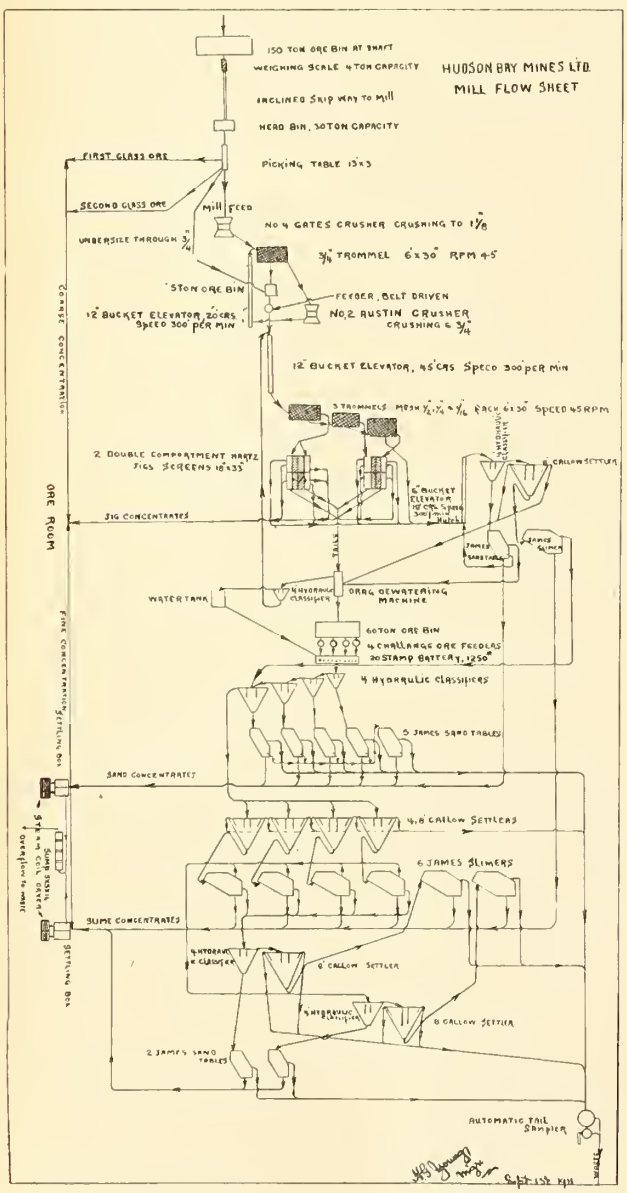
Mr. Thomas Kiddie, of Vancouver, B.C., is arranging to take a trip to Morenci, Arizona, where his e[lder] son holds an important position with one of the la[rger] companies operating in that state.

Mr. O. E. LeRoy, who has been supervising the f[ield] work of several Geological Survey parties in the K[oot]enay and Boundary districts of British Columbia, is about to return to Ottawa, the season's outdoor w[ork] having been completed. Mr. W. H. Boyd, who [has] been doing topographical work in the Blairmore-Fr[ank] district, Alberta, left for Ottawa about the middle [of] October.

Mr. Arthur Fisher announces his resignation [as] manager of the North Western Asbestos Mills C[om]pany, the Wyoming concern which has advertised [its] stock throughout Canada.

Concentration at Hudson Bay Mines, Ltd., Cobalt, Ont.

Written for the CANADIAN MINING JOURNAL by H. G. Young.



Nature of the Ore.

The silver values occur mostly in the vein as[so]ciated with niccolite, smaltite, and calcite. The co[un]try rock near the vein, sometimes for 12 inches [on] each side of it, carries leaf silver. These veins oc[cur] in the conglomerate formation.

Flow Sheet.

In our shaft house there are two landing decks, [one] fifteen feet above the other, and between the t[wo] there is installed a storage bin for mill ore, of [one] hundred and fifty tons capacity. All ore is hand[led] at the second deck and dumped from the cars into t[his] bin, with the exception of the first-class ore, which [is] dumped on the floor and high grade picked out, t[he] balance going to the storage bin. At the bottom a[nd] along the front of this bin there are arranged fo[ur] gates from which the ore is drawn off into a sk[ip] which passes under them. Underneath the track th[ere] is installed a four-ton weighing scale, so adjusted th[at] the weight reading is zero with the empty skip [on] The weight recorded for each skip is thus net ore. [By] pressing a lever the scale records the weight on a ca[rd] These cards are delivered at the office at the end [of] each shift, and the tonnage reckoned. The skip [is] then drawn up an incline to the mill by a small fr[ic]tion hoist which is belted to a line shaft in the mi[ll] where it dumps automatically into an ore bin and r[uns] turns. The ore is fed from here onto a picking tab[le] three feet wide and thirteen feet long, which is hu[ng] from supports by four eight-foot rods, and has a slo[pe] of one foot. The table is given a reciprocating m[o]tion by a Park's pusher, which is operated by a[n] At the end of the back stroke it bumps against su[p]ports which cause the ore to travel forward. In th[e] ore bin gate there is placed a roller three feet lo[ng] by twelve inches diameter, with a two-inch shaft [in] the centre. Attached to this shaft on one side the[re] is a ratchet wheel and a pawl with spring and ar[m] two feet long fits into the ratchet. The arm is a[t]tached to the table. As the table reciprocates the ar[m] travels forward and back, and causes the roller to tur[n] and feed ore evenly onto the picking table. Any firs[t] or second-class ore is picked out on this table an[d]

own into a bin. The balance drops off the end into umber four Gates crusher set to one and one-eighth hes, which is directly beneath. This ore is our mill d. We find this picking table a very good arrangeat for both hand sorting and for crusher feeding, as feed is steady and well distributed and there is no dling of the ore necessary. The first and second-ss ore is cobbed, sampled, bagged, weighed, and ged for each shift. From the number four crushhe ore passes to a revolving screen of three-quarter h mesh. The oversize goes to a number two Austi crusher, set to three-quarter inch, and the prodt returns to the screen. Thus, all mill feed passes ee-quarter inch and drops into a small bin. The ore elivered from this bin in a steady stream by a 12-h bucket elevator, which raises it to the sizing eens over the jigs. These screens give us four prots, over one-half inch, over one-quarter inch, over -sixteenth inch, and under one-sixteenth inch mesh. first three are delivered to four Hartz jigs, double partment type, with 18 by 33-inch screen, over one-f inch being split in two equal parts. The concenes are skimmed off and thrown in a box two feet 4 feet by 6 inches. This box has a pipe leading into bottom of it, which conveys the ore to a small hopin the ore room. Before sending to the ore room the ive silver is picked out and dropped in a small ked box through a hole in the top. The jig tails to the dewatering machine. The hutch joins the ersize from the one-sixteenth inch mesh trommel is raised to a four-foot hydraulic classifier, where sands are removed and go to a number two James e. The concentrates from this table go direct by ipe to the sand concentrate collecting tank in the room. A corner middling is returned and tails go he dewatering machine. The overflow from the raulic classifier passes into an eight-foot callow er and the slimes are treated on a James Simplex er. The concentrates go direct to a slime concene settling tank in the ore room. The tails go to sifier in front of the stamps. The dewatering ma-e simply drags the ore out of the water and ders it to a belt distributor of reversible type, over stamp bin. The water passes through a small er and into the storage tank behind the battery is re-used.

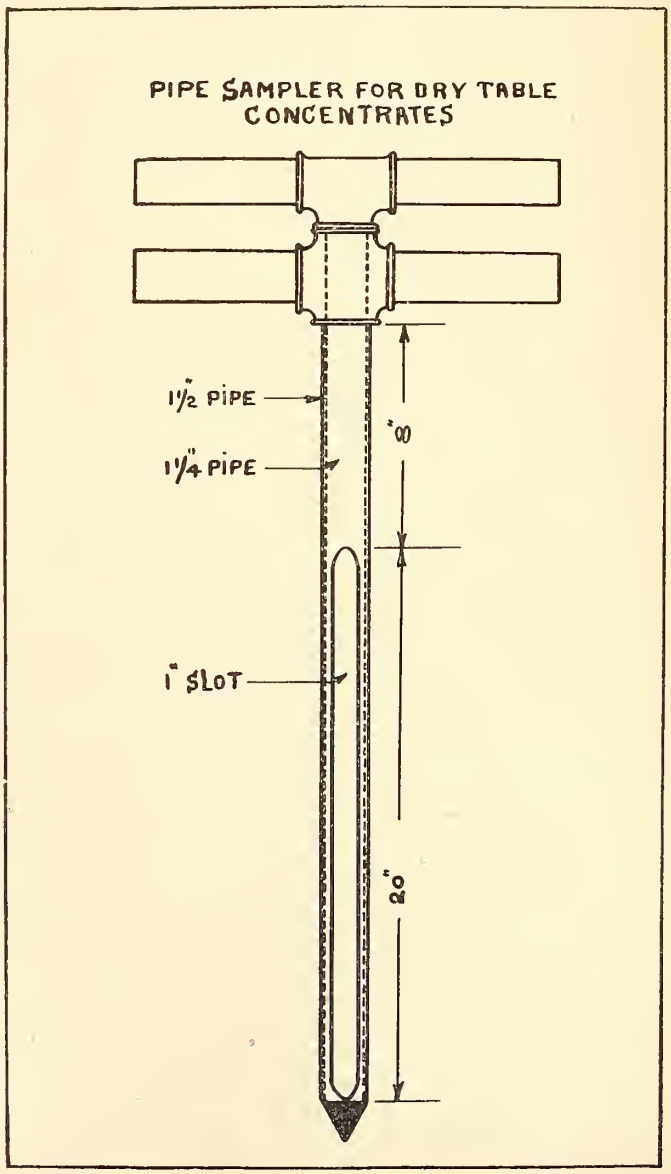
ur battery consists of 20 Fraser & Chalmers 1,250 nd stamps. The morters are the narrow type with discharge, and weigh 9,000 pounds each. They arranged with water service behind each die. We 16-mesh roll slot screen, manufactured by B. ening Wire Co. Rate of drop is 100 per minf; distance, six inches. From the stamps the pulp ses into a chain of hydraulic elassifiers. The sands delivered to four number two James sand tables. centrates from these tables go direct to a tank in ore room, and the tails to the waste launder. A ner middling is taken from each table and treated a number two table. The tails go to the waste der. The slimes are carried over and distributed four eight-foot callow settlers, the overflow going he waste launder and thickened slimes onto four plex James slimers. The concentrates are carried pipe to the ore room. The corner middling is ed and passes through a four-foot hydraulic classi-The coarse product is fed on a number two James table and the overflow passes into an eight-foot w tank. The concentrates go direct to slime coling tank and the tails to waste launder. The tails from the four slimers go through the same process as the corner middlings.

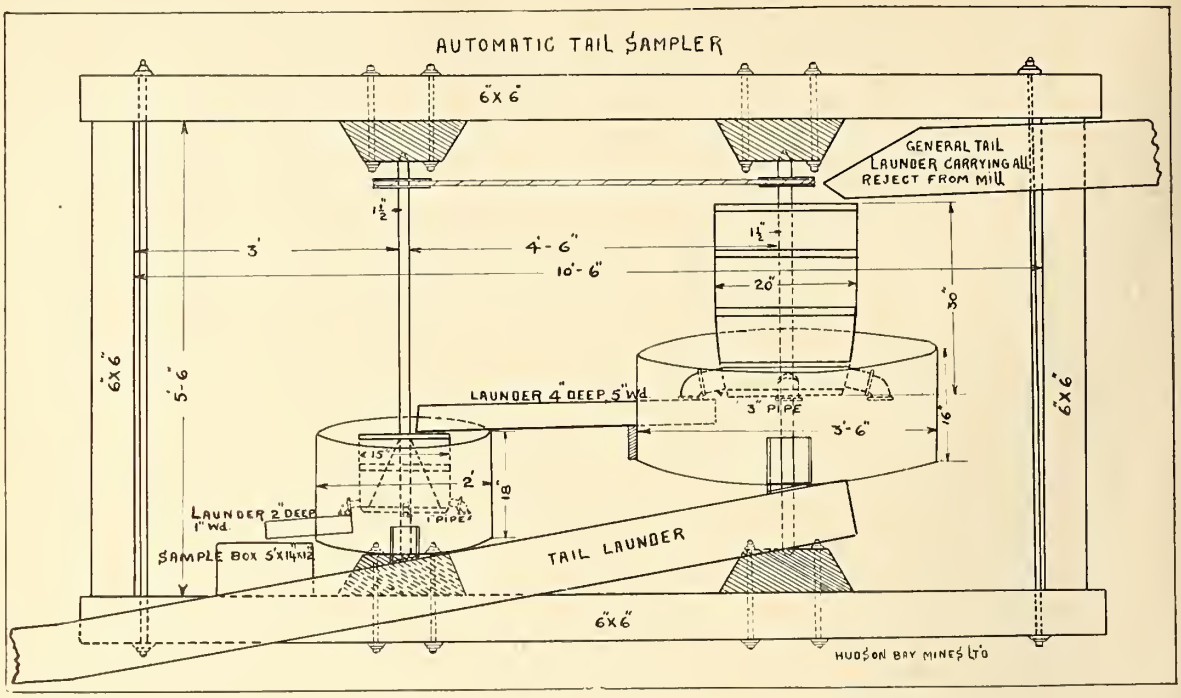
The concentrate collecting tanks in the ore room are two feet by three feet by eight feet, and there are two for sands and two for slimes. Each morning at seven o'clock the delivery pipes are switched over to an empty tank and the concentrates for the previous 24 hours are dried on a steam drier, 16 feet by 6 feet, made of one inch return pipe. The pipe rests on a quarter-inch mesh screen. As the concentrates dry, they drop through the screen into a hopper, from which they are drawn off by a gate, and bagged. They are sampled, weighed, and tagged and put away. In this way we get our concentrates almost perfectly dry, the moisture in eleven cars averaging as low as 0.6 per cent. The overflow water from the collecting tanks passes through a settling tank five feet by five feet by eighteen feet, arranged with three baffle boards. The overflow water from this goes to waste. This tank will catch on an average two hundred dollars per month, and we find it a splendid arrangement to prevent losses of ore already won.

Sampling.

(1) Dry Table Concentrates.

The above cut shows the sampler used for this purpose. It consists of a one and a quarter inch pipe in-





side of a one and a half inch pipe. A twenty-inch slot one inch wide is cut in each pipe. A bag is put over a bag filler and the sampler plaeed inside. The gate is opened and the bag filled. The inside pipe is then turned through 45 degrees and the sampler removed from the bag and held over the sample box, where the inch and one-quarter pipe is pulled out, giving you a sample for that bag. This is done with each bag filled, and the sample which represents the ore for 24 hours is sent to the assay office. You will note that this sampler gives a cut from the bottom to the top of the bag, and has given us remarkable results in accuracy.

(2) Jig Ore.

You will remember that this is delivered by a pipe to a hopper in the ore room. This hopper is about 3 feet off the floor and has a small gate in the bottom, which will, when open, let the ore discharge in a small compact stream. A bag bag filler inserted is placed under the gate and gate opened. When the ore is passing we take cuts out of the whole stream in filling one bag, this is continued till the ore is all bagged and sample sent to the assay office.

The following table will demonstrate the results tained by the above method of sampling table and concentrates:

Car No.	Mill Assay.	Smelter Assa
1	713.7 ozs.	721.3 ozs.
2	258.7 ozs.	262.5 ozs.
3	360.0 ozs.	360.4 ozs.
4	497.0 ozs.	499.0 ozs.
5	1,228.4 ozs.	1,230.9 ozs.
6	527.0 ozs.	525.8 ozs.
7	527.0 ozs.	526.0 ozs

Summary

Total Ore Treated by Stamps	2041.1 Tons.
Average Capacity per Stamp per 24 Hours	4.08 "
Average Capacity per Stamp per 24 Working Hours	4.15 "
Average Assay to Mill	44.6 ozs.
Average Percentage of Extraction	88.7
Weight of Metallics 194.5 Lbs. Value in Ounces	1945.0 ozs.
Total Production for Month in Ounces	2058.30.3 ozs.

Cost of Milling per Ton #1.034

Expenses

	#
Repairs & Maintenance	330.20
Power, Heating & Lighting	640.00
Supplies	28.96
Salaries & Wages	1112.27
Plant	1296.33
Total	3407.76

H. S. Young Manager

(3) **Hard Ore.**

The first and second-class ore is cobbed by an experienced hand and the sample taken as he is doing the work.

In our mill we make five classes of ore, namely:—first-class ore, second-class ore, jig concentrates. sand concentrates, and slime concentrates. For each class of ore we use a tag of certain colour, and when each bag is sewed up and put away it is tagged. On this tag we mark the date, number of the bag, and weight. When we desire to ship a car of ore we are thus able to pick out any day's ore in the mill, and we know its assay value. Thus we can grade our shipments in order to take advantage of smelters' tariffs. Also, if when we get our assay returns, we have any reason to believe that the sampling of any class might be in error, we can always pick out that day's ore again and resample.

(4) **Tail Sample.**

All reject from the mill, consisting of sands, slimes, overflow from the callows, and wash water from the floors, passes out the general tail launder and through the automatic sampler shown in the cut. The impact of this stream causes the 20-inch barrel to revolve and the tailings discharge through four 3-inch pipes in the side at the bottom. The 4-inch launder catches the whole stream from each pipe as it passes over it and delivers into the small barrel shown. The smaller barrel revolves by belt connection to the larger one. The pulp passes out through one-inch pipes and the sample is caught in a two-inch launder, which delivers it to the sample box. This box is cleaned out every 24 hours and sample assayed.

The following screen analysis of tails will be interesting:

October 24th, 1911.

Mesh.	Per cent.	Assay.
	oz.	oz.
On 16	2.51	5.5
On 40	15.66	1.2
On 60	18.66	0.8
On 100	4.29	0.5
On 150	10.54	1.5
On 200	5.11	1.6
Through 200	43.23	6.0
	100.00%	

Average assay, 3.32 ozs.

October 25th, 1911.

Mesh.	Per cent.	Assay.
	oz.	oz.
On 16	2.63	2.3
On 40	16.68	1.0
On 60	19.71	0.8
On 100	4.40	1.6
On 150	9.53	1.6
On 200	8.74	1.6
Through 200	38.41	6.1
	100.00%	

Average assay, 3.06 ozs.

The following table will illustrate our experience with hand sampling as compared with automatic sampling of tails. In hand sampling the tails we were very careful, using a wash tub of about twenty gallons capacity and taking a cut of the whole stream of sands and slimes every fifteen minutes, and allowing it to settle carefully before decanting.

Hand sampling.

	Assay heads.	Assay tails.
April 27th	26.1	6.5
April 28th	29.5	5.5
April 29th	26.8	6.4
May 1st	20.4	5.4

Automatic sampling.

	Assay heads.	Assay tails.
May 2nd	22.1	9.9
May 3rd	20.4	8.2
May 4th	19.1	9.3
May 5th	20.3	7.0

The automatic sampler was put in service on May the 2nd, and if you work out the percentage of extraction from heads and tails you will find that immediately, as the automatic sampler came in service, we discovered that the losses in our tails were easily 10 per cent. greater than we had anticipated.

Monthly Mill Sheet.

Our mill feed is figured on the product crushed from the picking table. All ore going to the mill is weighed. Thus in our data on this sheet the weight of second-class ore recovered must be deducted from the ore hoisted in order to give us the weight of mill heads. In the line marked "Totals," for assay values these figures represent average values for the month. All first class ore was picked out at the shaft and is shown here because we keep all ore data on one sheet for convenience. All other data should be perfectly clear.

The horse power required for the mill is 130, in which is included a 30 horse power pump at the lake, supplying the mill and plant. Our jig floor only operates one shift, of 11 hours, and we find this arrangement economical in labour and power.

For each 24 hours we have an accurate and reliable sample of our loss in tails. We also have an accurate sample of dry concentrates recovered, together with the weight. We know also exactly the weight of ore put in to the mill. With this fundamental data accurate, we have every reason to believe that all data contained in our monthly mill sheet is absolutely reliable. There are days, as you will note, on which we have done excellent work. However, I wish to print only what is our average, and thus I have put in a whole month's work, which covers high and low marks.

In this paper I wish to heartily commend the work of Mr. E. Brewer, my mill foreman, who has looked after our work in a very capable manner.

A Neglected Field

By F. P. Ronnan.*

It has been estimated that the combined area of our several gold districts will equal about 5,000 square miles. To attempt to enumerate the actual number of gold bearing veins already opened would mean to use up the entire space of this issue of the Advocate, giving a line only to each gold bearing vein. It has been humorously remarked that every man in Nova Scotia owns a gold mine, and the statement, while

*Editor the Industrial Advocate, Halifax, N.S.

exaggerated, is not so far from the truth as one might think at first reading.

The average Nova Scotian believes in the gold mining future of his province — that is, in the abstract, but it is difficult work to get him down to the concrete principle of putting his capital in such ventures on a hard practical business basis, and yet, he has squandered a great deal of money in the past 43 years in mere surface work which has served only to prove the wide extent of mineralization without returning him a reward sufficient to pay him for his trouble. Now if there be one avenue of development more important than another, in which the future of this province is wrapped up it is the problem of how the full advantage may be taken of these magnificent mineral deposits. Many geological authorities have traversed its fields and have arrived at the conclusion that there are available profitable openings for exploitation. Mining engineers from various portions of the United States have arrived at practically the same conclusion. Naturally the question will propose itself, under such circumstances, why is it that an industry of such possibilities is in a backward condition? And the only answer that can be made to such a reasonable question is that Nova Scotia in her entire mining history is the one known gold mining camp in the world which has not yet enjoyed the benefits of a boom.

The word boom is used because, perhaps, it best describes the condition which appears to control the birth of world-famous camps. We all know that the so-called boom, more familiar perhaps to the west than the east, is not an unmixed blessing, yet without it the investing classes would never have been induced to furnish the capital for developing famous producers. It is not intended to advocate for Nova Scotia a boom, because there has scarcely been one movement of this character in connection with mining districts that has not resulted in a great deal of loss for many persons, yet with the redeeming feature that it has brought about the addition of many important producers of precious metal to the world's supply.

In no other part of Canada is gold found of such free milling character. In no other locality are labour conditions so favourable. Almost every known gold-bearing district is within 20 miles of the Atlantic, and the larger portions of them are directly on the coast line, thus rendering transportation of supplies a comparatively simple and inexpensive item. The size of the lodes will vary from the thickness of a jackknife blade to belts of ore bearing material as wide as 50 feet. It would be impossible to go into the structural geology of the gold occurrences of this province, nor would the average reader appreciate the conclusions and data of these learned men who have studied the methods of deposition and the genesis of our ore bodies. The average investor wants to know where he can put his capital safely and with fair expectation of obtaining as great a reward as possible. And it would seem from a close study of the various districts of this province that there exists here numberless opportunities where these conditions may be obtained, if the same qualities which safeguard ordinary business undertakings are applied and sufficient capital be at the disposal of the operator. It has been a standing wonder to many why the same plan followed by English exploration companies should not find in Nova Scotia a favourable field for its application. So far in Nova Scotia the obstacle of labour unions, in so far as gold mining is concerned, is an unknown factor, and this is no small feature to be considered in the successful opening of our deposits. There are many water powers available in various districts which would still further assist in large scale mining operations.

Twenty-five years ago the five stamp mill was the rule. Five years ago the 10-stamp mill was the prevailing size of reduction plants. Now the 40-stamp mill is generally considered to be the proper means of treating the deposits in an economical manner. It can be readily understood, therefore, that mining and milling practice in this country has not reached perfection, and on that account the forecast of what the future may have in store for this province in the way of increased developments is very greatly strengthened.

In the past, operators have confined their attention to rich streaks of pay ore, and nothing under an ounce to a ton was worth considering, and rightly too, if looked at from the standpoint of the individual miner who wants only to extract these values which are most profitable, because of the smaller expenditure for labour, etc. This is the direction in which whatever development done in the past has been extended, and, therefore, the persons who have studied mining facts in connection with Nova Scotia have more faith in the future outcome of the development of large bodies of ore which will be worked upon a large scale, and at a minimum of expense, and it is from this class of deposits that the future of the industry will be determined, leaving the richer but smaller ore bodies to be worked in conjunction, and thus add to the general tenor of the mill output.

Milling practice in this province has in a few instances been reduced to the highly creditable point of 20 cents per ton of tails, a result which is surpassed by only a few properties in the world. It is fair to ask that if a totally unorganized body of miners, shifting from one district to another as a matter of convenience or whim, following no constant objective point, hampered by the lack of capital and facing the obstacles which nature puts in the path of those who would wrest her wealth from her, can produce nearly $17,000,000 worth of gold, what should follow the operations of say a dozen groups of thoroughly organized capitalists with the necessary technical skill directing their enterprises in such a country as Nova Scotia.

Perhaps the most important point that has been raised in recent years in connection with these gold deposits, is the probability of their richness with depth. By depth is understood, say, 3,000 feet. The deepest working in Nova Scotia at present does not exceed 1,000 feet vertical, and this occurs in but two districts. The average depth of shafts in Nova Scotia does not, perhaps, exceed 100 feet, though there are many which will run 300 to 500 feet, and it does not require extensive technical education to recognize the fact that a 250-foot shaft is little better than a prospect hole. It has been estimated that the thickness of our gold-bearing strata is in the neighbourhood of 7,500 feet, and the data available at present would seem to point to the maintenance of value to at least three times the present greatest depth. On this subject a considerable amount of literature has been issued, and the question has been a fruitful one for discussion among mining men. Mr. Faribault, of the Dominion Geological Survey, who has been studying the gold measures of the province for the past 30 years, gives it as his opinion that gold will be found at that depth, and he bases his

conclusions upon certain similarities between the formations of Bendigo and those of Nova Scotia.

The Government of Nova Scotia, to encourage those who would undertake the task, has placed upon its statute books, measures which commit it to furnish one-half of the cost of underground work, including shaft sinking and crosscutting, an advantage that is offered in no other country to our knowledge, in the world. Up to the time of writing such a measure of assistance has not been taken advantage of, although several mining companies have made incomplete applications therefor.

A word or two in reference to the conditions under which mining may be carried on. With particular reference to government requirements, it may be said the tax of 2 per cent. on the gold produced, of which it is possible to obtain a refund by way of rentals, is a comparatively moderate one. Mining claims in Nova Scotia measure 150 x 200 feet. The shorter measurements being in the direction of the veins. Fissure veins occur in a number of districts and are considered as being of more promise than the usual bedded vein. Almost every district has been mapped by the Dominion geological authorities, and it is possible to obtain a great deal of detailed information regarding the size of veins, the depth of various shafts sunk in the past, and such information as would be of value to a serious investigator.

Had it pleased Providence to create Nova Scotia in the midst of an arid desert surrounded by nearly impassable mountains, peopling it with ferocious races, together with many drawbacks of climate, etc., the chances are that the adventurers of all nations could not be kept from exploring her riches by a cordon of gatling guns. This recalls the old story of the difficulty a man would have of selling newly minted gold dollars for fifty cents to the casual passers-by, who will not take time to determine whether they are genuine or not.

MEETING OF AMERICAN MINING CONGRESS

Written for the Canadian Mining Journal by T. W. Gibson.*

The 14th annual session of the American Mining Congress was held in Chicago from 24th to 28th October, President John B. Dern, the veteran gold mine operator, of Salt Lake City, in the chair. During its earlier years the Congress was not taken very seriously, but it has since developed into an important and influential body. The Chicago meeting was addressed by Dr. J. A. Holmes, Director of the Bureau of Mines, Washington, D.C.; George Otis Smith, Director of the Geological Survey, Washington; also by Hon. W. L. Fisher, Secretary of the Interior, and by President Taft himself. The body of the Congress was made up of representatives of the gold, silver, and copper interests of the western states; coal operators from Pennsylvania, West Virginia, Illinois, Ohio, etc., and a very considerable sprinkling of federal and state officials, such as geologists, mining inspectors, and others.

A number of the subjects discussed pertained to conditions peculiar to the United States, such as the Alaskan situation; the Sherman Anti-Trust law, etc., while others were of more general application. Representatives from Alaska were most vigorous in their denunciation of the United States Government's policy in dealing with the coal lands of that territory. The situation at present there is, that while there are large and valuable beds of coal in Alaska, the Government has withdrawn them from disposal, and all the coal locally used must be imported from British Columbia at a cost of $16 or $17 per ton. Secretary Fisher took the opportunity of announcing that the Government had decided upon a policy of leasing the coal lands instead of selling them outright, and intimated that railway facilities would be encouraged. It appears quite probable that the present importance of the Alaskan coal deposits has been over-rated. There are two known fields of good quality, the Behring River field and the Matanuska field, but in the former, which is the most accessible, there have been disturbances which have injured the physical condition of the coal and increased the difficulties of winning it. The Pacific coast as a market for fuel has also been largely preempted by petroleum, of which the Californian wells continue to yield enormous quantities. It is, therefore, doubtful, whether if the Alaskan coal mines were opened to-morrow the product would find an extensive sale.

Meeting in the east, the coal-mining industry received a large share of attention. Complaints from coal mine operators were loud and doleful. Competition is exceedingly keen, and profits are low, or even non-existent. West Virginia has some easily worked seams of good quality, and the price at which the product is marketed leaves little margin for mines where the coal is poorer, or more expensive to get out. All the coal operators united in denouncing the Anti-Trust law, declaring that it must be modified to allow of reasonable combinations, otherwise the trade would end in bankruptcy.

A subject that is of present interest on both sides of the line was discussed, in the shape of a proposed measure of compensation for accidents to workmen. Uniformity of law is desirable on the point, but the matter being under the jurisdiction of the individual states, it was recognized that this would be difficult to obtain. A committee appointed at a previous session of the Congress submitted a draft measure, which was approved. It provided:

(1) Compensation on a fixed scale for all accidents, regardless of their cause, "contributory negligence," etc., being practically eliminated. The maximum compensation for death was placed at $3,000.

(2) Compensation to be paid out of a fund raised by a tax of one cent per ton on all coal mined. Employees were not called upon for any contribution.

(3) The fund to be administered by a state-appointed advisory board of three members, one member to be a coal operator, and one a coal miner.

(4) Acceptance of compensation from the fund to be a bar against any suit against the employer for damages.

*Deputy Minister of Mines for Ontario.

As will be seen, the measure applied to the coal mining branch of the industry only, and did not attempt to cover the field of metalliferous mining. Some of the speakers thought the miners themselves should contribute to the fund, say on a basis of one per cent. of the monthly pay-roll. It was thought that a fixed rate per ton contributed by all mines, would give no advantage to well-equipped properties where every precaution against accident was taken, over those mines where recklessness prevailed, or which were insufficiently equipped, while if the miners paid into the fund they would have a strong incentive to guard it against depletion by fraudulent claims.

More generous appropriations to the Bureau of Mines were advocated. The opinion prevailed that while the Bureau was serving a useful purpose, its field had so far been limited largely to the problems presented by the coal mines of the east, the metal miners of the west being neglected.

Accidents, economies of the coal trade, conservation methods as applied to mining, and other subjects of interest were discussed. Not the least instructive was a paper by the veteran Canadian, Dr. James Douglas, of New York who described the Copper Queen Company's collieries and coke plants at Dawson, New Mexico, involving an investment of two millions of dollars.

The Canadian delegation this year was small, consisting of Mr. H. H. Lang, of Cobalt, and Mr. T. W. Gibson, Deputy Minister of Mines.

The Use of the Pulmotor in Metal Mining

Written for the Canadian Mining Journal by E. T. Corkill.*

Since the organization of first aid to the injured societies in Germany about thirty years ago, great progress has been made in the development of oxygen resuscitating apparatus for rescuing the lives of workmen who have been overcome with poisonous gases in the mines. Apparatus of this nature is now being largely used in the great coal-producing countries of the world. Rescue stations have been or are now being established at suitable centres of every large coal field. These stations are equipped with oxygen helmets, pulmotors, bandages, splints, antiseptic dressings, and various first aid appliances, and are placed in charge of a corps of men trained in the use of this apparatus and first aid appliances. The oxygen helmet has been used with great success in rescuing men after explosions and fires in coal mines, and has been used to a lesser degree in the extinguishing of fires in metal mines and in saving men entrapped by fire. After these explosions and fires, many of the injured, when brought to the surface, are unconscious as a result of inhaling the poisonous gases. As a means of resuscitating these men the pulmotor was invented. The apparatus consists of a cylinder in which oxygen is stored under a pressure up to 125 atmospheres, a blowing and suction valve actuated by two accordion bellows; a face mask which encloses the mouth and nose, making an air-tight connection with the face, to which a mask is attached, two flexible tubes leading to the blowing and suction valves respectively.

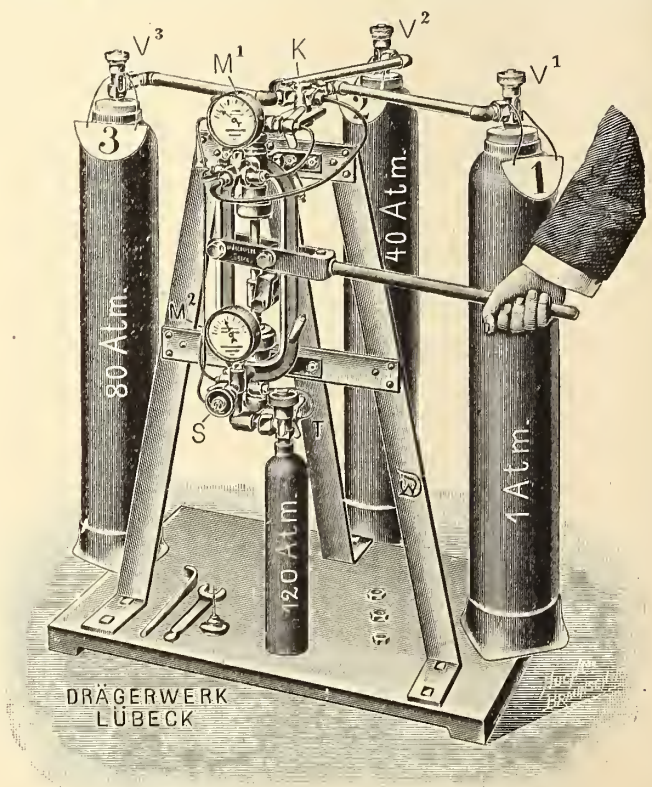
*Inspector of Mines for Ontario.

When the mask is made air-tight on the face and the oxygen turned on, the apparatus works automatically. Oxygen is forced into the lungs until a pressure of 4 inches of water gauge is reached, which pressure is in connection with one of the accordion bellows, and owing to the elongation of the bellows under this pressure, the valves are turned and the pressure in the lungs released. The suction valve immediately begins operation and continues to exhaust the oxygen from the lungs until a vacuum of 4 inches of water gauge is reached. The oxygen used for creating this partial vacuum elongates the second accordion bellows and changes the position of the valves, allowing the oxygen again to be forced into the lungs, etc. A lever enables the inflow and outflow of oxygen to be regulated by hand, independent of the automatic device.

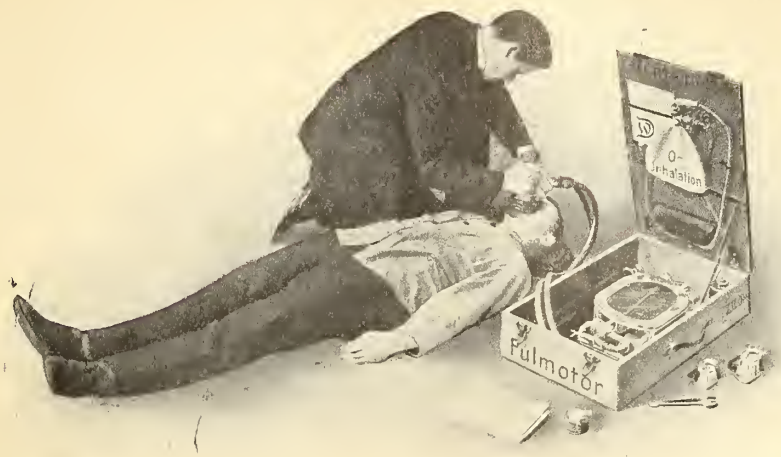
The application of this device necessitates placing the subject on his back, in which position the tongue may fall to the back part of the throat, allowing the soft palate to close the larynx. To overcome this condition, a flexible rubber tube is attached to the upper part of the face mask which will admit of grasping the tongue with a pair of forceps and withdrawing it sufficiently to raise the palate.

Another type of mask is one which fits over the nose and nostrils only, allowing the mouth to be free. With the use of this nose mask the tongue may be withdrawn and held between the teeth and lips with sufficient pressure to hold it in place and make the mouth air-tight. For the successful use of the apparatus it is necessary that an air-tight fit be made with the type of mask used.

Attached to the lid of the pulmotor is an inhalation device which may be substituted for the pulmotor as soon as the subject under treatment recovers the involuntary action of the lungs. This inhalation device is fitted with a rubber bag which holds two liters of oxygen when inflated, and a metallic mask which



The Oxygen Cylinders and Pump.



The Pulmotor in Service.

over the mouth and nose and which may be held place with a rubber band passing around the head. The apparatus has been used most successfully in resuscitation of persons who have been overcome through breathing irrespirable gases, by drowning or electric shock.

In metal mines many men are every year rendered temporarily unconscious through the inhalation of the gases which result from the explosion of dynamite, etc. In a number of cases they are not rescued in time to save their lives by the ordinary methods employed. In Ontario, during the years 1901 to 1910, 13 men lost their lives from this cause. A number of these men were not rescued until all signs of life were extinct, but there were a few who were still alive when brought to the surface but subsequently succumbed as a result of the poisonous gases inhaled. In addition to the fatalities there were a number of men who were rendered temporarily unconscious from inhaling gases resulting from dynamite explosions. These men were revived by the ordinary means of artificial respiration. If the pulmotor had been available, these men would not only have been revived sooner, but the gas would not have had as lasting effects. The best safeguard is to have the workings so well ventilated that poisonous gases cannot collect. Failing this, the next safeguard is to use artificial ventilation, such as fans, etc. If accidents then result, it is certainly advisable to have a pulmotor available for the speedy resuscitation of those workmen overcome by the irrespirable gases. The apparatus is automatic in action and any person can be trained in a very short time to its use.

The pulmotor has also proved very beneficial in resuscitating workmen who have received electrical shocks. The treatment is similar to that for poisonous gases, and if there is any heart action at all in the injured person resuscitation is very probable. Electricity is now in general use in the majority of metal mines, and accidents are therefore liable to happen from accidental contact with the wires no matter how carefully the wires, switches, etc., are insulated and guarded. It is, therefore, the duty of the operators to provide the best remedies obtainable for aid to the injured.

Stock Value and Mine Value

Written for the CANADIAN MINING JOURNAL by Dr. A. C. LANE.*

Continued from our Last Issue

I assume, then, that an unlisted copper mine figuring simply on its yield will, and should fairly, sell between well-posted business men at a price that would represent the payments to be received from it discounted at 7 per cent. compound interest.

Average Return from Listed Copper Mines 6 Per Cent. to 7 Per Cent.

I next take up the effect of increasing the marketability of copper mines in the raising of their price measured by the reduction in the yield. Taking the mean price of leading Lake Superior mines and comparing them with the return in dividends we find the average annual return in dividends on the mean annual price of the Lake Superior copper mines for 14 years between 1891 and 1910 to be almost exactly 7 per cent., varying in different years from 5.3 per cent. to 11.4 per cent. The figures for value given by Stevens are the average of the highest and the lowest price for the year, a mean value which is not technically the average value. It is sufficiently near the average, however, for our purposes, and these average values have been checked somewhat by comparison with the state valuations.

*Professor of Geology, Tufts College.

The statement that the average yield of a Michigan copper mine is close to 7 per cent. on the money invested may also be checked thus. The total assessments (money paid in on the stock marked thereon according to Michigan law) were $78,497,700 up to 1909 and the dividends $183,073,816. A mine, however, never begins to pay its dividends until four or five years after its organization and initial assessments. The most prominent dividend payers like the Quincy and Calumet have been paying for a long time, respectively since 1862 and 1870. These two alone are responsible for two-thirds of the dividends. Thus, without undertaking the colossal work of estimating the worth at an even date of all the assessments and dividends, it is clear that the dividends have certainly not followed the assessments on the average as promptly as if they were evenly distributed over the 28 to 34 years following organization. This would imply in the former case a return on the mine assessments of 7 per cent., in the latter case of 6 per cent.

Yield of St. Mary's After Listing.

The St. Mary's Canal Mineral Land Company was followed and succeeded by the St. Mary's Mineral Land Company, and, though by its holdings of copper stock this has become no more a purely land speculative company, it will be interesting to see the effect of listing and making a market for it. The opening of the Baltie lode increased very much the value of the company's property. Since 1903 it has received a steady income from the Champion Company. Accordingly, in 1901, a new company was organized with 200,000 shares at $20 a share, of which $6 went to each old share with a right to subscribe to one more, which sold at a premium. Thus the new shares made the old worth from $150 to $250, and, while this was during an epoch of inflation in the stock market generally, St. Mary's stock has never sold for less. Thus it can not be said from the stock market point of view to have been inflated. If we take the statement of the assets and liabilities in the first report of the St. Mary's Mineral Land Company and correct the value assigned to the holdings of the Champion mine stock from $19 to $67 or $80 a share to agree on a 7 per cent. basis with what it actually has yielded, we find the shares issued in 1901 were worth $42 to $55 a share on a 7 per cent basis. A share bought that year at the time of issue of the new stock would probably have cost about that figure. Computing the dividends for the next few years up to 1906, when say 10,000 more shares were issued, and supposing the stock were sold in 1906 at the price of the new stock which sold at a small premium, it would have been worth in 1901 $41.50, supposing that the intermediate dividends and the sale in 1906 had been discounted on the 7 per cent. compound interest basis; whereas if it sold for the high price that year it could have made much more. We see then that the yield after listing St. Mary's came down to a 7 per cent. basis something like other Michigan copper stocks.

Increment of Value Due to Marketability Similar for Stable and Unstable Securities (50 Per Cent.)

If the effect of listing and making a market for copper stocks is to reduce the yield from near 10 per cent. to 6 per cent. or 7 per cent., and, therefore, to increase the value by the same proportion, it is interesting to notice that the increase of value is in very nearly the same ratio as in the safer stocks already mentioned—guaranteed railroad stocks—as against mortgages. In the latter case the proportion is 42 to 63, or 67 to 100, instead of 69.8 to 100. It would seem fair to say that organized speculation increases the value of stock about 50 per cent., from which, of course, must be deducted the cost of the organization itself.

Fluctuation Factor.

Not closely dependent on volume of sales.—But whil the average effect of listing is thus given, it is not th same for all classes of stocks. This will come out bet ter as we study the next factor—the activity factor.

I at first attempted to analyse this by taking the vo ume of sales in 1899 (the first year given by Stevens and arranging the stocks in the order of the volum of the sales. I arranged them also to show the amoun of fluctuation. To show this fluctuation I divided th highest price of the year by the lowest, obtaining wha we may term the fluctuation factor. I was disappoint ed to find little apparent correlation between the vo ume of sales, if measured by number of shares sold, an the amount of fluctuation. Some mines of which ver few shares are sold have a wide range, others wher there is much sale have no range at all.

More closely dependent on price of stock.—But i must be remembered that the order of absolute num ber of shares was no sign of the order as to money in volved. Five shares of the Calumet and Hecla sellin at $500 or more is as great amount of activity, so fa as actual money is concerned, as five hundred share of a $5 stock.

For instance, in 1903 one of the most active stock was Allouez, of which there was 152,262 shares, a from $3.13 to $7.50 a share. This really involved n more money than the sale of 5,375 shares of Calume and Hecla at prices ranging from $550 to $400. I als plotted the weekly prices and sales of Copper Rang from 1903 to 1909, but no correlation was apparent.

If we rearrange the mines, however, multiplying th total sales by some figure that we shall take as a mea price (though it would be more strictly correct t take each transaction, multiply the number of share by its price and thus obtain the total amount of mone involved in the sales of the year) we find that the fluc tuation factor depends much more strictly on the pric of the share than the amount of sales, which, indeed may be neglected. The greater the price of the shar the less the fluctuation. Setting off in the table fo 1903 the names of the mines more or less to the righ according to their fluctuation factor, we find the mor expensive shares least set off.

Michigan Copper Stocks.

Fluctuation Factors and Sales in 1903.

1,226,030	2.03	Copper Range.
301,086	2.65	Centennial.
181,253	2.46	Winona.
152,262	2.40	Allouez.
120,526	1.87	Mohawk.
98,842	8.16	Arcadian?
83,419	1.84	Osceola.
67,078	2.70	Elm River.
65,717	6.00	Mass.
54,552	3.84	Wyandot.
52,925	6.00	Victoria.
44,485	3.50	Isle Royale.
34,087	2.14	Atlantic.
29,087	2.53	Michigan.
28,794	1.43	Wolverine.

23,377	2.08	Franklin.
15,239	2.53	Tamarack.
15,634	5.00	Mayflower.

15,815	5.00	Rhode Island.
7,505	4.50	Tecumseh.
6,438	1.58	Quiney.
5,371	1.37	Calumet and Heela.
4,582	3.80	Arnold.
2,240	3.33	Washington.

Division of Copper Stocks Into Two Classes at $10.00.

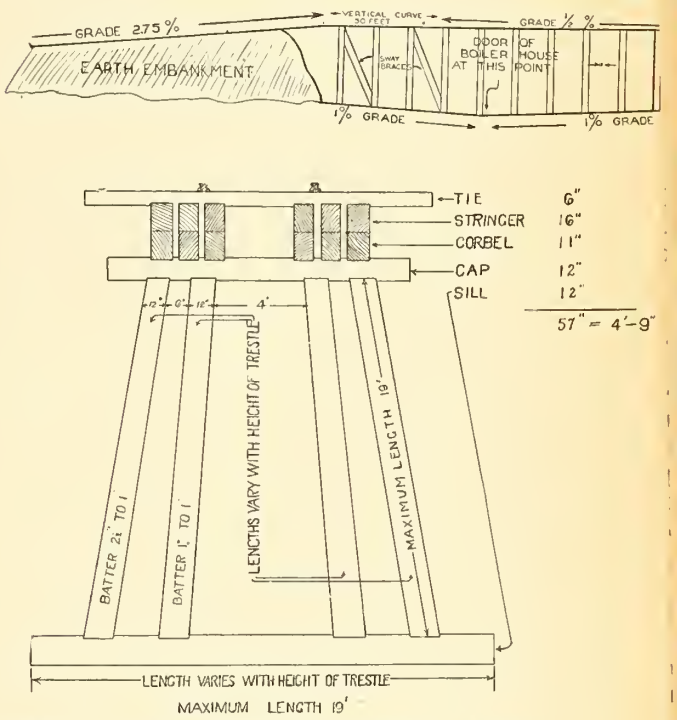
Class A.—Mines successful, dividend paying with average fluctuation factor 5/3. Rarely over 2.5.—In the table of sales for the year 1903 (where the mines are arranged in order of the number of shares sold, the fluetuation factor prefixed to each mine and the name indented in proportion to the range of the fluctuation faetor) I underscored those mines which in 1899 at no time sold below $10, and though I took this line arbitrarily I found I had with but one exeeption made a natural group (Class A). The mines which at no time sold below $10 in 1899 were with this exeeption all mines that had been proved to be able to produce eopper with profit, and they agree in several other striking features beside the fact that they did not sell below $10. Only the exeeption (the Arcadian) did not sell above $10 in 1901. This mine (the Areadian) was an illustration of a mine that at a time of frenzied boom was held at an artificial price through a whole year. In no other year was its lowest price above $10, and it has never paid any dividends or produced eopper to speak of or otherwise come into the class of the properties concerned. It should be excluded from the class, but I have not done so as it makes no qualitative differenee as to our conclusions. If one studies the mines of Class A one finds that the fluctuation factor averages 1.67 for 1899 (Bowen made it 1.631), and not only in that year, but in other years, it very rarely goes above 2.5.

(To be Continued)

SIMPLE COAL TRESTLE OF UNSQUARED TIMBER

By P. B. McDonald, of Negaunee, Mieh.

The accompanying sketehes show a coal trestle for use at mine boiler houses, to be constructed prineipally of logs. The grades of the rails for railway ears and the 1 per cent. grade of the floor to facilitate hai tramming the coal to the boiler house door, have bee found to be convenient in aetual installations. Swa braees, to prevent the bents toppling over like a ro of dominoes, are shown in two of the spaces. Plank may be nailed diagonally across each bent if desired and some engineers prefer to rest the sills at eithe end upon pieces of railway ties sawed into thre lengths. To obviate using corbels under the stringe which are 12 feet long, the stringers are sometime made 24 feet long, making joints upon alternate bents two double rows of stringers are run, one row makin joints upon even bents and one row upon odd bents over each bent the two rows of stringers are bolte together for greater security.



SIMPLE COAL TRESTLE OF UNSQUARED TIMBER

ELECTRICAL ACCIDENTS IN MINES: THEIR CAUSES AND PREVENTIONS

By H. H. Clark.*

Introduction.

One of the purposes of the work carried on by the Bureau of Mines is to make mining safer. For this reason the bureau is investigating the causes of mine accidents, the methods by which such accidents may be prevented, and the best ways of rendering aid to those who are injured or put in danger by accidents. This circular tells what are the chief causes of electrical accidents in mines, briefly points out the precautions that should be taken to avoid or prevent these accidents, and gives directions for treating persons suffering from electric shock or burns.

*Miners' Circular No. 5, U. S. Bureau of Mines.

Definitions.

To make this circular clear to persons not familiar with electrical matters, the following terms are defined:

Electric conductor.—An electrie conductor is something through which electric current may flow, just as a pipe is something through which water may flow.

Electric Circuit.—An electrie circuit is a system of electric conductors joined together so that electric current may flow through them, as water flows through a system of pipes.

Complete Circuit.—A complete circuit is one in which the current may flow freely, with nothing to stop it.

Current strength.—The strength of a current is its amount. A large current may be considered as stronger than a smaller one, because it has more effect upon man's body.

Alive and live.—Alive and live are terms that mean 'charged with electricity,' and are used in speaking of conductors, circuits, and machines that are in condition to give an electric shock.

Insulator.—An insulator is something that stops the flow of electric current, just as a dam stops the flow of water.

Voltage.—Voltage means electric pressure. Voltage causes electric current to flow, just as water pressure causes a current of water to flow.

Chances for Shock in Mines.

In handling live electrical machines or wires, or in working near them, care must be used to avoid getting a shock. This is especially true when the wires or machines are underground, because, as a general thing, there is little space, little light, and much dampness in a mine, and these are conditions which help to make electrical accidents possible.

The fact that the earth is used as a return circuit for the electric current places the miner in the position of standing upon one terminal of an electric generator; therefore, if he touches only a single point connected to the other terminal of the generator (such as the trolley wire, a metal part of a switch, a bare place on a mining-machine wire, or a live part of a motor) he is likely to receive a shock, the effect of which will vary with conditions from a severe jolt to a bad burn or even death.

General Causes of Shock.

A man's body is an electric conductor, although it is not as good a conductor as a trolley wire or a track rail, and current will flow through the body if it is made part of an electric circuit. The effect that such a current will produce depends upon its strength. The current may be so small that it can not be felt; it may be only strong enough to give a slight shock; it may be so strong that it will burn the body; or it may be strong enough to produce insensibility and death.

The amount of current which will flow through a man's body when it is made part of an electric circuit depends upon two things:

(1) The voltage or pressure of the circuit.

(2) The completeness of the contact between the man's body and the circuit.

Under the same conditions more current will flow from a large voltage than from a smaller one. A single-cell battery giving 1 to 2 volts can cause a current to flow through the body, but the current is too small to be felt. Much more current will flow through the body from contact with a 110-volt circuit. Such a current will give a slight shock. Contact with circuits of higher voltage allows even stronger currents to flow, and these give more severe shocks.

If a perfect insulator could be found, a man might stand upon it and place his hand upon a 500-volt trolley wire without receiving a shock, because the circuit through his body would not be complete and no current could flow. If a man should stand upon damp earth and handle a live trolley wire with gloves that were moist with sweat he would probably receive a severe shock, because a circuit would be completed through his body. If he wore no gloves the shock would be heavy enough to knock him down and might even kill him, because the circuit through his body would be still more complete. There are some men, but not many, to whom this last statement does not seem to apply.

It is most important to realize the extreme difficulty of so insulating the body that a circuit can not be completed through it. There is no such thing as a perfect insulator, although for practical purposes a number of things may be so considered. The most that can be done is to so insulate the body that the current which passes through it will be so small that no shock will be felt. The difficulty of doing this becomes greater as the voltage that is handled increases.

The most common voltages used underground are 110, 250, and 500 to 600 volts. The first voltage, which is used very rarely, is not hard to guard against, and the conditions under which it will give a severe shock are seldom, if ever, met. It is much more difficult to protect the body from 250 volts, and in working about circuits of 500 to 600 volts great care must be used in order to escape shock, especially when the earth is used as one side of the circuit, as it very often is in mine work.

Some Direct Causes of Shock.

Trolley Wires.

The reports of the mine inspectors of several States indicate that most of the shocks received in mines result from contact with trolley wires. These wires have to be bare of insulation, and they can not easily be shielded from passers-by throughout their entire length. A trolley wire must often be strung less than a man's height from the floor, with a track rail almost directly underneath it. Everything combines to make it dangerous to travel in the same entry with a trolley wire, especially if tools are being carried or things are happening that distract the attention. Great care is necessary to avoid shocks in crossing over trips of cars or entering or leaving them from the trolley-wire side. In such cases a man's head must pass close beside the wire at the time that his attention is given to watching his footing.

Accidentally Charged Equipment.

Next to contact with trolley wires, the most likely cause of shock is contact with parts of machines or equipment that are not supposed nor intended to carry current, but are accidentally charged with electricity. This charging is caused by the failure of insulation or by a live wire coming in contact with equipment. The frame of a motor or cutting machine or the iron casing of an inclosed switch may become alive and may then give as bad a shock as a trolley wire. Such a condition is especially dangerous because it is unexpected.

The frame of a locomotive is usually so completely in contact with the track rail that a man can not get a shock by standing on the rail and touching the locomotive, but this may not always be the case. If for any reason there is a great deal of sand on the rails the locomotive frame may be almost completely insulated from them. In that case a shock may be received from the locomotive frame or the draw-bars of cars coupled to the locomotive.

Other shocks are caused by contact with those parts of equipment that are known to be alive but are touched by accident while handling apparatus or repairing it. This applies to connections made to the trolley wire while it is carrying current, to the ad-

justment of motor brushes, and to all repairs made to pparatus that is alive.

Precautions.

The best way to avoid electric shock is to show due espect for the electric current. Indifference to the angers of electricity does not indicate courage or isdom, but poor judgment and ignorance. The fact hat a man does not get hurt when he is careless in andling electric wires does not prove that he is leverer than other men, but rather that he is more ortunate. The worst feature of such acts is the bad ffect that they have on those who see them or are old about them. Those who know about electrical pparatus and are employed to handle and repair it hould try to teach others to be careful instead of encuraging them to be careless.

The only sure ways to escape shock are to keep way from the trolley wire, especially when carrying ools; to avoid touching electrical machines unnecesarily; and to provide and use some means of insulatng the body when making repairs on electrical aparatus. If there is a way to cut off the current from pparatus the current should be cut off before the pparatus is handled. If it is necessary to work on pparatus that is carrying current, every precaution hould be taken to insulate the body from the ground.

It is impossible to tell whether conditions are safe nless the workman has made them so himself. No ne can tell by merely looking at a motor whether or ot the parts that carry current have come in contact ith the frame of the machine. A workman can not e certain whether the place where he must stand to epair live apparatus will sufficiently insulate his body om shock. The only way for him to be safe is to rovide something suitable to stand on while making epairs. In doing this he should remember that dryess is the most desirable quality. Dry boards, free om nails, are good for the purpose.

Rubber gloves or leather gloves in good condition nd without metallic fastenings will protect the body om shock. If the rubber covering of the gloves is orn thin the gloves give almost no protection. The me is true of leather gloves that are damp with ater or sweat. Rubber boots without nails in the les or heels are good protection when new, but if e soles are worn or cracked, their insulating value doubtful.

The position of the body is an important matter in ndling apparatus that is carrying current. If a an has merely to make some adjustment he should se but one hand, if possible. He should also try to lace his body so that the involuntary recoil from a ssible shock will remove his hands from the apratus instead of causing them to grasp it.

The use of rubber tape on the handles of pliers, rew drivers, and wrenches can not be depended on nless the tape has been freshly and carefully apied. Rubber coverings for the handles of such tools e a protection if the coverings are new and in good ndition, but even then the chances are great of uching the hand or the fingers to an uncovered part. nsulated tools should not be trusted to give entire rotection.

There is one practice that can not be condemned too verely, and that is the wilful giving of electrical ocks to others. This may be done impulsively or ay be deliberately planned, but it is always dangerus. The effect of such a trick can not be foreseen ecause there are so many things to consider. The person who is given the shock may be so placed and so constituted that serious and even fatal results will

Explosives and Electricity.

Great care should be used in handling explosives near electric current. It requires only a very small electric spark to set off powder. An exceedingly small current passed through the powder itself will explode it.

In carrying explosives in mine cars care should be taken to keep the packages off the floor of the car and away from the iron fittings, as these frequently receive current from the draw-bars, especially when the motorman is using sand on a slippery rail. Packages of explosives should be kept closed, and should not be taken into cars that are near the locomotive, as sparks are often thrown down from the trolley wheel.

The safest thing to do is to keep explosives as far away as possible from all electric current. If explosives must be handled near the current, use every precaution to protect the packages.

Some Suggestions.

The following suggestions given below, will help to lessen the number of electrical accidents

(a) Suggestions for Mine Foremen.

Don't allow explosives to be carried in cars near

Don't allow inexperienced men to handle electric wires.

Don't fail to protect the trolley wires at crossovers and partings.

Don't allow wires to be installed in a slipshod manner.

Don't fail to have wires promptly repaired after roof falls.

Don't allow explosives to be carried in cars near the locomotive.

(b) Suggestions for Electricians.

Don't fail to set a good example for less experienced men to follow.

Don't work on live apparatus if it is possible to cut off the current.

Don't stand directly on the ground and work upon live apparatus of any kind—get something dry to stand on.

Don't rely upon gloves for protection, unless they are perfectly dry, free from holes, and without metal parts.

Don't, under any circumstances, work on live apparatus that is charged with a voltage greater than 650 volts.

Don't handle wires carelessly just because they are insulated.

Don't send an inexperienced man to work on or about live apparatus.

Don't neglect to inspect your equipment regularly.

Don't ever cause anyone to receive an electric shock.

(c) Suggestions for Miners.

Don't think that it is smart to get an electric shock. Every time a man gets a shock it shows that he has been lacking in care or knowledge.

Don't be ashamed to be careful. You owe this not only to yourself but to others who may follow your example.

Don't handle wires or electrical apparatus of any kind unless you are told to do so.

Don't get off or on trips from the trolley-wire side.

Don't carry tools on your shoulders when crossing under the trolley wire or when travelling in the same entry with it.

Don't travel in the same entry with the trolley wire if you can avoid doing so.

Don't get your explosives near electric wires.

Don't allow packages of explosives to come in contact with the metal parts of cars.

Don't carry explosives in cars near the locomotive.

Don't ever cause anyone to receive an electric shock.

Don't ride on electric locomotives.

Don't fail to report when you find that electric wires are down.

Don't install temporary lights — leave that work to the electrician.

Treatment for Electric Shock.

When a man has received an electric shock that leaves him senseless, two things should be done as soon as possible.

First, remove the victim from contact with the electric wire.

Second, rivive him or "bring him to," by getting him to breathe.

While removing the victim from the electric circuit, be careful not to get a shock yourself. If there is a switch right at hand, cut off the current at once; but if there will be any delay in cutting off the current, remove the body from the circuit by means of a piece of dry wood, used either to roll or push the body aside or to lift from the body whatever is carrying current to it Tools with dry wooden handles, such as picks or axes, may be safely used for this purpose.

The body of the victim can be safely grasped if your hands are protected by several thicknesses of dry cloth, or if you stand upon a piece of dry wood.

When you can do nothing else, you may be able to short-circuit the line with which the victim is in contact, and thus blow the circuit breaker or fuses which protect that part of the electric system.

A short circuit may be made by placing an auger or drill or a piece of pipe so that it will connect the two sides of the electric circuit. For example, in case the victim is in contact with a trolley wire, the auger, drill, or pipe should be thrown across the trolley wire and track rail, so as to be in contact with both. In doing this, be sure that the auger, drill, or pipe leaves your hand before it touches the current-carrying part of the circuit, as otherwise you will get a shock yourself.

When the victim has been removed from contact with the current, turn him on his back, loosen the clothing from around his neck, chest, and abdomen, and place a small log, a rolled-up coat, or something of similar size and shape under his shoulders in such a way as to throw his head back and his chest up.

The next thing to do is to draw out the victim's tongue, which can best be done by grasping it with a piece of dry cloth. This act clears the windpipe, and unless it is done, the victim can not be made to breathe. If the rescuer is alone, he will have to keep the tongue in this position by tying it with a handkerchief or a bandage passed over the tongue and under the jaw.

The tongue must be held in this position while giving artificial respiration.

There are several methods of giving artificial respiration, but the one most commonly used is the Sylvester method. Kneel behind the head of the victim, grasp the forearms just below the elbows, and dra them slowly backward until they are extended as f as possible over his head, and hold them there f about one second.

Then slowly push the elbows forward and dow ward. Next press the chest and hold them there f about one second so as to drive out the air from t lungs.

Do not perform these movements hurriedly; pum ing the arms up and down is a waste of time. To co plete one series of movements should take about fo seconds. A very good way to time yourself is count, very slowly, "one, two, three, four," wh making the movements. Count "one" as the victim arms are being extended, count "two" while they a being returned to his side, and count "four" wh exerting pressure on his chest.

Usually a victim of electric shock can be made breathe within an hour, and the artificial respirati should be continued at least that long, even if t patient does not show any signs of being "broug to."

If other persons are at hand, have them assist relieving you at short intervals, and have them ke the victim warm by covering him with coats or an thing else that may be at hand. After the victim l gins to breathe, the assistants should rub his lim briskly and toward the heart, keeping their hands u der the covering while doing so. This will help restore the circulation of the blood, which has be for a time suspended.

While arrangements are being made for removi the injured man to his home or to a hospital, tre any injuries that the victim has received. Treat el trie burns exactly as ordinary burns. Before the a rival of a doctor it is proper to cover the burnt pla with several thicknesses of picric-acid gauze. Th gauze is now being used in nearly all mines and ho pital emergency rooms.

In case no picric-acid gauze is at hand, the bur may be covered with clean gauze, preferably tak from sterile packages, and covered with vaseline, ea bolized vaseline, olive oil, linseed oil, or what is knov as carron oil, which is a mixture of linseed oil a lime-water.

Cover these dressings with plenty of cotton a protect this in turn from the outside air with oil paper or anything that will keep out the air wh the victim is being taken home or to a hospital.

Bandage all dressings lightly, so as to cause as l tle pressure as possible upon the injuries.

Magnesia rarely occurs in brick clay in larger p portions than one per cent.

A convenient item in the prospector's equipment the oiled silk tent. For the man who is travelling h himself, or with but one companion, the canvas te is heavy and cumbrous. Light loads mean a great de to the man who has to cover virgin territory.

The care of belting for power transmission is a mo important factor in industrial establishments. Th individual electric motor drive has not displaced t belt drive. The mathematics of the question have n been fully developed; but it is known that the tensi is an extremely variable quantity, a quantity affect by atmospheric moisture, by the age of the belt, a by other uncontrolled factors.

High Grade Ore Deposits of the Portland Canal District.

(By an Occasional Correspondent.)

There are fashions in mining as in millinery. The ublie favour turns from Cobalt stocks to California d with as little apparent reason as is incident to a hange in style of bonnets. A leaching process is in ogue, and every mine manager tries to apply it to is partieular problem until some new 99.99 per cent. rocess supplants it. It is interesting to watch some chnieal term making the rounds of the trade and ientific publications. For some time in this district ie low graders have not only held the centre of the age, but have pretty well monopolized the whole ow, more capital having been found for their exloitation — the usual undiscerning human deference large expenditures of money. Disparaging refernces to "high assays" have been fashionable. Even ie Provincial Mineralogist seems to have fallen in ith the popular mood. In the last annual report of ie Minister of Mines, he says: "The camp contains a rge number of properties from the prospect workings which exceptionally high assays have been obined, giving rise to unwarranted hopes and statements which can not be borne out on a strict examiation. . . . In the opinion of the writer this porion of the camp will be comparatively low grade conntrating propositions, from $10 to $20 ore, the high ade minerals being difficult to concentrate and not fficient in quantity to dispense with this process." It ould be singular if a large number of properties elded exceptionally high assays without here and ere a workable deposit of high grade ore. In view the fact that the Provincial Mineralogist visited ne of this class of properties, and that at the time of s visit none of the low grade properties had repaid cent of their large capital expenditure, his statement manifestly unfair and wholly unwarranted, and it the purpose of this article to remind the investing blic that the ores of Portland Canal are not all low ade; that the initial expense of operating high grade operties is negligible in comparison with the cost of cessary equipment for exploiting low grade ore; and at it is by no means proven which class of properties this district will develop the best dividend payers.

In an inhospitable country where the economic pressre is greater than in the Coast district, no doubt conderable ore would have been produced from discovies of equal promise. But living is easy on the Coast, e prospector has been pessimistic regarding his disveries or inexperienced as to economical methods of ploiting them; transportation difficulties have been eat, and so he has preferred to sit back and wait for e boom and the capitalist, rather than take the risk mining and brave the winter's snows in the lonely nyons of the hills. Now that transportation facilis have been greatly improved and the stock market no longer an Aladdin's Lamp, it is probable the sucding years will see shipments of high grade ores of creasing commercial importance.

I include under the head of high grade ores, all es that can be brought to market at a profit without eliminary treatment and by a primitive mode of nsport — in short, "rawhide" ores. The minimum say value of such ore under present transportation cilities would be in the neighbourhood of $50 per ton. ere are a considerable number of properties in the district, silver-lead chiefly, that belong in the rawhiding class. Among them may be mentioned, on Glacier Creek, the "Lakeview," the "Francis," and the Rush-Bagg-Nelson group; on American Creek, the "Bonanza." The Lydden and Eusch claims and the holdings of the Northern Terminus Company. The "Mountain Boy" carries lenses of splendid ore along with large bodies of concentrating material. At the Northern Terminus a trail has been built to the Red Cliff to connect with the railroad; ore is being sacked and a camp is being equipped for mining and rawhiding ore during the winter. On Salmon River, Seattle parties have been doing quiet but effective development work on a grey copper property belonging to Linderbourg Bros. High grade ore is also reported from the Upper Salmon, Bitter Creek, and Upper Bear River. This list does not pretend to be complete.

Tunnel and Ore Dump, Excelsior Mine.

Among the high grade properties of the district the Rush-Bagg group of claims, situated between the north and south forks of Glacier Creek, occupies a place of leading importance by reason of their extent, values, and advantageous position. With this section the writer has considerable familiarity, and a discussion of its characteristics may be of interest. Rush and Bagg's main camp is reached by horse trail 3½ miles from the Portland Canal mill. The "Ben Bolt" mine, Sir Donald Mann's property, uses the same trail for 2½ miles. The camp is situated at an altitude of 2,000 feet in a heavily timbered cleft in the hills, on the

banks of the Middle Fork. R. G. McConnell describes this section as a region of basic intrusives. For a cursory examination this is as accurate as could be expected. It will be found, however, that the main structural differences between this section and adjacent country are: (1) the entire absence of granite; (2) smaller areas of argillites and larger areas of intrusives; (3) the presence of a bluish to greenish siliceous limestone that blends into the intrusive and may be mistaken for it. The intrusive will usually be found to be a diabase. A basic porphyrite occurs, probably formed from the same magma. Successive bands of slate (argillite) show the formation to be regular, striking and dipping as in the adjacent country. Faults are unusual. Quartz veins frequently accompany the slate bands, carrying ore similar to that found in the Ben Bolt and Portland Canal mines. Veins of this class are found on the "Sentinel" and "Jupiter" claims. The whole region is criss-crossed with barren or sparsely mineralized quartz veins, without any regularity of strike or dip. Ankerite occurs but is not important as a gangue. Rusty "blowouts" are common, especially on the Excelsior and Eagle claims.

Upper Tunnel, Evening Sun Mining Co.

But it is the high grade veins in which we are particularly interested. These veins invariably cross the formation and dip at a steep angle. They divide themselves into two classes: (1) Siderite veins (striking N.E.). A vein of this class is found outcropping on both sides of the creek at Rush & Bagg's camp. It has been traced down one hillside and up another, through the "Columbia," "Evening Sun," and "Silver King" claims. The vein is very regular, free on both walls, and up to 10 feet in width. The gangue consists of siderite, quartz, and sheared country, softened and transformed by mineral solutions. The sulphides, pyrite, arsenopyrite, galena, zinc blende, stibnite, and grey copper are disseminated throughout the vein, and are frequently found concentrated in lenses and shoots of solid sulphides, varying from clean ore to combinations of every degree of complexity. The chief value of the ore is its silver content, which is found associated with galena, zinc blende, and what is locally called "grey copper,' probably freibergite. The last-named mineral has been found, when pure, to assay up to 3,950 ounces silver per ton. Two 75-foot drifts have been driven on the Evening Sun, and a 35-foot drift on the Columbia — far too little work to prove the ground when the capricious nature of high grade silver deposits is considered. One tunnel shows better ore than the surface, and the other two vice versa. On the Silver King the same vein has been opened up by three tunnels, two of which have developed shipping ore. A spur vein on the Evening Sun is 5 feet wide and shows a strong shoot of the usual character of ore.

The Excelsior, situated one mile east of the Ben Bolt camp has two similar veins or vein systems about 1,000 feet apart. The south vein has about the same width as the Columbia vein, and has been traced upwards of 1,000 feet, outcropping for about half that distance. It is not so regular as the Columbia vein but its ore and gangue are almost identical. There are several tributary veins, two of which at least carry high grade ore in some quantity. The development

Open Cut, Columbia Mining Co.

consists of a number of open cuts and trenches and two short drifts, one on the trunk vein and one on a spur. The north vein is rather a wide vein zone with successive parallel lenses of ore and spurs into the adjoining country. It has been traced 400 feet by a line of outcrops connected by float. Beside the usual ore and gangue there is considerable chalcopyrite. Development is limited to a series of open cuts.

(2) Quartz veins (striking N.W.). On the Katherine claim of the Rush-Portland Mining Company, a vein of this class has been traced some 500 feet, varying in width from 1 to 5 feet. The mineral content of the vein are similar to those of the siderite vein with the exception that there is less lead and antimony and more arsenic. A tunnel has been driven on the vein for 110 feet, developing throughout its length ore similar to that found on the surface. A small tri

shipment has been sacked that samples $160 per ton in gold, silver, and lead. The same company has a similar vein on the Elsie claim on the opposite side of the ridge. This vein appears to carry some native silver in a finely divided state, in addition to the usual sulphides. The lowest opening shows 3 feet of quartz with heavily mineralized paystreaks, along both walls. A drift has been started. The convergence of this vein, with a tributary just after the vein leaves the bluffs and disappears under the talus, makes it appear probable that the best of the vein is covered. Two strong veins outcrop on the Ne Plus Ultra claim, but they have not been prospected even superficially.

Lack of funds has hitherto prevented the companies operating in this section from doing any considerable amount of exploratory work, but enough has been accomplished to demonstrate the existence of rawhide ores—"Slocan" ores in some quantity. Any person who is well informed regarding the Portland Canal district, knows that such ores are of rather frequent occurrence throughout the camp. When a fraction of the money that has been spent here on low grade ores has been used in developing these high grade deposits, it will be early enough to pass judgment upon their value.

NOTES ON MINERALS FOUND IN THE SLOCAN DISTRICT, B.C.

The following paper was prepared by Mr. Wm. Thomlinson, of New Denver, B.C., and read at a meeting of the Western Branch of the Canadian Mining Institute, held in the Slocan Lake District last September. Mr. Thomlinson stated, in his introductory remarks, that he intended to deal more with some things not generally known concerning the mineral occurrences of the Slocan, than with the ordinary commercial ores of the district. He then proceeded, as under:

High-Grade Silver Ores.

As the high-grade character of the silver-lead ores of the Slocan is now so well known, I shall refer but briefly to these, for my chief aim now is to give information relative to other minerals also found in the district.

First, though, I would mention that I think the high silver content of both the silver-lead and the "dry" ores of the district is due mainly to their containing freibergite, or grey copper, a variable and complex variety of tetrahedrite, which is, in this district, usually rich in silver. Other high-grade silver minerals, such as argentite and pyrargyrite, also occur in the ores, but, I think, are not generally so important as the freibergite. As examples of ores rich in silver I give herewith analyses of two samples of freibergite from the Slocan Star mine, situated near Sandon:*

	Sample A.	Sample B.
Silver, per cent.	19.57**	15.14***
Copper, per cent. ..	14.57	11.27
Zinc, per cent.	10.53	8.15
Iron, per cent.	7.51	5.81
Antimony, per cent..	22.91	17.72
Sulphur, per cent....	24.91	20.13

*From the "Report of the Commission Appointed to Investigate the Zinc Resources of British Columbia, Mines Branch, of the Department of the Interior, Canada, 1906."

**A—19.57 per cent. silver equals about 5,706 o per ton of freibergite.

***B—15.14 per cent. silver equals about 4,415 o per ton freibergite.

Zinc Ores.

As to the zinc ores of the district — sphalerite, o blende (sulphide of zinc) is practically the only zi mineral found. It occurs in considerable quanti associated with all classes of silver and silver-lead and is seldom of shipping grade as crude ore, or out having first been concentrated. Much of th of the Lucky Jim mine is a notable exception, a paratively large quantity of this ore averaging than 50 per cent. zinc, having been shipped in its c state.

Other Minerals.

Regarding other minerals found in the Slocan, shall, for the sake of brevity and clearness, place the under subheads, as follows:

Gold.—A majority of mining men and the gener public outside of the district think there is no gold "the Silvery Slocan." To some extent this is a mi take. Fine specimens of free gold have been found c claims situate on Lemon Creek, and samples of di ore from Springer Creek, Eight-mile Creek, Four-mi Creek, and the north fork of Carpenter Creek, hav been found to run high in gold. Two cars of ore fro the Kile group, on Lemon Creek, gave smeltery r turns of nearly $80 per ton in gold. About 15 yea ago two prospectors shipped from a prospect on Eigh mile Creek five tons of gold-bearing quartz, which shi ment was made in my name, so that I can vouch fo the accuracy of the statement that the returns re ceived from the smeltery showed a gold content of value of $125 per ton.

In the Slocan gold occurs chiefly in the dry ores, bu there has been one prominent exception within the si ver-lead producing area of the district, for at th Monitor mine, near Three Forks, carload lots of silve lead ore were found to contain as high as $15 per to in gold, and even the zinc concentrate of ore from thi mine assayed from $2 to $12 per ton in gold.

Silver.—The principal silver minerals of the cam are: (1) freibergite, (2) pyrargyrite, and (3) argen tite; their importance being, I think, in the order her given. These minerals are often found in a decom posed condition, as dark stains, or powdery masses i the vein gangue or selvage. In such cases the term "black sulphurets," or simply "sulphides of silver," is used. Alteration of freibergite or grey copper usu ally gives green and blue stains through the ores and in most cases, these indicate the presence of much sil ver, especially in the so-called dry ores.

Chlorides and bromides of silver are said to occu here, but I have never seen these minerals in the dis trict, so, like the Scotsman, I "hae ma doots"

Native silver occurs at many places, especially i the dry-ore belt, from Four-mile Creek southward t Lemon Creek.

Fine specimens of arsenical ruby-silver ore (prous tite) have been found on prospects on the north side of Ten-mile Creek, and from the same claims speci mens showing cobalt bloom (erythrite) can be ob tained.

Lead Minerals.—Of course, galena, the sulphide of lead, comes first, as it is the main lead mineral of the district.

The secondary lead minerals, carbonate of lead (cerussite) and sulphate of lead (anglesite) are not plentiful, although the carbonate ore does occur in shipping quantities.

The hard, clear, crystalline variety of carbonate is rarely found here, the commoner form being as granular or powdery masses intermixed with oxides of iron, gangue vein matter, etc.

Zinc Minerals.—As already stated, blende, the sulphide of zinc, is the only zinc mineral of importance found here. In the Slocan, as elsewhere in the northern corner of North America, the secondary zinc minerals appear to be almost entirely absent. Whether these ore deposits in this part of America are of comparatively recent origin or the climatic conditions have been unfavourable for the alteration of the sulphide to carbonates and silicates of zinc, I shall leave to abler men to determine.

Copper Minerals. — Copper minerals occur here, but, to date, no ores of copper have been produced. However, there are great possibilities, even in this direction, especially on Eight-mile Creek, south of Silverton.

Yellow copper (chalcopyrite) occurs all over the district, and associated with all classes of lead, silver, zinc, and gold ores. In the dry ores, yellow copper is closely associated with the grey copper, and at the Arlington mine, on Springer Creek, yellow copper served as an indication of the presence of high-grade silver ore. I have noted a similar connection in ore from the Standard mine, on Four-mile Creek, near Silverton. Some specimens show chalcopyrite enclosed in freibergite, these associated metals occurring as eye-like inclusions in the galena.

Secondary copper minerals are not plentiful in the district, although green and blue stains — carbonate of copper — are often seen in the local ores, resulting, I think, from the alteration of the copper-bearing freibergite. On Eight-mile the secondary copper minerals, malachite, azurite, and cuprite, are conspicuous along the outcrop of a large mineralized zone of eruptive rock. In this zone, chalcopyrite, iron pyrite, and, I believe, nickel-bearing pyrrhotite, are also found. Some good specimens of carbonates and red oxide of copper can be obtained here, and they give clear proof of their secondary origin, as they occur on or near the surface of the mineralized rocks, and are found containing inclusions of twigs, roots, pebbles, etc.

Iron Minerals. — No ores of iron are found here, but pyrite, pyrrhotite, and oxides of iron are all closely connected with the local ore deposits.

Vein Fillings. — In the silver-lead producing area the vein material is usually quartz, calcite, and siderite, with graphitic rock and talcose-clayey selvage. Veins in the granite or grano-diorite area have a filling of quartz, feldspathic rock, calcite, and siderite, also with a clayey-talcose selvage.

Antimony.—Stibnite, the sulphide of antimony, occurs at several places in the district, the largest deposit yet found being on the north fork of Carpenter Creek. A car lot of high-grade antimony ore was shipped from there a few years ago, when antimony was selling at 25 cents per pound. The property from which it was taken is not at present being worked.

Molybdenum. — Molybdenite (sulphide of molybdenum) is found in small quantities at half a dozen or more places in this district, but the deposits have not yet been developed, or even examined closely.

Tungsten. — Scheelite (calcium tungstate) has been found at the Meteor mine, on Springer Creek. The occurrence is small, but this mineral may have been frequently overlooked in properties near the Meteor, in the same granite formation, owing to the resemblance of the pinkish-coloured scheelite to the inclusions of reddish feldspathic rock in the veins there.

Other Minerals.—I believe that some nickel and cobalt minerals occur on Eight-mile Creek, but cannot yet speak with certainty as to this.

Native arsenic and arsenopyrite are found on the L. H. group of claims, situated on Red Mountain, south of Silverton, and here, as elsewhere, gold is associated with the arsenical iron.

Heavy spar, barytes, sulphate of barium) occurs at two places on Four-mile Creek, in one instance closely associated with lead ores, on the Robin claim, near the Standard mine.

Both fluorite and kaolinite are found near The Mountain Chief mine, about two miles from New Denver.

As an illustration of the fact that the mineral possibilities of this old mining camp are not even yet fully known, I may add that during a quite recent prospecting trip in the granite area, I looked over two unworked mineral claims, and on one I found huelandite, a member of the zeolite family of minerals, while on the other I found tourmaline, a well-known associate of tin ores.

A brief discussion followed the reading of this paper, and Mr. Thomlinson was complimented upon the instructive and interesting nature of the information he had presented before the meeting.

Cuban Iron Ore Deposits

Written by Dwight E. Woodbridge.*

On the north coast of Cuba there are iron ore deposits in the nature of laterites, amounting to something more than 200,000,000 tons. Six years ago the existence of these ore bodies was not known. They lie in the Province of Oriente, near the east end of the island, and adjacent to the sea. They are owned by various steel-making interests in the United States, and one of these steel-making concerns is using about 1,000,000 tons of this ore a year in the manufacture of high-grade, low phosphorus nickel steels.

This north coast Cuba iron ore is peculiar in several respects. It is a brown ore, high in moisture and alumina, very low in silica, with practically no phosphorus, and carries about .7 per cent. in nickel. These ores are upon the top of the ground; that is, they form the soil, and the average thickness of the ore beds is

*Mining Engineer, Duluth.

ot far from 20 feet. They are nowhere distant more an ten miles from the sea. All of these considerations ake them of exceptional value.

Let me emphasize the fact that no surface of soil xists over these ores; that, indeed, the ore itself is he soil, upon which grow either pine forests or a haracteristic tropical jungle. On the lower elevations nd in the better drained of the upland interior, pine redominates; inland, where the rainfall may be heav-r, and wherever it remains more persistently after alling, the verdant jungle enters. It closely resem-les the jungles of northern South America, with its

posed entirely of this material, it is usually carried in a matrix of soft ore, and it was the original design, at the time of discovery, to wash this hard ore from the surrounding red soil and ship a product of indurated iron ore. This scheme was impracticable. During the course of experiments having in view the washing of this material, it was found that the soft matrix was as good as the hard ore, and when this fact was fully realized the great size and vast importance of these deposits were appreciated and their possibilities were realized.

Mining Iron Ore by Steam Shovel, Mayari Fields, Cuba.

ough, cord-like creepers, its strange arboreal growths, nd its dense poisonous and prickly shrubbery. It is ard to penetrate unless one has in his hands that mnipresent weapon, the machete. In the belief that thin capping of surface-soil and humus might lie bove the ore in these jungles, I took many samples n these woods at varying depths, which showed on nalysis that, when found at all, the ore extended to he surface, whether it was timbered or not. No strip-ing of these ore bodies is necessary to fit them for ining, and during the dry seasons a lighted match ay be applied to the forest-floor and the fire will lean off all organic matter above the ore, leaving it ree and fit for immediate mining by the steam shovel r other means of excavation.

A typical analysis of these ores dried at 212 degrees, is about as follows:

	Per cent.
Silica	3.37
Fe	43.67
Al_2O_3	13.07
Cr	1.745
Ni, Co	0.8025
P	0.008
S	0.107
Combined H_2O	11.59

Hygroscopic moisture varies with the seasons, but may average about 15 to 20 per cent.

Loading and Nodulizing Plant, Mayari

Scattered about the surface of these deposits are boulders, flat sheets, pellets, and nodules of hard iron ore, somewhat dehydrated, and varying from masses of many tons to pieces the size of minute bird-shot. Natives call the pellets "shot-soil," a name warranted by their appearance and by the use to which they sometimes have been put, both in peace and in war. While the upper inch or two is occasionally com-

About two years ago the Pennsylvania Steel Company began smelting these ores, after an investment of several million dollars in railway, beneficating plant, piers on Nipe Bay, etc. It found the ore admirably adapted to all uses which an ordinary low phosphorus ore might be put to, and, furthermore, found that the nickel alloy gave the steel greatly added strength and elasticity. Up to the present time the major portion

of shipments have been nodulized ores, but the company is now shipping ore in its natural state more heavily than before, and is operating a large blast furnace exclusively on the raw ores. This company is the chief owner of these north coast Cuban ores, having a tonnage variously estimated at from one thousand million tons upwards.

During the last four or five years very extensive explorations have been carried on in these ore bodies I was in charge of an exploration that measured and tested grades on some 750,000,000 tons, no slight addition to the world's reserves. By reason of the character of this ore the process of exploration is unusually rapid, simple, and cheap. As has been said above, the ores are claylike, and the walls stand remarkably well. Pits dug several seasons ago still show on their vertical sides the marks of the pick. In exploration the ore is bored by an ordinary two-inch auger-bit, that is driven down by hand. These bits are forged on the end of a sectional rod some four feet long. As a hole is driven down additional threaded sections are screwed on the rod, making it any desired length. On each end of each rod, except where the bit is shaped is a backing-nut screwed down hard, in order to prevent the rods from working too tightly into the sleeve nuts when turned into the resisting ground. In most cases ore can be bored by this simple tool with comparative ease, and when hard blocks and boulders are encountered underground, they are sometimes cut by the substitution of a cutting chisel-bit for the auger point; in other cases the men will move a few feet away and drive another hole, experience having shown that a very short distance will usually be sufficient to avoid a boulder. The hole is started through the drift top soft ore or nodules on the surface, a little water is poured in, the bit lifted and driven down by the combined strength of two men, and then turned in the ore. The work is a combination of churning and boring. Every few feet the tool is lifted, the ore adhering to the bit is cleaned off by pressing a stick into the point of the bit and revolving the tool, and saved for analysis, and all sludge that has collected above the bit is scraped off. If the hole is sampled in sections, all ore taken out of each section by the bit is saved to make

On line of Railway from Mine to Harbor

A Railway Bridge

a full sample; but if the hole is sampled as a whole, the ore is all piled upon a cloth and afterwards mixed and quartered down with the ever-ready machete to make a suitable sample. The drilling is hard work in deep or difficult holes, or where nodules are frequent —as hard as any labour that a man can comfortably endure. It is done almost entirely by Spaniards, mostly from the Province of Galicia, who become very expert and earn good pay.

The presence of nickel and chromium has been shown in the analysis noted. The former is found in quantities increasing towards the floor of the deposits. In my own analyses of several hundred samples for this element, the highest percentage found was 1.28 per cent., and the lowest 0.44 per cent., with an average not far from 0.80 per cent. I need not emphasize the economic importance of an iron-ore averaging 43 per cent. of iron, and carrying 0.80 per cent. of nickel. Several hundred tests from chromium showed an average of 1.75 per cent., a serious matter if it were not that a simple metallurgical process will eliminate this element at one stage of the reducing-operation. These ores are of Bessemer grade, lower in silica than the average Mesabi, and not higher in kaolin than some Mesabi ores. Phosphorus exists in very slight proportion. Sulphur is negligible. The high alumina adds to fluidity in the blast furnace and assists reduction. At Felton, on Nipe Bay, the Spanish-American Iron Company, operates a large works for the beneficiation of this ore by drying it in cylindrical, rotating, horizontal kilns heated to a high degree, which reduces, by 33 per cent., the weight of raw ore charged. Against this cost of nodulizing, which may be given at about $1.25 per ton of product of the kilns, are to be placed the saving in freights and duty, and the advantage to the furnace-man of receiving for treatment a partly-prepared material.

With no over-burden to be removed, the deposit situated close to the sea, with stream-valleys cutting through the ore-beds and running directly to deep water, and with an average thickness suitable for about one shovel-cut, these ores should be mined at low cost by ordinary steam-shovel, or drag-line excavator. One block of 75,000,000 tons, assaying several percentages better than the average of the district and of a thickness of about 70 feet, can be connected with deep water by a railway 4,000 meters long, without excessive gradients. Ore so situated can be delivered on board ship at an actual operating cost not to exceed 20 cents per ton. The average cost of mining and rail-transport to the sea for the entire tonnage in sight should be but little more than this amount, if operations are conducted on a scale of magnitude commensurate with the importance of the undertaking.

It is interesting to make comparisons with this ore and that of the great Mesabi district of Minnesota. Cuba has the advantage in known tonnage, 2,000,000,000 tons, against, say, 1,500,000,000 known on the Mesabi. But the latter is not yet completely explored, and half a billion tons more may be found. With water extracted the ores are of nearly the same percentage of iron, with a slight advantage in favour of the Mesabi. The latter is both bessemer and non-bessemer, with its average phosphorus 8 to 10 times as high as this Cuban ore. Mesabi ores lie from 20 to 150 feet below the surface, while those of Oriente pro- are 80 cents a ton to Lake Superior, 60 cents from lake ports to Lake Erie, and $2.60 more if the ore is taken to Atlantic ports. These Cuban ores can be gotten to the sea at a transportation charge of 10 cents, and an ocean freight of 70 cents will take them to Atlantic American furnaces, or $2 to British ports. The Mesabi range will have shipped to the close of 1911 a total of about 250,000,000 tons at a profit of, say, about $350,000,000, including royalties. The north Cuban mines are beginning what is doubtless a most important career.

While these are not the only irons in Cuba, they are, naturally, by far the most important. Mining has been under way on the Caribbean Sea, near Santiago de Cuba, for many years, by the Pennsylvania and Bethlehem Steel Companies, and until the discoveries on the north side these Santiago mines were the chief source of supply for those companies. These are hard, high-grade ores, and are in comparatively limited quantities, though probably many million tons remain to be mined.

Estimates of the total iron ore reserves of the world are, for a tonnage, reduced to metallic iron, amounting to 10,000 million tons. Of this these new north Cuban reserves constitute about 8 per cent.

PROPOSED BASIS OF SETTLEMENT OF COAL MINE STRIKE IN ALBERTA AND EASTERN B.C.

The District Ledger, which is the official organ of District No. 18, United Mine Workers of America, and is published at Fernie, Crow's Nest Pass, British Columbia, on October 28th printed the following statement, which it said is "a copy of the understanding of the situation upon which negotiations would be resumed" between the Western Coal Operators' Association and the official representatives of District No. 18, U. M. W. of A. This statement was "given in the letter signed by Hon. Robert Rogers, Minister of the Interior for Canada," and acknowledged as correct by five officials representing the U. M. W. of A. and Messrs. Lewis Stockett and O. E. S. Whiteside, representing the Western Coal Operators' Association. The statement follows:

"In reference to the various interviews I have had with your committee regarding the settlement of the dispute existing in the coalfields of Eastern British Columbia and Alberta, my understanding of the basis of agreement arrived at is as follows:

"That an agreement is to be drawn up, taking the Gordon award of the Board of Conciliation as a basis.

"In this it is understood that an open-shop is conceded to the operators and a non-discrimination clause inserted in the same similar to the one now on file with the Department of Labour at Ottawa.

"That a uniform day wage scale of wages shall apply, applicable to all mines in the Association; said scale to be the scale of the Western Coal Operators' Association of the last agreement with the increased percentage by Dr. Gordon added.

"Contract rates to be the same as provided in the last agreement with the following exceptions:

"1. An increase of three per cent. in contract rates at Lethbridge.

"2. A differential of five cents to seven cents per ton on all pillars presently without a preferential, the application to be made by mutual consent.

"3. An adjustment of the contract rates at Lille mines so as to make the rate proportionate to the thickness of the seams.

"The operators agree to make deductions from union members' wages for union dues for such amounts

as they have given definite orders from the individuals, with specified sum as limit of deduction.

"The management of the mines is to be fully vested in the various companies.

"All employees connected with the management of the mines are not to be under the jurisdiction of the union or members thereof.

"The term of the agreement to be for three and a half years, expiring March 31, 1915."

In the matter of the settling of the prices on new work, which were not determined at the expiration of the last agreement, and of the differential on pillars which was to be determined by mutual consent, it is understood that the committee for each side appointed to complete this agreement determine these prices at once. If they fail to agree, an independent chairman shall be called in to do so. If the committee fail to agree on a chairman, the Minister of the Interior shall be asked to appoint one immediately

The District Ledger added the following comme

"Messrs W. B. Powell, president; C. Stubbs, vi president; and A J. Carter, secretary-treasurer, members of the executive of the Mine Workers, n the Operators to-day for the purpose of discussing tails of the proposed agreement.

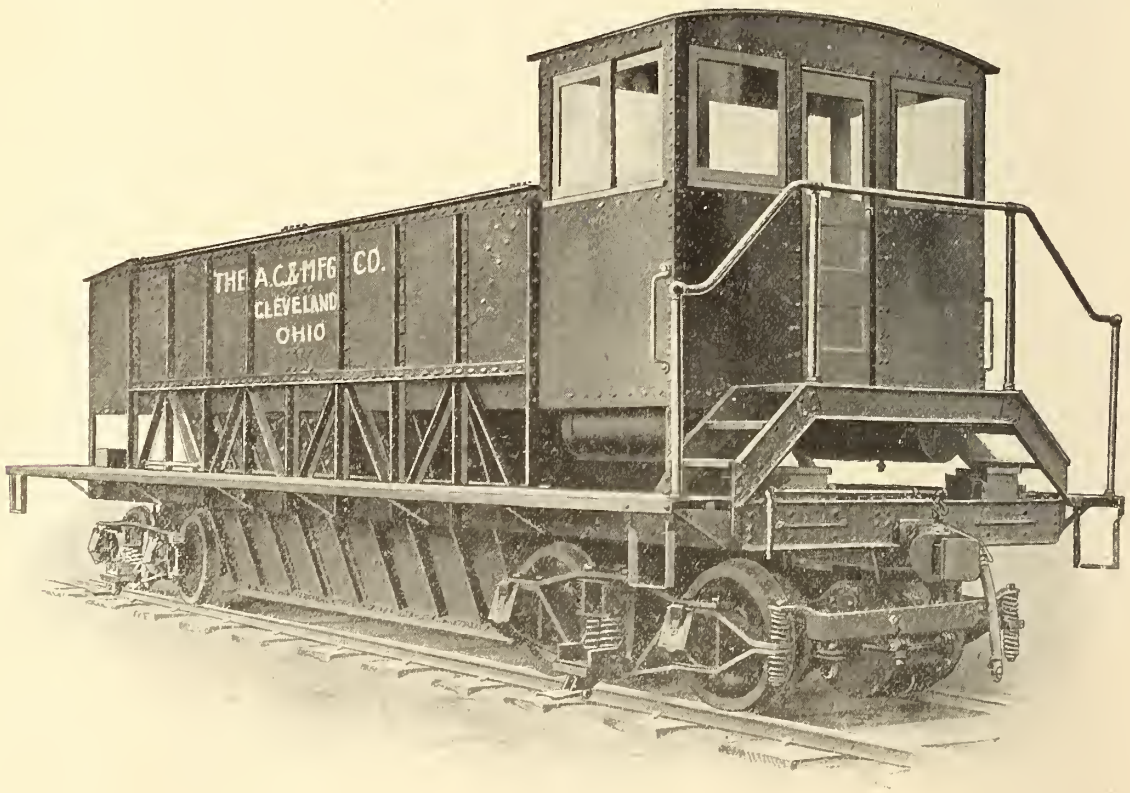
"As there are many matters of detail to be cons ered, these will occupy the attention of the parties terested so that they may be drafted out clearly f presentation to the members of the organization whom they must be submitted so that a referend vote may be taken.

"We may add that it is understood that the m will be given the same working places as they h prior to April 1, provided, of course, that applicati is made within a time to be specified later."

Industrial Section

A NEW TYPE OF ORE TRANSFER CAR.

A number of new features in construction and electrical equipment have been brought out in an ore transfer car being built by the Atlas Car & Mfg. Co., Cleveland, Ohio. This car was originally designed for handling zinc ore; it is, however, adapted to any other ores.



The car is rigidly constructed. Box girders support the body, and the sides of the car act as trusses to transfer the weight of the contents to the body bolster. The trucks are of the arch-bar type and are of a very heavy design. Four doors in the bottom of the car are operated in sets of two each by compressed air and easily discharge the load. As the weight of t contents has a tendency to force the doors open aft the toggle keeping them closed is released, only small amount of air is required for this purpose. T tight joint which eliminates the loss of fine ores made possible by the design of the doors, and wh closed they are positively locked. A stationary apr running under the car on either side, prevents th scattering of the load, so that the contents are dumpe between the rails, eliminating loss.

A cab is placed on each end of the car. The opera or's cab is at the forward end, and here are locate in convenient positions the air valves, master co

roller, and minor operating equipment. The auxiliary cab at the rear end contains a contactor controller, resistances, series relay, main line switches, etc.

The power for propelling the car is taken from third rail shoes attached to the trucks. Two 220-volt series relay type motors, which are spring-suspended, propel the car. The motors are rated at 53 h.p., based on a 75 degree centigrade temperature rise in one hour over the normal temperature of 25 degrees.

The controlling device is an important feature of the car. It consists of the various switches and relays, which are mounted on slate panels and assembled on a switchboard having an angle iron frame and sheet iron covers, which entirely enclose the apparatus. This equipment enables both motors to be operated, either in series or in multiple, in either direction, all the changes being secured magnetically. The control equipment includes a double pole main line service switch, two double pole magnetic switches for reversing the motors from series to parallel operation, individual auxiliary switches, cast grid resistance, a drum type master controller, and an overhead coil or current limiting relay. This coil protects the motors and is so constructed that when it operates the motors are disconnected from the line. It is reset automatically by bringing the master controller to the opposite position. The equipment provides seven speeds in either direction. Four of those are with the motors arranged in series and three with the motors in multiple. All of these speed variations are controlled by the operator, but if he so desires the master controller can be thrown to the full series position and the motors will be automatically accelerated by a series relay which limits the current employed to a safe amount. This arrangement can either be used for changing from full series to full parallel operation.

Principal dimensions and specifications of the car are as follows: length over all, 36 feet; width over all, 11 feet six inches; height from rail to top of cab, 13 feet; height from rail to top of body, 10 feet; capacity, 100,000 lbs.; capacity, 800 cubic feet; diameter of wheels, 33 inches; gauge of track, 56½ inches; weight of car, 63,000 lbs.

The equipment of the car includes an air compressor, an air brake and a pneumatic sanding device. Rolled steel wheels are used and a running board is provided on either side of car.

The Michigan copper ores as mined in the year 1910 average 1.025 per cent. copper.

The average lead and zinc tenor of Missouri ores in 1910 was 2.3 per cent.

Silicon bronze, in which silicon replaces phosphorus, is stronger and more ductile than phosphor bronze and does not rust.

The output of the Nova Scotia Steel and Coal Company for October was higher than ever before. 52,675 tons of iron ore were mined; 75,521 tons of coal; 7,253 tons of pig iron made; 6,456 tons of steel billets; and 4,718 tons of bars and plates. The October shipments of finished steel and forgings were 5,500 tons, as compared with 4,909 tons during September.

To ensure the complete combustion of petroleum, it is necessary that it be either sprayed or gasified. Most oils used for fuel are heavy and viscous. At higher temperatures the viscosity disappears. This makes it good practice to pre-heat the oil, using exhaust steam for the purpose.

Lithophone is a very white pigment precipitated by the double decomposition of zinc sulphate and barium sulphide. An intimate admixture of the two decomposition products is formed. Barium sulphate and zinc sulphide are the mixed products. 70 and 25 per cent. are the relative proportions of the two.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Purchase of Timber Limits by the Dominion Steel Corporation.

It is announced that the Dominion Steel Corporation has purchased the Montgomery timber areas near Dalhousie, N.B. These areas, together with extensive holdings in Newfoundland, and the very valuable lumber properties taken over by the Steel Corporation from the Cumberland Coal and Railway Company, will make the Corporation a considerable factor in the maritime lumber industry. The quantity of lumber needed in the operation of the steel works and particularly the collieries, is nothing less than immense, and the management of the Corporation has done a wise thing in tackling what bids fair to become one of the most pressing problems of the allied industries. The cost of pit-timber is an annually increasing charge, and as the demand enlarges there will be an actual scarcity with present methods of lumbering. There is no necessity for this condition to arise, however, as the vast uncleared lands of Cape Breton and Nova Scotia would yield an indefinite supply of suitable pit timber if proper methods of forestry are in the future adopted.

Eight Hours' Act in England.

When the question of an eight hour day in the mines of Nova Scotia was being pressed, your correspondent ventured to affirm that it would be just as well to see how the eight hour day worked out in practice in the English mines before enacting similar legislation in Nova Scotia, and the course of events has proved that the position then taken was a proper one. Nothing in recent legislation connected with coal mining has caused so much trouble as the Eight Hour Act in Great Britain. In the Midlands Coalfield of England, the triple shift and eight hour day has been in operation for many years, and almost all the mines there are designed to be worked in this way. In this district naturally the Act has not made any appreciable difference. In the north country, however, it has caused infinite trouble, and there is more to come. In many respects the conditions under which coal has been mined for generations in Durham and Northumberland resemble those attending coal mining in Nova Scotia. This is partly due to the fact that coal mining in Nova Scotia under the General Mining Association was largely directed by men who came from the north country, and it is interesting to-day to notice the great similarity between the mining terms used in Northumberland and in Nova Scotia. Again, the market of the north country is for sea-borne coal, and it is affected by the season of open navigation in the Baltic, as the Nova Scotian market is affected by the state of navigation in the St. Law-

rence River. In the north country they have worked for generations on the two-shift system, and they take very unkindly to the domestic upset which the triple-shift system necessitates. For many years the north country miners remained obdurate and would not agree in the efforts made by the Miners' Federation to bring about a general compulsory eight hour day in mines. Recently, however, the opiuions of the miners of the Midlands have gained the ascendancy over those of the Durham and Northumberland men, aud they reluctantly acquiesced in the eight hour legislation. The Miuers' Federation, it is understood, intends to stand behiud the demand of the Northumberland men for a return to the two-shift system, while, on the other hand, Sir Christopher Furness has stated at a shareholders' meeting that his company will close their collieries rather than revert to the two-shift system under a compulsory eight hour day. The conditions which have made the eight hour day such a failure in the north country in England are even mcre acute in Nova Scotia, and coming events in England will prove with even greater certainty than at presetit that the Magill Commission was perfectly correct when it reported that the adoption of a compulsory Eight Hour Act in Nova Scetia would be disastrous to the coal industry of the provinec.

One of the chief factors in the present unrest amongst English miners is the reduction in their earnings which has been directly caused by the Eight Hours Act; and the threatened strike, if it comes about, will be an endeavour to get the same wages for eight hours that were formerly earned in nine or ten hours.

Renewal of the P. W. A. Agreement.

The P. W. A. has accepted the Dominion Coal Company's offer of a renewal of the Two Years' Agreement on the same terms and conditions as formerly, and the term of the agreement has been extended until the end of 1913. The first long-term wage agreement betweeu the Coal Company and the P. W. A. was made in 1904 for a term of three years. At the end of this period a Conciliation Board was asked for by the P. W. A., and sittings were held under the benign chairmanship of Professor Shortt, a gentleman whose able and conciliatory guidance is still remembered in Glace Bay. On the result of the Shortt Board's award a two years' agreement was entered into betweeu the compauy and the P. W. A., which expired at the end of 1909. This was renewed at the end of 1909 for a further period of two years, and, as just mentioned, has once more been renewed. The various agreements, therefore, cover a space of nine years.

The local leaders of the U. M. W. have announced their intention to protest against the renewal of the agreement, and are once more endeavouring to create dissatisfaction. The net result of the recent U. M. W. strikes was the utter impoverishment of the strikers, strangely accompanied by a noticeable increase in the worldly goods of the salaried leaders, and it is suspected that the present activity of these same gentlemen is actuated more by the desire to make their own calling and election sure, than by solicitude for the welfare of those they aspire to lead.

Dominion Coal Outputs.

The individual outputs of the Glace Bay collieries during October were as follows:

No. 1	50,120
No. 2	63,110
No. 3	12,650
No. 4	35,590
No. 5	25,550
No. 6	22,460
No. 7	17,600
No. 8	14,610
No. 9	35,680
No. 10	16,270
No. 12	26,970
No. 14	20,220
No. 15	5,580
No. 16	1,990
No. 21	1,600
Tons	350,000

This tonnage has been exceeded only once in the month o October, namely, in 1906. The total output for the year to th end of October amounts to 3,323,791 tons, compared with 2 938,085 tons at the same date last year.

The shipments were fairly high, amounting to 365,000 ton The St. Lawrence season is almest over, and it is expected t reach 1½ million tons, the largest shipment yet attained by th Coal Company during the season of open navigation. Th coal banks are all lifted in good time, and geuerally the sea son has been a good one. Both in outputs and shipments new series of records has been established.

The Springhill output for October was 36,060 tons. Th output steadily increases, and will continue to do so durin the wiuter. An air-compressor is being installed, and it is in tended to operate a number of shearing machines. Up to th present time no machine-cut coal has been mined at Spring hill. By shearing or "nicking" the coal in certain places larger and stronger coal will be produced. No explosive i used in getting dowu the coal at Springhill. So far as it analysis and calorific value is coucerned, the Springhill coa leaves little to be desired, but it is a friable coal which pro duces a great deal of slack in the mining. This slack with suitable binder would make an ideal briquette, and it woul not be surprising to know that a plaut of this kind was in con templation.

ONTARIO.

Cobalt and Elk Lake.

While the shipments from the camp iu the box car ar gradually decreasing, the consignments of bullion by expres creep up and up. Next year there will be very little low grad ore, indeed, sent out at all from the camp, it being the inten tion to treat it on the spot. The Nipissing has found the re duction of its high grade ore to bullion so profitable that Mr Chas Butters is now working to discover a process that wil recover the values in the low grade ore with economy.

The Drummond has experienced a second birth. During th year Mr. E. V. Neelands, who is now in charge, in addi tion to the low grade ore that he has been shipping from th old workings, has sent out $40,000 in high grade ore. He has also discovered on the surface by prospecting, several excellent new veins, which will be crosscut for this winter. There is a very considerable amount of life in the Drummond yet.

The Temiskaming and Hudson Bay Mining Company has de clared the 35th dividend of 300 per cent. The company has now paid 19,000 per cent., or a total of $1,474,590. Mr. Horace T. Young has resigned the management of the property and Mr. A. H. Brown, who has directed the development of the Pike Lake claims at Swastika for the past six months, takes his place.

The City of Cobalt Mining Company has taken a lease of the King Edward mill, which has been shut down now for about a year. The capacity of the mill is 50 tons per day. From the City of Cobalt to the King Edward, at Cross Lake, there is a haul of a mile to a mile and a half. Since the contract with the Northern Customs mill expired the City has been obliged to leave the low grade ore on the dumps, where a considerable tonnage has already accumulated.

The mill report of the Buffalo Mines for the month of September showed that over 100,000 ounces had been recovered from 32.95 ounce ore. The report reads: mill ran 561 hours; ore milled, 3,732 tons; average assay, 32.95 ounces; ounces re-

covered, 102,336; mill expenses, $11,466; ounces paid for, 105,988.

A good discovery of silver is reported from the Donaldson claims at Elk Lake. A shaft was sunk on a two-inch vein of calcite which is reported to have widened considerably and to have more than maintained its surface values.

After many rumours, found to be groundless, the Hitchcock, at Elk Lake, is at last reported to have despatched ten tons of ore to the smelter. Some of the ore will run high in silver, but the shipment, taken as a whole, is low grade.

R. B. Stewart, for the Ontario Bureau of Mines, has made a report to the Government on the Shining Tree gold discoveries. The report is non-committal, the geologist being of the opinion that not enough work had been done to warrant any definite statement.

The Casey Cobalt mine, in Casey Township, north of New Liskeard, has made a shipment of 20 tons of high grade ore and 23 tons of low grade.

The Green Meehan has also shipped some concentrates.

After a long and animated sitting, the La Rose decided not to declare an extra disbursement in addition to the usual 3 per cent. A number of the directors wished to reward shareholders with some of the big cash surplus, but the majority were in favour of maintaining the present large reserve until it is seen what is the outcome of the extensive exploration scheme in search of new bodies on the Lawson and the La Rose proper. At the La Rose proper the winze is being put down to the 400-foot level, from which point very extensive exploration work will be undertaken.

The position of the La Rose on October 20th was: cash in bank and ore at smelter, $1,401,668; ore ready for shipment, $91,182; total surplus, $1,492,849.

The financial standing of the Nipissing on October 20th was: cash in bank, $999,894.59; ore in transit and at smelter, $131,782.94; ore ready for shipment, $197,653,; total, $1,329,330.53.

The Beaver has now reached the 460-foot level, and a station in the main shaft has been cut at that level. The foundations for the new mill are completed and every attempt will be made to rush forward the work.

The McKinley-Darragh is now producing at the rate of 250,000 ounces per month, and will at the end of the year have shipped or despatched to the smelters 2,500,000 ounces. The output would have been considerably larger if the lack of power at the beginning of the year had not handicapped work.

Porcupine and Swastika.

The first fall of snow has come in Porcupine, and frost has stiffened the ground so that all surface work and prospecting will soon have to be abandoned. The last two months of surface exploration has yielded generously in new finds. From this time forward till next spring the main activity will be in the erection of buildings and underground development. The mines losing their camps in the big fire are completing their permanent buildings and getting out of the tents in which they have been obliged to work all summer. Thanks mainly to the spur it ran into its property, the construction work on the Dome plant has progressed very favourably, and the forty stamps should be dropping soon after the new year comes in. At the Hollinger there has been no attempt to get any mine machinery into the camp, but the construction of new buildings has made great headway. The office, the assay house, and the bunk house are completed, while the manager's house, the mine captain's house, and the club house are well under construction. The foundations of the mill have been laid and the walls are now going up. The slide of 400 feet of grade into Pearl Lake from the T. & N. O. will not permit the completion of the line into the Timmins Townsite at the earliest before January, but the railroad company is going to provide a siding near the McIntyre, from which point the Timmins and other adjoining companies can team their supplies over the winter roads.

The Northern Ontario Light & Power Company has taken over the assets of the old telephone company, and will instal a new system as quickly as possible. There is a keen competition developing all over the camp between the British Canadian Power Company and the Northern Ontario Light & Power Company, and rates should be light. The Northern Ontario Light & Power Company is now connected with the Porcupine Power at Sandy Falls, on the Mattagami River, and they are lighting both towns, but have not an exclusive franchise. The British Canadian is rushing in machinery as fast as the roads will permit, to Waiwaitan Falls, where they are developing power. It will be ready to give service some time next year.

The sensation of the month followed the announcement of Col. Weatherley, an Alaskan operator, that he had made a wonderful find on the Brydge claim next to the Preston East Dome, and now known as the Little Pet mine. On the surface the discovery consisted of a number of stringers of quartz, rich in coarse gold, running through a big porphyry dike. Two shafts have been put down on them. The No. 1 shows that the quartz stringers have widened out into two seams of quartz from 6 to 17 inches wide, very spectacular. In the other shaft the vein has widened very materially also, and is now about five feet of quartz and schist, the quartz carrying much coarse gold. The owners took a sample of the quartz porphyry and obtained an assay of $11 per ton from it. The visible gold appears to be contained exclusively in the quartz stringers and in the seams of the porphyry.

Mr. Chas. D. Taylor is reported to have bought the controlling interest in the Porcupine Imperial Mining Company in Deloro. The Dome Mining Company was at one time in negotiation for the property, but the deal did not go through.

Mr. Burr Cartwright and his associates have thrown up the option on the Brydge McAuley claims in Bristol township after doing a considerable amount of work and making several small payments. The price under the option was for $500,000, but payments were spread over two years and were for the first two or three months very small. The Dome Mining Company will also abandon its lease on the Josey Woods claims in the Cripple Creek district in a few days. The full price here was $250,000, but initial instalments were quite small. The shaft was sunk to 50 feet, where the vein split. These two failures to proceed with work on the two most important properties west of Pearl Lake will delay development of this part of the country.

The Dome officials paid a hurried visit to the property at the end of last month. They wished to see over the property before the snow hid the surface discoveries. Mr. Ambrose Monell, general manager of the Dome Mining Company, stated that the results of the diamond drill work had been most satisfactory as proving that there was good ore over a wide area and for a considerable depth. Values in the cores varied so greatly that it was as yet impossible to strike an average, but it was much better than they expected. So far underground operations had shown that the ore ran on an average higher than the assays from the cores would lead to believe. The mill is rising fast, nearly all the brick finished buildings are completed, and by the first of the month the Dome will completely have recovered from the fire and will be in a position to turn out gold bricks.

Mr. Frank Armstrong and a party of friends have been inspecting the camp during the first week in November. Mr. Armstrong is directly interested in the Dobie and the Plenaurum, and more time was spent at these properties than anywhere else. Some remarkably spectacular ore has been taken off the Deloro claims of the Dobie Mining Company, and during the winter months very active operations will be carried

on there. Two shafts will be sunk a thousand feet apart to prove up the length and depth of the ore body.

J. T. R. Laurendeau, a director of the Crown Reserve, has purchased the controlling interest in the Hughes Porcupine gold mine. Mr. Mowery Bates has been appointed manager and he has already commenced to sink a shaft on the vein and put up camp buildings for a big force of men. The Hughes has one of the most remarkable surface showings in the Township of Whitney, but so far little beyond assessment work has been done on it.

At a meeting of the Foley-O'Brian Mining Company, the treasurer reported that there was cash in hand, $144,930 available for development purposes. It was stated that at 140 feet a number of small veins in the schist ran $12 to the ton over a width of 18 feet.

It is extremely likely that C. H. Poirier, manager of the Vipond property, will be offered and will accept the position of consulting engineer to the Rea Consolidated mines. He will still retain his position at the Vipond if he does obtain the Rea.

In the first week of November the main vein of the Rea was cut at the 300-foot level, 35 feet from the shaft. At this point it was 30 feet wide, of almost solid quartz. While the vein pans gold it does not show any free gold. No representative assay had been taken at the time of writing. It is very probable that the Rea will shortly commence the erection of a ten or twenty-stamp mill.

SOUTHERN ALBERTA.

The following notes were obtained about the middle of October. As it was reported late in that month that a basis of agreement had been reached between the Western Coal Operators' Association and the officers of District 18, United Mine Workers of America, representing the employees, it is possible that before these notes shall be published work will have been resumed at the various coal mines and coke ovens at which it was suspended at the close of last March.

Galt Collieries.—Work at the Alberta Railway and Irrigation Company's Galt coal mines is still restricted to keeping the pumps going at both Nos. 3 and 6 mines, and making additions and other improvements to the surface plant at the latter. A third 500 h.p. unit of Babcock & Wilcox water-tube boilers is being put in. Other additions to plant being prepared for are a third compressor, 200 k.w. generator, and another Webster 1,000 h.p. vacuum feed water heater.

Diamond Coal Company.—While miners are on strike, plant and machinery is being thoroughly overhauled and put in condition for active operations immediately after settlement of labour troubles.

Chinook Coal Company.—Much progress has been made with work of putting in surface plant and equipment. The tipple is completed; it is a steel structure with modern coal-handling machinery, and screening and picking appliances. Erection of masonry boiler and power-houses is finished, and machinery is being placed in position. Underground development is also being energetically proceeded with.

Lethbridge Collieries, Limited.—This company's colliery is situated about 7 miles from Lethbridge. During the last 12 months two shafts have been put down 600 feet to the coal, and openings made therefrom preparatory to mining the coal. A steel tipple building, with rotary tipple, has been erected by the Wisconsin Bridge and Iron Company; the tipple has been equipped with screening and other machinery by the Link Belt Company. Large boiler, power, and other brick buildings have been erected, and much plant and machinery put in. The boiler equipment consists of two 500 h.p. batteries of Babcock & Wilcox water tube boilers with chain grate stokers, induced draft fans, etc. In the power and hoist-houses are large compressor, generator, powerful hoisting engine, and much other machinery. The whole constitutes a complete and thoroughly modern bankhead equipment, designed by Mr. Charles Fergie, of Montreal, and erected under the supervision of Mr. N. C. Pitcher, resident construction engineer. About 300 men are employed, some in doing underground development work and others on surface improvements. Mr. Wm. Maxwell is superintendent.

Leitch Collieries, Ltd.—This company's south mine, at Passburg, is still being worked, but with fewer men than in the past. Operations at its north mine, near Police Flats, are now having most attention. Owing to the labour troubles, affecting the whole district, only about 100 men are employed which is but one-third of the number that will be required to operate mine and coke ovens at full capacity. Erection of 10[illegible] rectangular coke ovens, Mitchell type, has been completed; also of a 1,500-ton per day Roberts & Schaefer Company tipple and a Luhrig jig washery .

Davenport Coal Company—This company's mine is at Burmis, on the Crow's Nest Railway. Its output capacity under ordinary conditions varies up to 450 tons per day, with 90 men employed, but this production is not being maintained at present, for the mine is being operated with less than a full working force of men. Six seams occur on the property, but coal is being mined from two of the six seams prospected on the property; the average thickness of the coal is 10 feet.

Breckenridge & Lund Company.—This company's mine is at Lundbreck; its normal output ranges up to 400 tons of coal per day with 80 men employed. Coal is being mined from two of the six seams prospected on the property; the average thickness of the coal is 10 feet.

Canadian Coal Consolidated.—This company (formerly the Canadian-American Coal & Coke Company, Ltd.) owns coal lands at Frank. The old company was the first to mine coal in this district. Pending settlement of the coal miners' strike, coal is being mined for market, but production will be resumed as soon as shall be practicable after existing difficulties with the employees shall have been adjusted.

West Canadian Collieries, Ltd.—Large holdings of coal lands in Blairmore-Frank district are possessed by this company, the chief share interest in which is held in France. Ordinarily the company operates three collieries, namely, those known as Lille, Bellevne, and Blairmore, respectively, but only the last-mentioned is now producing, with non-union men employed.

International Coal and Coke Company.—The mines and coke ovens of this company are near Coleman. At present only necessary upkeep work is being done, but production will be resumed as soon as this shall be possible.

McGillivray Creek Coal and Coke Co.—Ordinarily output from this company's mine, situated at Carbondale, one mile west of Coleman, is 400 to 500 tons of coal per day, but work is suspended at present. When the driving of a rock tunnel shall be completed, output capacity will be substantially increased. Surface plant includes a modern steel tipple with a capacity of 2,500 tons per day; it is equipped with a F. C. Greene dump, and produces slack, run-of-mine, and lump coal. At Ottumwa box car loader has just been put in.

Other District Mines.—Other coal mines in what is officially known as the Crow's Nest district are those of the Hillcrest, Maple Leaf, and Galbraith companies, respectively. About Lethbridge, the Pioneer (Ashcroft), and New Barnes, two small mines, are together supplying about 100 tons of domestic coal per day to Lethbridge consumers, while the Royal Collieries, Ltd., also near Lethbridge, has its mine idle through the miners' strike.

In South Fork District.—Several development companies have been prospectin coal lands situated in the vicinity of the south fork of Old Man River. Of these, the operations of the Head Syndicate, Limited, an outline of whose property and work was published in the Canadian Mining Journal of September 1, are the most important. Two adits

have been driven on the coal from near the company's camp on Lynx Creek. A crosscut adit, designed to cut the several seams, was commenced last July; after passing through 280 feet of mostly hard rock a large seam of coal was entered on October 21. When visited on the following day 12 feet of coal had been cut without the farther wall having been reached. It was expected this seam would be proved to be 15 feet in thickness, all good coal.

BRITISH COLUMBIA.

Slocan.—A new company, known as the Slocan Star Mines, Limited, has been organized to acquire two groups of mineral claims—the Rabbit Paw and Slocan Star groups, respectively—situated near Sandon, Slocan mining division, together with the Slocan Star concentrating mill, water rights, etc. Briefly, the Slocan Star, Silversmith, and Heber fraction claims have been developed to a depth of 600 feet. The present workings consist of six levels, with various intermediates. Generally speaking, the high grade ore has been nearly all extracted down to the fifth level, so far as the Slocan Star vein is concerned. There are, however, numbers of places where ore mixed with gangue has been left standing, and this should yield a profit if dealt with in conjunction with ore of higher grade from other orebodies, if such shall be developed. The company's consulting engineer has recommended that an adit of 430 feet vertically and 600 feet on the incline, below the present fifth level. The most of this development work is estimated at about $40,000. It is understood that the engineer's recommendation has been adopted and that the work will be commenced shortly.

Sheep Creek.—The Mother Lode Sheep Creek Mining Company, a State of Maine incorporation, the principal stockholder in which is Mr. John McMartin, of Cornwall, Ontario, is making progress with the erection and equipment of its 10-stamp mill, in Sheep Creek camp, Nelson mining division. In designing and equipping this mill, the aim of the management has been to make it one of the best gold mills in the world, and it is confidently expected by those chiefly interested that this object will be attained, for the best talent available has been employed in connection with both design and equipment, and this after adequate experimentation with ore from the Mother Lode mine, to determine the most effective method of treatment so as to secure the highest results practicable. Erection of the mill building was commenced last June; it is now being roofed, and machinery and plant is being put in place. The expectation is that a commencement to crush ore will be made by the end of the current year. It is thought a crushing capacity of 70 tons per day, with ten stamps dropping, will be developed after the machinery shall be in good running order. In designing the building and plant, provision has been made to allow of doubling the treatment capacity of the mill at comparatively small expense, whenever conditions shall make this advisable. The Mother Lode mine has been developed to a depth of 500 feet below the outcrop of its main vein, and it is estimated that there is sufficient gold ore blocked out to keep the mill supplied continuously for three years.

Rossland.—From the recently published sixth annual report of the directors of the Consolidated Mining & Smelting Company of Canada, Limited, it is ascertained that during its last fiscal year the production of the company's Centre Star group of mines, in Rossland camp, was 193,223 tons of ore, which contained 81,348 ounces of gold, 60,200 ounces of silver, and 2,318,456 pounds of copper, together having a gross value of $1,980,112. The general average metal contents of the whole of the ore produced during that year, as above, were as follows: Gold, 0.421 ounces, and silver, 0.312 ounces per ton, and copper 0.6 per cent. The average gross value per ton was a fraction under $10.25. The footage of narrow work done during the period under review in those mines was as follows: Drifting and crosscutting, 11,298.5 feet; raising, 1,803 feet; sinking, 290 feet; total, 13,383.5 feet. There was also 25,622.3 feet of diamond drilling done. The managing director's comment was: "In our Rossland mines ore developed and shipments have about balanced. Although the tonnage developed is numerically less than for the previous year—194,000 tons as against 245,000 tons for the year 1910—the average value of the ore developed this year on the lower level is considerably higher. In the Centre Star and Idaho mines no ore has been developed in the lower levels and but little work done, most of the development having been confined to levels above the 10th. In these a number of small orebodies have been opened, and one or two larger ones of lower grade. The same is true of the Iron Mask. The greater part of the new ore that has been found has been in the lower levels of the War Eagle. A winze sunk from the 12th level opened ore to a depth of 150 feet and of a length at the bottom of 200 feet. The value of this ore is very good. The 10th and 11th levels are also producing a large tonnage of good ore." Other comment of the managing director concerning property in this camp was the following: "Since the close of our fiscal year, arrangements have been completed with the liquidator of the Le Roi Mining Company for the purchase of all the property of that company at Rossland. This property still has a large amount of low grade ore, and some prospects of finding ore of a better grade, and we believe that the purchase will be a profitable one."

Trail.—The Consolidated Mining & Smelting Company's annual report shows that during the last fiscal year 388,735 tons of ore were smelted at the Trail smeltery. The valuable metal contents of this ore were: Gold, 119,067 ounces; Silver, 1,458,758 ounces; lead, 24,026,015 pounds; copper, 4,421,988 pounds. The gross value of these metals was $4,437,901.

During the month of September of the current year the Consolidated Company received 24,713 tons of ore, and smelted 24,713 tons. The total gross output for the month was valued at about $593,000; of this total value, 67 per cent. was in gold. The total gross output for the quarter ended September 30th, was $1,460,000, and the proportion of gold in this total value was about 63 per cent.

The aggregate tonnage of ore treated at Trail during all years to June 30th last is 2,847,469 tons, and the aggregate gross value of the metals recovered $47,083,926. The total quantities of the several metals were: Gold, 1,017,123 ounces; silver, 13,458,631 ounces; lead, 224,898,570 pounds; copper, 47,875,802 pounds.

Boundary.—The British Columbia Copper Company has continued operating its mines and smeltery without intermission, notwithstanding the long continuance of the strike of the coal miners and coke oven workers in the Crow's Nest district, whence it had long obtained its supply of coke for metallurgical purposes. The largest proportion of the ore required to keep its three blast furnaces supplied has been obtained from the company's Mother Lode mine, while a much smaller quantity, of oxidized ore, came from its Wellington group mine. The Rawhide and Athelstan, both owned by the New Dominion Copper Company, controlled by the B. C. Copper Company, supplied the greater part of the remainder of the ore smelted, the former in large and the latter in small degree. Pennsylvania coke has been used at the company's smeltery at Greenwood, ever since the supply from the Crow's Nest district was cut off.

The B. C. Copper Company has relinquished its bond on the McKinley mine, in Franklin camp, north fork of Kettle River, and ceased work thereat. Two neighboring mineral claims were afterwards taken under option of purchase, and these have since been under development, but work was lately suspended for the winter, under arrangement to resume operations next

With the promise of an early settlement of the coal miners' strike has come assurance that the Granby Company will re-

sume mining and smelting ore as soon as sufficient coke shall have been received to admit of the furnaces being kept in blast. During the summer preparations have been made for a new system of disposal of slag, by water granulation and conveyance thereafter by means of a system of belts to a sufficient elevation to allow of a new dump being thereby secured. Only two of the eight furnaces have as yet been connected by flumes with the new system, and if it shall be found that this works well the remaining six will be similarly provided with facilities for slag granulation and the present method of hauling molten slag in large pots by steam locomotives be done away with altogether. All arrangements for crushing ore at No. 3 tunnel outlet from the mines at Phoenix and loading direct into railway cars have been completed. These take the place of crushing and shipping facilities destroyed or rendered useless by fire last year.

GENERAL MINING NEWS.

NOVA SCOTIA.

Halifax.—The Nictaux, Annapolis Co., iron ore concentrating mill, in course of erection for the Canada Iron Corporation, will soon be ready to be placed in working order. The low grade magnetites and the higher grade red hematites will be jigged and brought up to about 57 per cent. iron content. The product will be commercially free from sulphur.

ONTARIO.

Cobalt.—After building up a surplus of over $1,300,000, La Rose is now proceeding to spend considerable money in exploration work for new ore bodies. La Rose found its main vein at 200 feet, but it did not contain values. In his recent work in Cobalt camp, Prof. Miller figured there was one main fissure vein down the centre of Cobalt.

From this vein McKinley-Darragh is still producing. Right of Way paid all its dividends, and La Rose mined millions. Government geologists figure there has been a throw of 400 feet, and La Rose to-day is sinking to the 400-ft. level to endeavour to pick up values again. In the meantime, good ore is being produced from subsidiary veins on La Rose property. Lawson is producing about 50,000 ounces a month, and Princess 40,000.

Cobalt, Ont.—The mill report from the Buffalo Mines for the month of September shows a record treatment for the year of ore milled.

During the month in the 561½ hours that the mill was running, a total of 3,732 tons were treated in the concentrator and cyanide plant of the property. The general average monthly treatment of the property is around 3,200 tons, so that the September treatment is a record in its line.

The average grade of ore is slightly lower than last month, being 32.95 ounces to the ton, as compared with 34.49 ounces for the preceding month. A total of 102,336 ounces were recovered by the process of concentration, the largest amount in three months.

The report for the month, as compared to the August report, is as follows:

September—Mill ran 561½ hours; ore milled, 3,732 tons; average assay, 32.95 ounces; ounces recovered, 102,336; mill expenses, $11,466.11; ounces paid for, 105,988.68.

August—Mill ran 592½ hours; ore milled, 3,093½ tons; average assay, 34.49 ounces; mill expenses, $9,439.76; ounces paid for, $144,446.06.

The last dividend paid by the Buffalo was October 2nd, and was for 5 per cent.

Cobalt.—The Casey-Cobalt Mines, whose property lies in the centre of one of the best agricultural belts in the Dominion of Canada, just north of New Liskeard, has just made two shipments of ore, the third during the present year.

The recent shipment included 40,415 pounds of high grade ore and 46,224 pounds of low grade material.

The high grade ore was sent to the Delore smelter at Marmora and when the final assays are received the mine expects that the car will run better than 3,500 ounces to the ton, or nearly 70,000 in the car. The low grade was screenings sent to Denver. It will run in the neighbourhood of 400 to 500 ounces.

Cobalt, Nov. 5.—Within the past week there has been a general improvement in the position of La Rose Consolidated. At Lawson crosscut, half way up the stope from the 180-foot level on vein 8, what appears to be another ore shoot has been encountered to the west. It will average some thousands of ounces, six inches wide, and, after being drifted on for 15 feet, is as good as ever in the head of the drift. The Lawson has never this year produced less than $40,000 per month, and is likely to produce much more now.

At the Princess a new vein two inches wide, of 6,000 ounces of ore, has been crosscut 30 feet up in the slope from the 135-foot level, and has also been encountered on the level itself, so that it holds for some distance.

At Fisher Eplett, where previously nothing had been found, a foot-wide vein of quartz and calcite has been uncovered for 50 feet. In it occurs two patches of high grade silver, a foot long by a couple of inches wide. The vein will be sunk on at once.

Cobalt, Nov. 2.—Mr. R. B. Watson has made another unexpected strike on vein No. 8 on the Lawson property. The strike promises to pan out uncommonly well and gives every indication of producing a great deal of high value ore.

A strike almost equally good has been made on the Princess property.

Toronto. Nov. 2.—The City of Cobalt Mining Company has taken a lease of the King Edward concentrator on Cross Lake, and will treat its low grade ore at this point in future, teaming it from property to mill. King Edward mill was built three years ago by the mining company, but last winter it was decided to close operations at the time for an indefinite period and the mill has been lying idle ever since.

Matheson, Nov. 7.—Two gold bricks of 50 ounces left Matheson yesterday from the American Eagle mine, in Munro Township. These bricks represent $2,000. Within the past two months the Gold Pyramid has sent out seventy ounces, so that this season the properties in Munro and Beattie, to the east of here, have produced 170 ounces, or approximately $3,400 in gold. Both properties have been working some years.

MANITOBA.

Winnipeg.—General satisfaction prevailed throughout the west when the news of the settlement of the coal strike was published. An indefinite coal famine would have ensued if the settlement had not been so timely. Now that the mines are again in operation the danger of a fuel famine is averted, this affecting both producer and consumer to a very great extent. It will also have the effect of keeping the price of coal down to normal.

Fernie, Oct. 31.—Chief Justice Gordon Hunter is here today to preside at the fall assizes of the Assize Court. But one case is upon the docket for trial, that of A. J. Carter against

W. G. Barclay, in which the latter is charged with making damaging statements regarding Mr. Carter's action in the matter of securing relief supplies for the miners. S. S. Taylor is appearing for Mr. Barclay, and L. P. Evkstein for Mr. Carter.

The scales committee of the operators and miners are meeting at Frank to-day, to take up the arrangement of a new scale of wages in accordance with the outline laid down at Lethbridge last week, when Hon. Robert Rogers succeeded in bringing the two sides to the controversy together again after a long wait following the Macleod conference with the boards of trade convention.

The task of arranging a new scale should not be a lengthy one, since all details have been gone over so many times, and the basis arrived at being clear and well defined. If this work is accomplished within a few days, the vote upon the proposition can be taken in one day all over the district and the mines can be opened within the next week.

A few men have already gone to work at Coal Creek, cleaning up, preparatory to active operations.

Fernie, Nov. 3.—The Riot Act was read in Fernie last night by Mayor Bleasdell after a violeut outbreak on the part of the miners, when a train arrived from Coal Creek with men on board who had gone to work in the mines without waiting until the agreement now under consideration at Frank has been signed and ratified.

Large numbers of miners were on hand when the train reached here, and the men who had worked were greeted with hisses and derisive language. One man was hit upon the side of the face by a stone thrown by some one in the crowd.

Trail, Nov. 1.—During September the Consolidated Company received 24,717 tons of ore, and smelted 24,713 tons. The total gross output for the month was valued at about $593,000, of which 67 per cent. of the values were gold. The total gross output for the quarter ending September 30th, was $1,460,000, about 63 per cent. of the values being gold.

Nelson.—Supported by a group of Spokane capitalists, W. E. Zwickey, manager of the Rambler-Cariboo mine, is preparing to open up the famous Payne mine in the Slocan, a property which at one time ranked among the greatest producers in the province. Already Mr. Zwickey has a force of men at work cleaning out the tunnels and carrying on other work preparatory to operating the mine.

The Payne mine was located on September 9th, 1891, by Eli Carpenter, and Jack Seaton. They sold it to Steve Bailey for $20,000, who disposed of it after some development had been carried ou, to A. W. McCune for $125,000. Mr. McCune, it is said, took a milliou dollars' worth of ore out of the mine, and then sold it to an eastern company, from whom Mr. Zwickey has taken a bond, for $1,000,000.

The development of the mine under Mr. Zwickey's management will probably include the driving of a lower tunnel.

Rossland, B.C., Nov. 1.—The following report has been received at the Londou office of the Vau Roi Company from the manager in Rossland:

Mill Report for September.—Total amount crushed, 3.700 tons; average assay: 12.6 ounces silver, 3.6 per cent. lead, 8.9 per cent. zinc, yielding 200 tous of lead concentrates, assaying 96.8 ounces silver, 65.4 per cent. lead, and 10.1 per cent. ore, assaying 110 ounces silver, 14.7 per cent. lead, 22 per cent. zinc. Total, approximate value, $20,940. Mill ran 565 hours.

Estimated expenditure for corresponding period — Development, $2,393; ore production, $9,524; milling, $4,336; total, zinc; and 330 tons zinc concentrates, assaying 33.8 ounces silver, .9 per cent. lead, and 46.0 per cent. zinc; 6 tons picked $16,253.

Mine report for September — Shipped 260 tons of lead concentrates and 456 tons zinc concentrates. The net receipts for 280 tons lead concentrates shipped are 90 per cent. of full payment, $14,855; the net receipts for 369 tons of zinc concentrates shipped are 80 per cent. of full payment, $4,065; total, $18,920. Main vein level 5 advanced 45 feet, poor. Main level 3 advanced eastward 58 feet, of which 58 feet average 36 ounces silver, 3⅜ per cent. lead, 12½ per cent. zinc, over an average width of 2 feet 3 inches. Breast still in ore.

Nelson.—The Slocan Star Mines, Ltd., is the new company under which are consolidated the mineral properties at Sandon previously owned by the Byron N. White and John M. Harris interests, the most noted of which is the Slocan Star. The consolidation was recently affected through the efforts of Mr. Lennie, and it has permitted the operation of the important mines long locked up by litigation.

Work has now been started on No. 6, or lower tunnel, on the consolidated properties. This tunnel will tap the downward continuation of the chief ore bodies, including the one formerly in dispute, at a depth of 600 feet below the present No. 5 tunnel of the Slocan Star mine, on the dip of the vein. The work will take some time to complete, as it involves a tunnel 2,300 feet in length, but as the tunnel will pass through virgin territory it is expected that valuable veins will be uncovered. In addition to the work on this tunnel, operations will be pushed on the upper levels, and it is expected that shipments of ore from these will commence within 90 days.

UNITED STATES.

Cripple Creek, Colo., Nov. 1.—October closes as the greatest financial period in the history of the Cripple Creek district, as for the first time since the inception of the camp the dividends of the month are in excess of the gold production.

These dividends, with close corporations placed at the lowest figure and with profits of lessees not included in the total, amouut to $1,322,500 paid out by miniug companies during October, and not only break all records in Cripple Creek, but establish a new record in the state.

The output of gold ore during the month was 77,728 tons, carrying a bullion value of $1,318,199. This production is 1,000 tons in advance of that of September, with an excess valuation of $21,500. Quite an increase in tonnage over the previous month is shown by the United States Reduction & Refining Company, and gains appear all the way dowu the line of the local plants.

Salt Lake City, Utah.—Dividends from the Utah mines thus far this year amount to $5,169,687. This is from the mines alone, and does not take into consideration the profits from the International, American, and United States smelters and allied interests, which derive their profits from the local mines and from properties owned by these companies.

COMPANY NOTES

DOMINION STEEL.

Mr. J. H. Plummer presided at a meeting of Steel directors on Nov. 1st. Those preseut were: Sir William C. Van Horne, Hon. Robert Mackay, George Caverhill, Hon. R. Dandurand, Sir H. Montagu Allau, F. L. Wanklyn, William McMaster, W. G. Ross, and Jas. Reid Wilson.

The president gave the Steel Corporation returns for the month of October: Pig iron, 24,356 tons; steel ingots, 29,675 tons; rails, 15,587 tons; rods, 6,817 tons.

Mr. Plummer also stated that matters were progressing very satisfactorily at Springhill, the output of coal being larger than before the strike began. One day last week the output reached 1,600 tons.

STATISTICS AND RETURNS

WEST AFRICAN GOLD YIELD.

The West African Chamber of Mines announces that the gold yield of the colony during September was 26,717 ozs., valued at £109,039, an increase of 1,332 ozs., or £5,286, compared with the preceding month. Last month's return is a record as regards value, being £2,796 above the previous highest, which was £106,243 in March, 1908.

COBALT ORE SHIPMENTS.

Following are the shipments from the Cobalt camp for the week ending Nov. 3, and those from Jan. 1, 1911, to date:

	Nov. 3. Ore in lbs.	Since Jan. 1. Ore in lbs.
Badger	.....	55,200
Bailey	.....	40,000
Beaver	.....	1,520,217
Buffalo	.....	2,212,863
Chambers-Ferland	64,000	1,150,900
City of Cobalt	64,000	727,980
Cobalt Lake	114,430	3,760,920
Cobalt Townsite	53,004	1,142,514

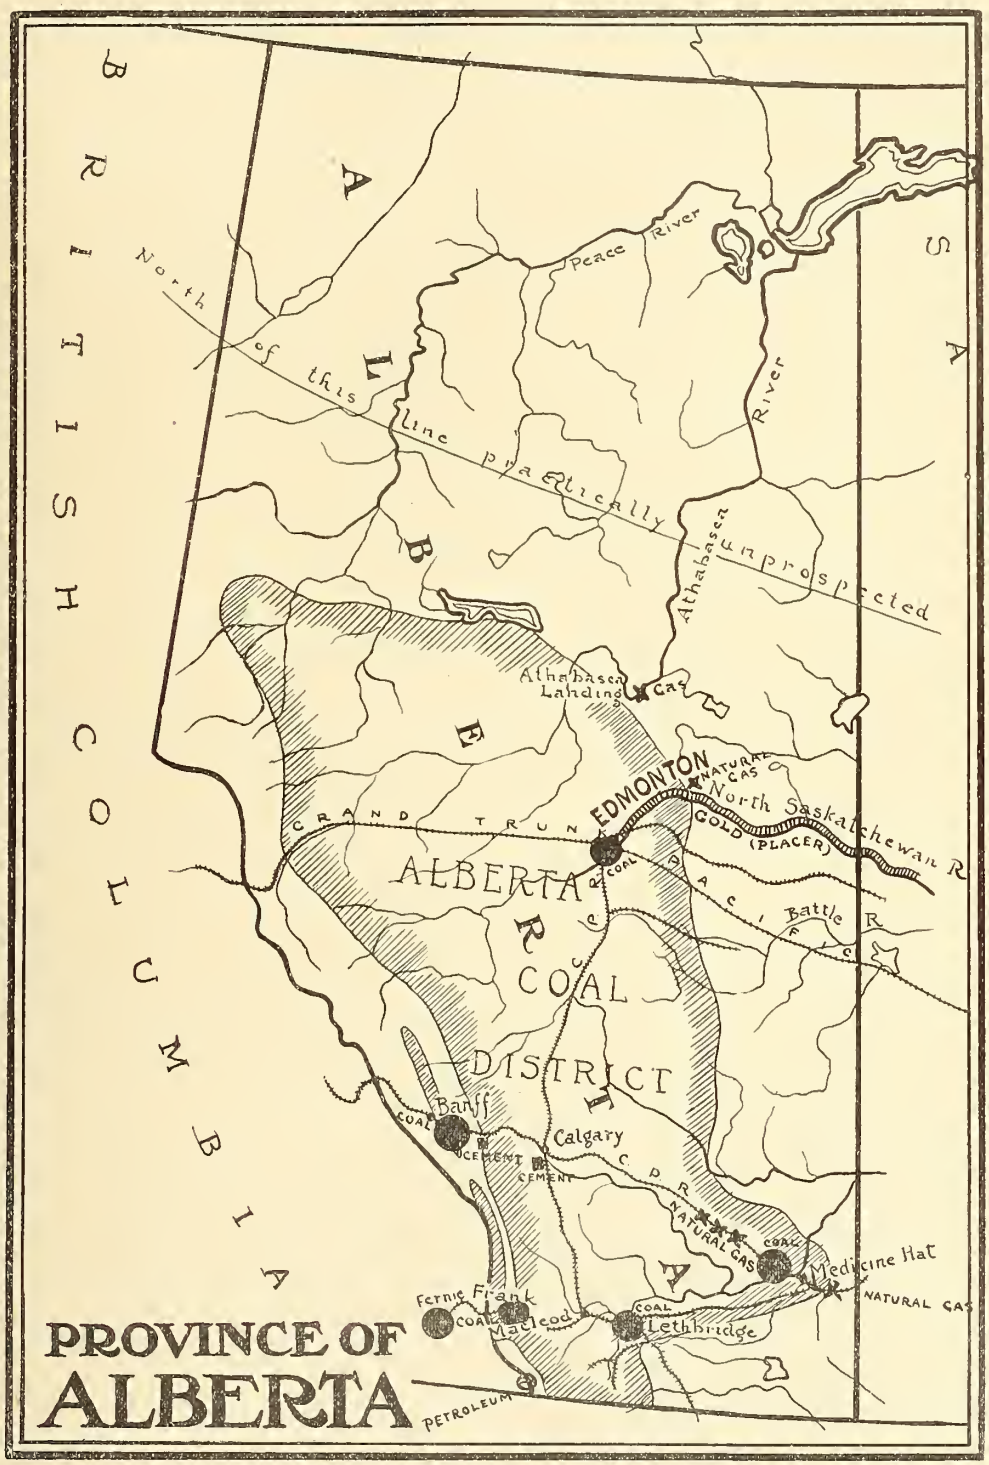
MINERAL MARKETS.

Acids—
Muriatic, tank cars, $1.15 to $1.55 per 100 pounds.
Nitric, $0.04 to $0.05 per pound.
Sulphuric, $0.01 per pound.
Chrome Ore, 50 per cent., ton of 2,240 lbs., $15.
Fire Clay, $2.50 to $5 per short ton.
Fluorspar, lump, $9 per long ton.
Fluorspar, ground, $12 to $15 per long ton.
Graphite, lump, 4 cents to 10 cents per pound.
Gypsum, short ton, ground, $4 to $7.50 per ton.
Magnesite, crude, 95 per cent., $7 to $8.50 per long ton.
Molybdenite, commercially pure, 25 to 30 cents per lb.
Pyrite, lump, arsenic free, 10 to 12½ cents per unit.
Pyrite, fines, arsenic free, 8 to 11 cents per unit.
Tungsten ore, 50 per cent., $7.70 per unit.

TORONTO MARKETS.

Nov. 9.—(Quotations from Canada Metal Co., Toronto):
Spelter, 6.50 cents per pound.
Lead, 4.25 cents per pound.
Antimony, 7 to 9 cents per pound.
Tin, 43 cents per pound.

Nov. 6.—Tin, Straits, 41.75 cents.
Copper, Prime Lake, 12.50 cents.
Electrolytic copper, 12.40 to 12.45 cents.
Copper wire, 13.50 cents.
Lead, 4.25 to 4.30 cents.
Spelter, 6.40 cents.



Copper, casting, 12.85 cents per pound.
Electrolytic, 12.85 cents per pound.
Ingot brass, 7 to 12 cents per pound.

GENERAL MARKETS.

Coal, anthracite, $5.50 to $6.75.
Coal, bituminous, $3.50 to $4.50 for 1¼ inch lump.

Sheet zinc (f.o.b. smelter), 8.00 cents.
Antimony, Cookson's, 8.00 cents.
Aluminium, 19.00 to 19.50 cents.
Nickel, 40.00 to 45.00 cents.
Platinum, ordinary, $46.00 per ounce.
Platinum, hard, $48.50 per ounce.
Bismuth, $1.80 to $2 per lb.
Quicksilver, $46 per 75-pound flask.

CANADIAN STEEL PRODUCTION.

1st Half 1911.

Steel rail production fell off about 8 per cent. during the six months, as compared with the corresponding period in 1910, being 161,635 tons.

The following table gives the production of pig iron, steel ingots and steel rails during the first half of 1911 and 1910, respectively:

	First 6 mos., 1911.	First 6 mos., 1910.
Pig iron (tons)	400,170	344,783
Steel Ingots (tons)	374,793	338,966
Steel rails (tons)	161,635	174,592
Grand total	936,598	860,341

The one unsatisfactory feature of the iron and steel situation in Canada is the demoralized condition of prices on account of the competition in the United States.

GENERATORS and MOTORS FOR ALL PURPOSES

A Man's Value

to his family or those dependent upon him is measured by his earning capacity. As death entails the loss of that earning capacity, every man should make provision for his loved ones in order to make good to them the financial loss that would ensue. This is the purpose of life insurance, and no man is blameless whose life is not insured.

It makes no Difference

whether you mill, smelt or ship your ores you must have assays and analyses of unquestionable accuracy reported to you in the shortest possible time. Our equipment is especially designed to meet these requirements.

WE also test ores in a practical way to determine just what metallurgical process is best adapted to it to secure the highest commercial results. Write us for prices for your particular problem.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

DEPARTMENT OF MINES. GEOLOGICAL SURVEY.

PUBLICATIONS

The Geological Survey has published maps and reports dealing with a large part of Canada, with many local areas and special subjects.

A catalogue of publications will be sent free to any applicant. A single copy of a map or report that is specially desired will be sent to a Canadian applicant free of cost and to others at a nominal price. The applicant should state definitely the precise area concerning which information is desired, and it is often of assistance in filling an order for a map or report if he states the use for which it is required.

Most of the older reports are out of print, but they may usually be found in public libraries, libraries of the Canadian Mining Institute, etc.

REPORTS RECENTLY ISSUED:

CANADA

1085. Descriptive Sketch of the Geology and Economic Minerals of Canada. Accompanied by a geological and mineral map of Canada, by G. A. Young and R. W. Brock.

NOTE.—Maps published within the last two years may be had, printed on linen for field use. A charge of 10 cents is made for maps on linen.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon. Letters and samples that are of a Departmental nature, addressed to the Director may be mailed O.H.M.S. free of postage.

Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.

BRITISH COLUMBIA

The Mineral Province of Western Canada

Has produced Minerals valued as follows: Placer Gold, $71,213,103; Lode Gold, $60,811,067; Silver, $31,095,602; Lead, $24,645,605; Copper, $60,743,405; Other Metals (Iron, Zinc, etc.), $1,083,172; Coal and Coke, $114,012,596: Building Stone, Brick, etc., $10,593,100; making its Mineral Production at the end of 1910 show an

Aggregate Value of $374,197,650.

In 1910 the quantity of Ore mined was 2,216,428 tons, and of coal 3,139,235 long tons. The value of Minerals produced that year was: Placer Gold, $540,000; Lode Gold, $5,533,386; Silver, $1,245,016; Lead, $1,386,350; copper, $4,871,512; Coal and Coke, $11,108,335; Other Minerals, $1,692,473, making the

Total Value for 1910, $26,377,066.

Lode mining has only been in progress for about eighteen years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those in any other Province in the Dominion, or any Colony in the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with mining Reports and Maps, may be obtained gratis by addressing

THE HON. THE MINISTER OF MINES
VICTORIA, B. C.

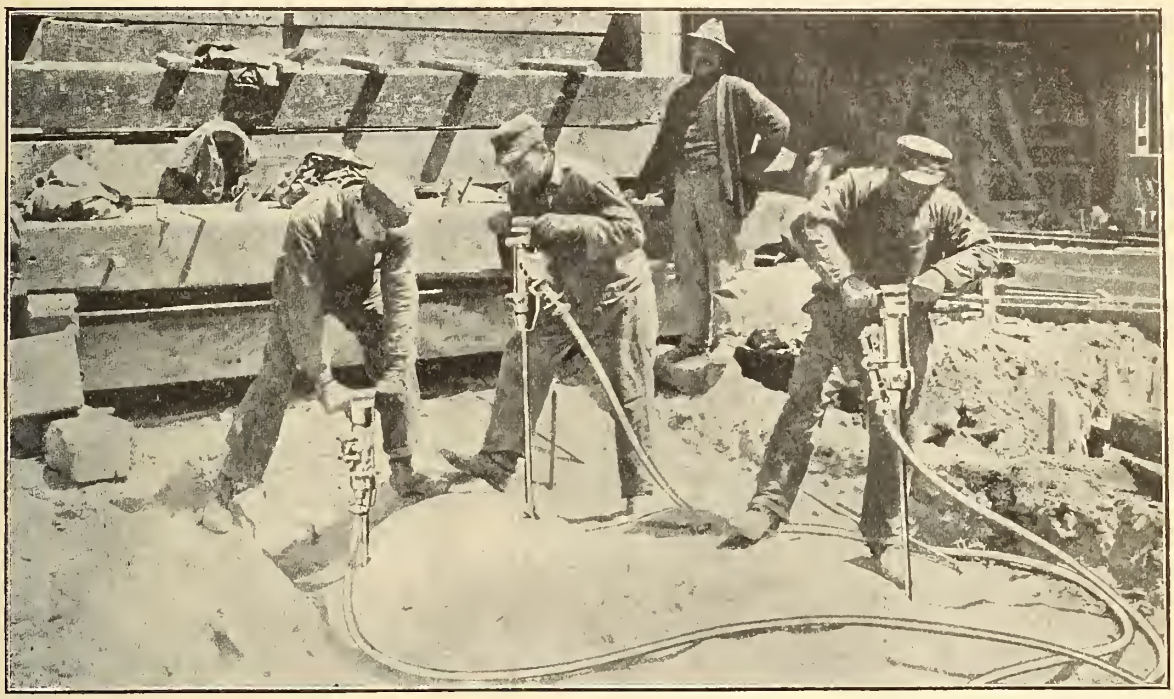
The MCKIERNAN-TERRY CLASS "B" HAMMER DRILL



"Three "Busy Bees" at work on the New York Subway Excavation."

Are you sinking a shaft?
Would you like to do it cheaper and faster?

If so, follow the method used by the contractors in New York, who are putting down the big shafts for the Subway Excavations.
They are using "24 McKiernan-Terry Class "B" Hammer Drills"
They call them "BUSY BEES."
These Drills will put down 8 ft. holes, either *wet or dry.*
They will bore about twice as fast as the reciprocating rock drill.
They use half as much air.
They require no setting up.
There is no time wasted.
They are BUSY all the time.
They are the last word in a shaft sinking tool.
BUY ONE AND TRY IT.

Province of Quebec

Department of Colonization, Mines, and Fisheries.

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, Etc.

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

MINERS' CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10.00 and it is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFYER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $10 an acre for SUPERIOR METALS when more than 20 miles distant from a railway and $20 an acre when less than 20 miles.

For INFERIOR METALS the prices are $2.00 and $4.00 an acre respectively.

The attention of prospectors is specially called to the territory in the North-Western part of the province of Quebec, north of the height of land, where important mineralized belts are known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, MONTREAL, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The Bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

THE HONORABLE THE MINISTER OF COLONIZATION, MINES, AND FISHERIES, QUEBEC.

Nova Scotia Mines

Gold, Coal, Iron, Copper, Lead, Tin, Manganese, Tungsten, and other minerals.

The Gold District covers more than three thousand square miles. Millions of dollars worth of gold have been taken from the gold fields of Nova Scotia and millions of dollar's worth remain for recovery.

Gold mining in this Province offers good inducement for investment. Labor is cheap and plentiful: timber and fuel are abundant.

Large deposits of iron also are known to exist at various places in the Province; and considerable mining has been done in connection with this mineral, the ore being used locally and shipped to foreign ports.

Among the most important minerals occurring in economic quantities may be mentioned, Coal, Gold, Silver, Manganese, Leadsilver, Copper, Barytes, Mineral Pigments, Gypsum and Tungsten.

Licenses are issued for prospecting for Gold and Silver for a term of twelve months. The licenses are for areas 150 by 250 feet, and can be obtained for 50c. an area.

Leases can be secured for $2. an area, for a term of forty years; subject to annual rental of 50c. an area.

Licenses to search over five square miles, for a period of eighteen months, for minerals other than gold and silver, cost $30.

Leases for three renewable terms of twenty years each can be obtained for $50., and are subject to a yearly rental of $30.

Royalties are as follows:—

Gold, two per cent on the gross value thereof; Copper, four cents a unit; Lead, two cents a unit; Iron, five cents a ton; Tin and Precious Stones, five per cent; Coal, ten cents on every long ton sold or removed from the mine.

Copies of the mining law can be had gratis, by applying to the Department of Public Works and Mines, Halifax, Nova Scotia, or to Mr. John Howard, Agent General for Nova Scotia, 57a Pall Mall, London, England.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. W. H. HEARST,
Minister of Lands, Forests and Mines,
Toronto, Canada.

THE "ROYAL LINE"

To Europe in

Less than Four Days

LAND TO LAND

The St. Lawrence Route to Europe by the ROYAL LINE shortens the ocean voyage to less than four days, and affords the traveller two days of delightful, sheltered sailing down the great St. Lawrence with its never ending panorama of beautiful scenery and historically famous points. The splendid triple turbine steamers

ROYAL GEORGE and ROYAL EDWARD

hold all speed records and afford the most luxurious accommodation in the Canadian-European service. The English Port, Bristol, is only two hour's run to London by the special boat trains which meet the Royal Line Steamers on arrival.

For further information see nearest Steamship Agent, or the Canadian Northern Steamships Limited.

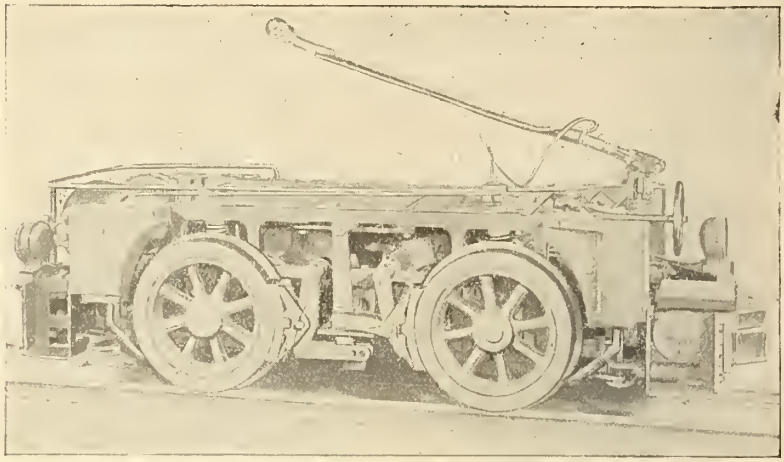
Baldwin-Westinghouse Mine Locomotives

Figure how much animal haulage costs you a month, feeding, shoeing, and the pay of drivers, then let us tell you how much less it costs to maintain Baldwin-Westinghouse Mine Locomotives to do the same work better.



Baldwin-Westinghouse Electric Gathering Locomotive

You never hear of a mine going back to animal haulage after having once used Baldwin-Westinghouse Mine Locomotives. The contrast is too great all along the line; in efficiency, cleanliness and economy of maintenance. We can give you some figures as to the savings effected by electric mine haulage that will appeal to you.

MINING AND SCIENTIFIC PRESS

Controlled by T. A. Rickard — Established 1860 — H. Foster Bain, Editor — Published weekly — Thomas T. Read, Associate Editor

In every issue valuable articles are published on mining, metallurgy, and geology, the latest news from special correspondents at the principal mining centers, letters giving the ideas and experience of successful men, and other items of useful knowledge.

THE MINING MAGAZINE
Established September, 1909
T. A. RICKARD, Editor — Published monthly at London, England

A monthly magazine is the natural corollary of a technical weekly. It permits of more deliberate and more extended notice of matters concerning which the news element is less important.

The Mining Magazine includes a review of the world's progress in mining, metallurgy, and economic geology, written by men who have personal knowledge of the regions and conditions discussed.

COMBINATION RATE: To new subscribers to both papers in	Combination yearly rate

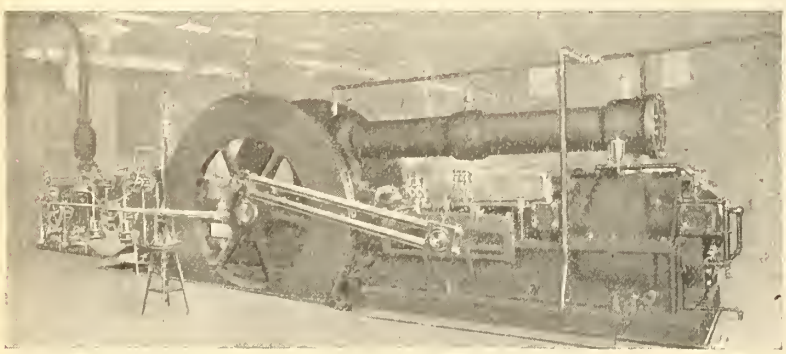
YOU CAN AFFORD CHEAP AIR

ARE YOU GOING TO BUY AN AIR COMPRESSOR? IS THE COST OF YOUR AIR ANY OBJECT?



The price of a cross-compound Corliss machine of the first class may seem beyond your means. But before you select a low priced slide valve compressor, which will COST YOU THREE TIMES AS MUCH AS THE "CORLISS." EVERY DAY FOR COAL, read the rest of this.

You can afford proper fuel economy, and keep your air cost down where it belongs, by selecting a SULLIVAN TANDEM CORLISS TWO STAGE COMPRESSOR. These machines have every advantage that the cross compound has, but the size, weight and price are all less. They cost us less to build, and sell, because they are simpler, have fewer working parts and are carried in stock sizes. They cost you less to install, because they weigh about a third less than the cross compound and require about half the foundation and floor space.

We have convinced many critical engineers; now we are getting their repeat orders.

Amatite ROOFING

Mineral Surfaced— Needs No Painting

EVERYTHING about Amatite appeals to the man with common sense. He can see its superiority at once—the real mineral surface *which never needs painting;* the two layers of Pitch which is the greatest waterproofing material known; the two layers of heavy Tarred Felt—all these contribute to the popularity of Amatite.

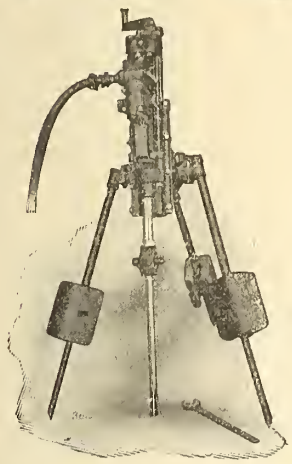
We can make Amatite better and cheaper than anyone else on account of our greater facilities, and consequently we sell it at a surprisingly low figure.

Simply the fact that it needs no painting is enough to make a man sit up and take notice especially the man who has spent time and money in painting and repainting smooth surfaced roofings.

Write to-day for further information.

The Paterson Mfg. Co., Ltd., Montreal, Toronto Winnipeg, Vancouver, St. John, N.B. Halifax, N. S.

"LITTLE GIANT"
ROCK DRILLS



In the Rand "Little Giant" Drill the valve motion is positive and simple. The main valve is not dependent upon the motion of another valve for its operation but is thrown independently and positively by a rocker.

The rocker does not ride heavily on the piston but is suspended over, and lightly guided by it.

The Little Giant Valve motion is quick, positive and economical and ensures a wide open port on each stroke of the piston.

These large free ports mean, a powerful uncushioned blow, with a wonderful penetrative effect.

You cannot buy the equivalent of a RAND for less money.

CENTRIFUGAL PUMPS
FOR MINE WORK

The Waterous Centrifugal Pump is especially adapted for mine drainage. The vertical type, illustrated herewith is built in sizes up to 14" discharge opening in Submerged and Dry-pit styles.

It is light, simple and compact, built with few parts, very strong and not likely to get out of order.

Any one can operate it. It can be left in charge of an unskilled laborer and will run the full shift without a murmur.

Its extreme compactness and the fact that any kind of drive, engine, motor or belt can be used, makes it especially adaptable for mine work. Complete description of construction and working capacity, given in our Bulletin No. 200.

Waterous Engine Works Co., Ltd., Brantford, Canada

SWASTIKA Public Notice

Our attention has been drawn to advertisements which have appeared in some of the Toronto papers over the name of CHAS. A. STONEHAM & CO., of 23 Melinda Street, Toronto, also to a circular purporting to be issued by the same parties from their Chicago office at 178 West Jackson Boulevard, also to a circular letter dated 6th November, 1911 and a pamphlet enclosed therein, purporting to emanate from their Chicago office. We feel it to be our duty to the public to state that CHAS. A. STONEHAM & CO. do not in any way represent us and have no authority whatever to make any statements regarding the conduct of our business or the management of our mine. We do not endorse any of their statements and they are not in any way in the confidence of our directorate or mine management and the public are warned accordingly. The company has also caused CHAS. A. STONEHAM & CO. to be notified by its solicitors to desist from any further publications relating to this company's affairs in any and every way. The affairs of this company have always been conducted with an eye single to an honest, clean and capable management and the directors feel that this will be appreciated by the investing public generally.

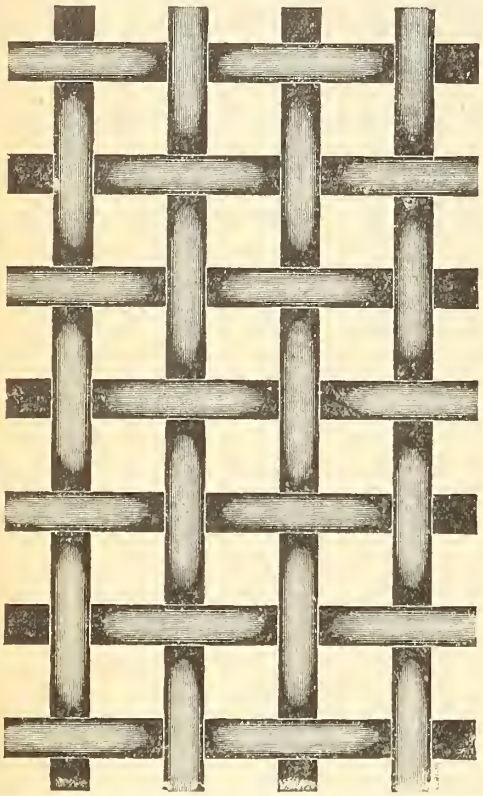
IT STANDS THE WEAR



Our Coal Screening is the kind to use where satisfactory grading of coal is to be accomplished.

Throughout every coal region in Canada

GREENING COAL SCREENING

is daily demonstrating its superiority.

The fabric is woven of specially hard drawn steel wire from our own mills. Our method of double crimping the wires insures openings that are both square and uniform, while at the same time adding greatly to the strength of the screen, and preventing the dis placement of the wires in use. We can ship Greening's Coal Screening promptly from stock, or can make screens to order with agreeable speed and accuracy.

Why the C.P.R. North Toronto Route to Ottawa and Montreal is the Logical One

The train leaves as follows:

Leave North Parkdale - - -	9.15 p.m.	Leave West Toronto - - - -	9.30 p.m.
Arrive North Toronto - - -	9.40 p.m.	Leave North Toronto - - -	10.00 p.m.
Arrive Ottawa, 6.50 a.m.		Arrive Montreal, 7.00 a.m.	
Daily.		Double Electric Berth Lights.	

¶ The residents of Toronto are adjacent to either North Parkdale, West Toronto or North Toronto stations, same being easily accessible and close to residential districts.

¶ The North Toronto route is over an hour faster and overcomes a long hill climb for the train out of Toronto obviating any inconvenience and ensuring early arrival at Montreal and Ottawa.

¶ The roadbed has been improved till it is unexcelled in Canada. Practically half the line is double tracked.

¶ The equipment is "Canadian Pacific Standard," a synonym for the "best" and attentive porters, ensure efficient service.

THE

MINING MANUAL

1910

BY WALTER R. SKINNER.

The Standard Reference Work on Mines.

Price 17/- Net Post Free (Abroad).

1,500 pages. In demy 8vo, handsomely bound in RED cloth.

The best and most complete compilation of statistics in connection with the mining industry published.

A record of information concerning

MINING COMPANIES

(Gold, Diamond, Silver, Copper, Tin, Iron, and other Mines, Collieries, Land, Exploration and Mining Investment Concerns, &c.)

Arranged in three sections—

Australasian, African, Miscellaneous,

Preceded by Tables of Crushings and followed by lists of Mining

DIRECTORS, SECRETARIES, MINING and CONSULTING ENGINEERS and MINE MANAGERS.

Their Names, Addresses, and Descriptions, and Names of the Companies with which they are connected, and a

DICTIONARY OF MINING AND OTHER TERMS.

THE MINING MANUAL for 1910 contains particulars of over 3,120 Companies arranged in three sections, 315 Companies being AUSTRALASIAN (including Western Australia, Queensland, Broken Hill, Deep Leads, New Zealand and Tasmania); 985 AFRICAN (including Transvaal, Rhodesia, Cape Colony, Natal, West Africa, Nigeria, &c.); and 1,820 MISCELLANEOUS (including Mexico, India, America, Europe, Siberia, &c., and the Coal, Iron, Tin and other Mining concerns of the United Kingdom). The particulars given of each Company include the Directors and other officials; date of establishment; seat of operations; description of the property, with the purchase consideration; plant erected or in course of erection; present working results; ore reserves; details of capital; calls; dividends paid; and the financial position as disclosed by the accounts. Highest and lowest prices of the shares for the last four years, also latest price.

The Index, which forms a highly important feature of the book, contains the names of over 5,300 Companies, consequently active, private or dormant companies can easily be traced.

Crushing tables and Gold Outputs from the principal mines are given at the commencement of the volume, showing tons treated monthly, results obtained, and yield per ton; also annual yields.

Lists of Directors (8,000), Secretaries (1,900, Mining and Consulting Engineers and Mine Managers (1,400) include their addresses and descriptions and names of the Companies with which they are connected.

To be obtained from all Booksellers, or direct from the Proprietor,

AN INDICTMENT OF CONSERVATION.

In the course of a characteristic address, delivered before the American Mining Congress, Mr. Horace J. Stevens gave an unvarnished opinion of the conservation movement in the United States.

After pointing out first the inevitable tendency in copper mining towards commercial consolidation, Mr. Stevens proceeds to handle the conservationist. Not only does he wear no gloves—he goes so far as to adopt brass knuckles. Here is a specimen of his denunciatory eloquence: "The greatest present menace "to the copper industry in the United States is a men-"ace that is common to all branches of mining. The "entire American industry is threatened by men oper-"ating under the names of progress and reform, . . ". . but who are political economists of the Stone "Age, and first cousins, in mental capacity, to the "Troglodytes."

Extravagant and intemperate as Mr. Stevens' invective may be, there is certainly a large degree of right on his side. For instance, the great Washoe smelter may be closed on account of the fact that the smelter fumes are damaging small tracts in the Federal forest reserves, timber that Mr. Stevens describes as being suitable possibly to furnish good lodge-poles for Indian tepees.

The most vital point, however, of Mr. Stevens' address refers to the Guggenheims. These much abused persons, at an expenditure variously estimated at from $13,000,000 to $25,000,000, built 195 miles of railway in Alaska to reach their Bonanza copper-gold mine. The gross value of both measured and probable ore reserves in this mine falls below $13,000,000, and, according to Mr. Stevens, the largest net profits to be hoped for from the operation of the mine will not exceed $5,000,000. Although the railway passes through regions that contain large and valuable deposits of bituminous coal, the Federal Government, acting on the advice of the conservationists, has prohibited the development and use of this coal. Hence the railway and the Alaskan settlers generally are compelled to use coal imported at high cost from British Columbia.

The Government's withdrawal of large tracts of oil, coal, and phosphate land is condemned with equal vigour. The next logical step, Mr. Stevens predicts, will be the withdrawal of iron, copper, lead, zinc, silver and gold lands—"a cleverly devised socialistic "propaganda."

To the argument that the iron ore resources of the United States are being too rapidly depleted Mr. Stevens opposes the assertion that in a single county of Michigan there is more iron ore than any "professional

conservationist'' has estimated to exist in the whole world.

The root of the whole evil is attributed to the fact that Congress has endowed the executive departments of the Government with power to promulgate rulings that have the force of law; the consequence being that the miner, although he may have complied with all known statutory requirements, may find himself arbitrarily deprived of his property by the officials of the forestry service. A Canadian analogy holds here in the case of the western coal lands that are administered by the Department of the Interior at Ottawa.

We have indicated enough to show the purport of Mr. Stevens' address. Whilst his language is far from being dispassionate and while his attitude does not remotely resemble the judicial, yet he voices a growing belief that many blunders and not a few political sins are being committed in the name of conservation.

THE ENGINEER.

In a scholarly, polished, and eloquent address before the members of the Toronto Engineers' Club, President Falconer, of the University of Toronto, traced the evolution and the meaning of the profession of engineering. With apt allusions he illustrated the successive historic phases of the engineer's function. He was listened to with rapt attention.

Admirable in tone and in content as was President Falconer's address, there was, unhappily, one strange gap. He touched illuminatingly upon architecture; he glanced over the field of civil engineering; he referred to the electrical engineer; he mentioned the mechanical engineer. But never a word did he say of the mining engineer, whose profession is the very plinth of the whole science of engineering.

Now this was a very serious sin of omission. We do not particularly blame President Falconer. But we cannot refrain from seizing on the occasion to relieve our editorial chest.

President Falconer's historical allusions were numerous and apposite. He drew on Biblical narrative, and on the history of Greece and Rome. We marvel that in reading Holy Writ he could have missed the mining man. Time does not permit us to be specific. But President Falconer will, no doubt, remember having read of Tubal Cain, who, by implication at least, was a mining and metallurgical engineer. Is there not, also, in the book of Job, specific reference to mining? Chapter 28 is a lordly picture of mining. What, moreover, of Hiram, King of Tyre?

In fact, although sacred and profane literature is dotted with innumerable references to mining and the mining engineer, there is a singular convention on the part of orators and publicists to ignore them. The mining engineer is treated as a negligible quantity.

All the high eulogies bestowed by President Falconer upon the civil engineer were, no doubt, deserved. But why overlook him who provides all engineers with his materials of construction? How would the railways, the canals, the buildings, the bridges, the ships, and every other product of human ingenuity be constructed had not the mining engineer, through centuries of laborious effort perfected the means of extracting ores from the mine and metals from the ore!

We suggest that President Falconer, as a salve to our wounded self-esteem, give us a stirring address on the mining engineer's relation to the world's history.

AMALGAMATED ASBESTOS.

The decision of the directors of the Amalgamated Asbestos Corporation to default payment of the interest on their consolidated bonds, came as no surprise to the public. The earnings of the Corporation could not possibly provide for a 5 per cent. payment on $8,000,000.

There is now no other recourse than financial reorganization. While the mines are in excellent condition, the market is certainly profoundly depressed. But even were the asbestos market active, there is little ground for thinking that reorganization of the Corporation's finances could be much longer postponed.

Those who followed the early history of Amalgamated Asbestos will be given ample confirmation of the belief that far too great a load was placed upon the Corporation by the promoters. But the blame rests not altogether upon the shoulders of the promoters; a large part of it belongs to those technical men who subscribed to the original overdone prospectuses.

There is little to be gained in recriminations. Nor is it either fair or proper for those newspapers that most avidly supported the promoters to assume a hostile attitude now. On the other hand, it is desirable that the directors of the Corporation be given every assistance in reducing its financial obligations to a rational level.

It may be mentioned here that the Canadian Mining Journal will take no notice of anonymous letters. Several such, in which abuse has been heaped upon the Corporation, have reached our office.

OFFICERS FOR THE INSTITUTE

Before January 1st, 1912, all nominations for offices in the governing body of the Canadian Mining Institute, must be in the hands of the secretary.

Circumstances make it more than ordinarily important that next year's President, who, it is assumed will hold office for two successive years, be a man of outstanding reputation. Not only must he have at heart the good of the Institute, but he must possess in large degree those qualities that spell popularity. As President he will have to undertake the onerous duties of chairman and of ex-officio member of numerous com

mittees. He will be called upon to act the part of host, entertainer, adviser, and peaee-maker.

In view of the faet that the summer of 1913 will be marked by the presence in Canada of a most formidable gathering of scientists, the selection of the presiding officer should be given much thought. The International Geological Congress will bring to Toronto some hundreds of geologists and mining men from many parts of the world. Practically all the leading spirits of the profession will gather here. In separate parties they will tour through all Canada.

In organizing and handling this large series of excursions, consummate eare, taet, and business acumen will be required. And the bulk of this responsibility must be assumed by the President.

There is also another serious eonsideration. The Institute has undertaken, through a strong committee, to revise and eodify the Dominion mining laws. This will be the largest feature of the coming year's work. If the President be not thoroughly eompetent to handle this complicated matter, if he be not conversant with the requirements of the case, then the battle for right legislation will be foredoomed to failure.

We urge upon the members of the Canadian Mining Institute the necessity of pondering long and well before casting their votes. Above all no nominations should be made nor should votes be cast for seetional or personal reasons. The Institute is striving to become a national body, and is, in some measure, succeeding. The good of the whole society must be considered first and solely.

THE SUMMARY REPORT OF THE MINES BRANCH FOR 1910.

From the Director's General Report, which preeedes the special staff reports, we gather an outline of the work aceomplished and begun during the calendar year, 1910.

Dr. Haanel asserts preliminarily that the labours of the Mines Branch are becoming more practical every year. As evidence of this he instances the large demand for the monographs published by the Branch.

Important amongst the new investigations begun during the year was the study of the building and ornamental stones of Canada. A summary of Dr. W. A. Parks' monograph on the building stone of Ontario is included in the present volume. But the strongest feature is the ineeption of systematic work on the character, handling, use, and storage of explosives.

Fuel testing, iron ore concentration, experiments in the reduction of refraetory zinc ores, and magnetometric surveying are other activities of the Branch.

The preliminary reports presented in this summary cover a wide range of subjects. Iron ores, molybdenum ores, eopper mining, miea deposits, peat bogs, etc., etc., are written up by members of the staff. In fact, the Branch appears to have taken stronger and deeper root and to have become imbued with a decidedly vigorous spirit.

The CANADIAN MINING JOURNAL strongly endorses Dr. Haanel's plea for an adequate central office wherein all the technical staff of the Branch can be properly aecommodated. It is to be hoped also that larger appropriations will be secured for the new Explosives Testing Station.

It is with some astonishment that we notice in the accountant's statement an item signifying that the sum of $25,361.91 was a balance "unexpended and lapsed." The Branch will do well to spend every cent it can secure, and, if possible, run itself into debt. Its total appropriation for 1910 was only $113,303.65. To carry out future plans on a becoming scale this should be multiplied by five. An unexpended balance in such a department is eontrary to all precedent.

ELEMENTARY ECONOMICS.

A prominent mining man, in the course of an interview with the CANADIAN MINING JOURNAL, stated that he had twice or thrice offered to pay the price asked for certain prospects in Porcupine, on condition that he first be permitted to spend a considerable amount of money in investigating. In each ease this offer was unqualifiedly rejected. The person in question was amply able to carry out any undertaking that appealed to him. He was not only ready and willing but anxious to be responsible for the preliminary development of any reasonably promising claim. But everywhere he found owners asking impossibly high prices and imposing impossibly rapid terms.

This is one general cause of the present decline of public interest in Porcupine. Another incidental cause is the suppression, or non-publication of Mr. Robbins' report on the Hollinger. Still another is the superfluous and glittering generalities that are being published about the Dome, ostensibly from headquarters.

On its own merits Porcupine must stand or fall. Assuredly it needs sane advertising. More assuredly it does suffer from indiscreet booming.

It is high time that the mine owners and operators of Porcupine get together and devise a practicable scheme of publicity.

THE MOLYBDENUM ORES OF CANADA.

Dr. T. L. Walker has added another monograph to his valuable contributions to the literature of Canadian ores. Under the auspices of the Mines Braneh he has investigated the molybdenum ores of the Dominion and has presented the results of his observation in the latest publication of the Branch.

Dr. Walker visited most of the best known Canadian deposits. Of these he gives a list of twelve that appeared to him to be most promising. Quebec, Ontario, and British Columbia are represented in this list.

Molybdenum is one of the least exploited metals. Its principal ore, molybdenite, presents peculiar difficulties in any attempt to concentrate it. Coneen-

trating tables do not give uniform results. Indeed, ordinary methods of milling have never, so far as we are aware, proved entirely satisfactory when applied to ores of molybdenum. The vacuum process appears to have given good results, but we doubt if the trials have been complete. Possibly dry concentration may prove effective. But there remains much for the investigator to do, and the field is inviting.

The world's production of molybdenum amounts only to a few hundred tons, and is subject to pronounced variation. Were the output larger and consistent there is no doubt that a steady and profitable market would be developed.

Of known Canadian molybdenite deposits, the most promising are in Quebec, Ontario, and British Columbia. The ores reported upon range in molybdenum content from 0.5 to more than 10 per cent. of molybdenum. The principal deposits occur in quartz veins, pegmatite dykes, and near the contact of limestone with intrusive granite or pegmatite. Prospecting for the mineral is not surrounded with the difficulties that characterize gold, silver, and other metals.

Dr. Walker concludes his monograph with the remark that development is often hindered by reason of the prohibitory prices asked by property owners. This is lamentably true.

A DEEP SHAFT IN WET GROUND.

A Montreal firm has been awarded the contract of sinking a 200-foot concrete shaft through sand, clay, and gravel at St. Albert, near Edmonton, Alberta. The details are interesting.

The coal lies at a depth of about 300 feet. It is overlaid by 100 feet of shale in which occur occasional seams of coal and sandstone. Over this is imposed a body of clay and very wet sand and gravel, 200 feet thick.

The attempt was made some time ago to sink an ordinary timber shaft. At a depth of 82 feet the work was abandoned. It was found impossible to hold the shaft and to take care of the water.

The proposed new shaft will be built of reinforced concrete from the surface to the shale. Here it will be completely sealed. Thus an absolutely fireproof and water tight shaft will be secured.

THE INSTITUTE IN PORCUPINE.

Every effort is being made to organize a strong branch of the Canadian Mining Institute in Porcupine. With this end in view a meeting is to be held at South Porcupine on December 16th. It is hoped that every mining man within reach of the place of meeting will attend this first gathering.

A few short papers are to be read on the evening of the 16th, after the regular business has been transacted. On the following day all who desire to do so may be shown over the camp.

Dr. Frank Adams, the President of the Institute, will be the guest of honour. Accommodation will be secured at the various mines for visitors who notify the secretary in time.

CHAS. A. STONEHAM & CO.

The exaggerated mining news items published by Chas. A. Stoneham & Co. have bred much mischief. One mining company has adopted the expedient of advertising in the daily papers the fact that it cannot be held responsible for any statements made by Chas. A. Stoneham & Co.

It would be a very wholesome thing if every mining company whose shares are listed on Canadian exchanges were to make a similar protest. Unclean parasites, and this describes the firm of Chas. A. Stoneham & Co., could thus be promptly choked to death.

A WARNING.

Several letters of enquiry regarding the Canadian Mining Record have reached our office. To set correct certain misapprehensions it is well that we state specifically that the Canadian Mining Record has no possible connection with the Canadian Mining Journal. If we are not mistaken, the Record, which was published in Toronto, has ceased to exist.

EDITORIAL NOTES.

The Government of Western Australia employs one chief inspector and a staff of 18 men to control the storage and use of explosives.

A new mineral has come to light. An Ottawa paper announces that Mrs. Ella Rawles Reader, a lady who is supposed to be mining zinc on Calumet Island, has struck a vein of "plumbuganite." If Mrs. Reader evolved that euphonious name she deserves more than a little credit.

The writing of prospectuses is an art that can be acquired only by long experience. It is rarely that one sees a properly balanced presentation of facts and opinions. The tendency is, of course, so to use the engineer's report as to give a highly favourable view of any enterprise. A result is that many engineers are falling into the habit of making their reports serve the purpose of the prospectus. This is a lamentable tendency, a tendency that should be guarded against most rigidly.

Canadian orders, totalling upward of 50,000 tons of pig iron, have been placed in the United States. Deliveries are spread over six months.

Mr. Hugh S. de Schmid, reporting on the mica deposits of Ontario and Quebec for the Mines Branch,

Ottawa, lays stress upon the fact that the average unit value of Indian mica imported into Great Britain shows a maximum variation in five years of only $119.44. On the other hand the corresponding maximum variation for Canadian mica is $691.97. This indicates the need of grading and standardizing the Canadian product.

CORRESPONDENCE

Editor Canadian Mining Journal:—

Toronto.

Sir,—Since the publication of Mr. Hedley's most appropriate views in reference to the legislature of mining enterprises, I have been looking forward to your journal carrying this to some issue, but since the 1st ult. I note that it has not been further commented upon.

May I therefore be permitted to pass a short criticism on the subject, as through your journal I feel that something tangible may result?

In a condensed form, the proposal is to eliminate, as far as possible, the discreditable floating of mining propositions, wherein the subscriber to such company's stock has not reasonable assurance of

1st—Commercial ore.
2nd—Capitalization on sound basis.
3rd—Good management.
4th—Promoters' remuneration under control.

Before entering into a discussion on the foregoing, it will surely be agreed that the capitalization, and promoters' remuneration of most mining enterprises, are not directly within the province of consulting or advising engineers, I will, therefore, first deal with what vitally concerns the mining engineer.

The divergence of even expert opinion on an already developed mine is well known, so to even a greater extent would be the difference of opinion in the case of a prospect, or unproved arrears, but what irritates, is the publishing of reports by promoters when one probably knows, from actual experience, or other authentic reports, that the statements on the part of the promoter are not only misleading to the outside investor, but that there is little hope of commercial ore, and in some instances, mineral is non-existent except in traces.

To me, the blame is not entirely with the promoter, and a little closer co-operation on the part of mining engineers would, I think, be conducive to a better condition under this heading, and my personal views for a remedy are as follows:

That the branch members of the Canadian Mining Institute formulate a "Mining Bureau," separate to their membership to the Institute, such members to be consultants who are in no way connected with any mining enterprise, except in a professional capacity.

That under the name of "Mining Bureau," or some such title, the members would be prepared to examine and report confidentially for the endorsement, or otherwise, of the report submitted to them.

Such "Bureau" could not, of course, be formulated by the Canadian Mining Institute, but should be more or less a private organization, may be made remunerative, and its usefulness extended to the quashing of "wild-cats," as may be illustrated by Stewart and Steamboat Mountain, both of which were left for the Dominion Government to snuff out, but not until the public had invested to a large extent in each case.

I estimate that the advantage offered by such an institution would be readily taken up, by not only those who are directly interested in mining, but also by the general outside investor.

There are naturally many points for discussion on such a proposal, but with judicious handling, there should be no insurmountable difficulties.

On the question of management, I think that your proposal to have provincial examinations for mine managers, would be a means whereby the investor may be assured that he has the opportunity of having a fully qualified man in charge, but what often occurs is the appointing of a person who has had no previous experience, but who is an ornament and friend of the promoters, but as promoters generally have the ruling power, a definite solution to prohibit this appears to be almost impossible, as by legislation, a company may be compelled to have a fully qualified engineer in charge, and yet such man may be subservient to the unqualified person appointed by the promoters.

As previously stated, it is hardly within the province of the consultant, or advising engineer, to attempt to dictate as to capitalization and promoters' remuneration, but with the innumerable legitimate and excellent opportunities for the investment of capital in mining, one naturally feels that we should endeavour to rectify the present evils, and thus add to the inducements, also to see that such investment should have reasonable assurance to become remunerative.

To many of the promoters there appears an incentive for the promoter to construct his company so that he may "usher the investor in on the ground floor" while he occupies the sub-basement, and while one cannot dictate to the investing public as to what floor they should occupy, they could at least be safeguarded by placing them in possession of the details of the structure, and to apply a remedy, I would suggest Dominion legislation somewhat upon the following lines:

That it should be unlawful for any company, syndicate, or trustee to issue privately or publicly, or use literature for the purpose of securing subscriptions for shares, which shall not have therein printed—

A. Capital of the company.
B. Title the company holds.
C. Amount of promotion appropriated, and whether in cash or shares, or both.
D. Amount of shares already issued and fully paid for.
E. Shares issued but not fully paid for.
F. Balance of shares in treasury.

Such figures and statements to be as entered in the books of the company at the time of publication, and the name of the secretary to be given with registered address of the company.

I do not see that any reputable company could object to comply with the above requirements, and as most public mining flotations for the development of a "prospect," or unproven ground, are more or less speculative, the public, with the facts and figures before them, would have more confidence in taking an interest.

In any event, it would prevent the sub-basement being occupied by the promoter, while the public are tenants of the ground floor, with no knowledge of any basement existing.

In conclusion, I consider that a great effort should be made to remedy the existing discrepancies, and through closer co-operation amongst those of the profession, also through the medium of your journal, I trust progress may be reported.

Yours faithfully,

"CONSULTANT," B.C.

BOOK REVIEWS.

GRAPHICAL SOLUTION OF FAULT PROBLEMS—By C. F. Tolman, Jr., 43 pages — illustrated — flexible binding — price, $1 — Published by Mining and Scientific Press, San Francisco, and The Mining Magazine, London—1911.

Few mining engineers have made a close and comprehensive study of ore deposits. To be of practical assistance to the engineer, Mr. Tolman has sketched the principles of the graphic representation and investigation of fault problems. No other phase of mining is so in need of definition.

Mr. Tolman introduces his subject as follows:—"A "common occurrence in mining is to have a drift on "the vein meet a polished wall, on the other side of "which no ore is discovered. The life of the mine "depends upon rediscovering the ore, but in many "cases the vein is never found again. . . Every "man engaged in mining should be interested in fault "problems."

To facilitate the study of faults, the author points out that a consistent record of all data pertaining to the ore body should be kept. The typical problems discussed in the book are selected from those given in the laboratory courses in structural geology at the School of Mines of the University of Arizona.

In Section II. the nomenclature of fault movement is outlined. Instead of "vertical," the term "normal" is used. In the measurements of fault movements, displacements, separations, throws, and heaves are illustrated diagrammatically. There follow sections on methods of projection, line and plane intersections, and several on fault movements.

The reader will find it necessary to furbish up his descriptive geometry before he can extract the meat from Mr. Tolman's work. This done, there is no question as to his deriving practical benefit.

PERSONAL AND GENERAL

Mr. F. M. Passow, assistant superintendent of the Eustis mine, Quebec, passed through Toronto on November 21st on his way to Gowganda and Porcupine.

Mr. G. W. Rayner has returned from Northern Quebec, where he spent the summer prospecting. Mr. Rayner covered the Keekeek country, and the districts tributary to the Bell and Harricanaw rivers. During his travels Mr. Rayner met only two or three prospectors.

Mr. Frank C. Greene, a well-known coal mining engineer, is now general manager for the Graham Island (B. C.) Coal and Timber Syndicate, Limited, which holds coal lands situated on Graham Island, of the Queen Charlotte group, British Columbia.

Mr. Frank E. Elmore, of London, England, has been spending several weeks in British Columbia in connection with the experimental application of the Elmore Vacuum Process of concentration to the recovery of metals from local ores. Experiments are in progress at one place on mill middlings from lead-zinc ore and in another on low-grade copper ore.

Mr. Robert H. Stewart, general manager of the Consolidated Mining and Smelting Company of Canada, Limited, returned to his headquarters at Trail, B.C., early last month, after having spent a month in Ontario and eastern Canada.

Mr. H. H. Claudet, formerly of Rossland, B.C., who has been supervising experiments with one unit of the Elmore Vacuum Process plant on ore from the Hewitt-Lorna Doone mines, near Silverton, Slocan Lake district, is now superintendent of the Wakefield concentrating mill at which the experiments have been made for the Silverton Mines, Ltd., of London, England.

Mr. Elias Rogers, of Toronto, gave evidence last month before the British Columbia Tax Commission, then sitting in Victoria, B.C. In the course of his evidence Mr. Rogers urged the removal of the existing provincial tax of 15 cents per ton on coke.

Mr. J. A. McPhee, a graduate in mining engineering from the University of Washington, Seattle, State of Washington, is now engineer and surveyor at the Rambler-Cariboo mine, in McGuigan Basin, Slocan, B.C.

Mr. W. S. Rugh, for years in charge of the Le Roi Mining Company's office in Rossland, B.C., was last month the recipient of a valedictory address and souvenir presentation on the occasion of his leaving that town to reside on the coast.

The New Minister of Mines for Ontario.

Hon. W. H. Hearst

The Hon. William Howard Hearst, K.C., who succeeds the Hon. Frank Cochrane as Minister of Mines for Ontario, is a barrister-at-law. He was born on February 15, 1864, in Township Arran, County Bruce, Ontario. His early education was received at public schools and the Collingwood Collegiate Institute.

In the year 1891, Mr. Hearst married Isabella Jane Dunkin. His family consists of two sons and two daughters.

For years Mr. Hearst has been a leading Conservative worker in Northern Ontario. On the formation of the Whitney Government he was appointed Government agent in connection with the Lake Superior Corporation loan. This position he filled until April, 1908, when he resigned to contest the Sault riding.

It is gratifying to know that the Hon. Mr. Hearst has paid especial attention to mining law and to the mining industry generally. His experience in mining litigation has been varied and extensive.

The new Minister has always been an ardent champion of Northern Ontario. He is well fitted to carry on a constructive campaign of development.

In religion the Hon. Mr. Hearst is a Methodist. He has always been identified with philanthropic movements in his community.

CALCITE VEINS.

Calcite veins, like quartz veins, have no essential connection with valuable ore deposits. Quartz and calcite are the commonest fillings of fissures, because these minerals are the ones most commonly deposited from circulating solutions. When these solutions contain valuable minerals as well, the resulting deposit is very large compared with the cases in which it contains workable ore deposits. In the Waitekauri mine in New Zealand there was a large calcite vein of good value, but when the calcite vein junctioned with the quartz both veins lost their gold values, and no payable vein was again found.

In gas producer practice the fuel bed should not be operated at a temperature higher than 1,300 degrees C. High temperatures induce clinkering and in other respects lower the efficiency of the producer.

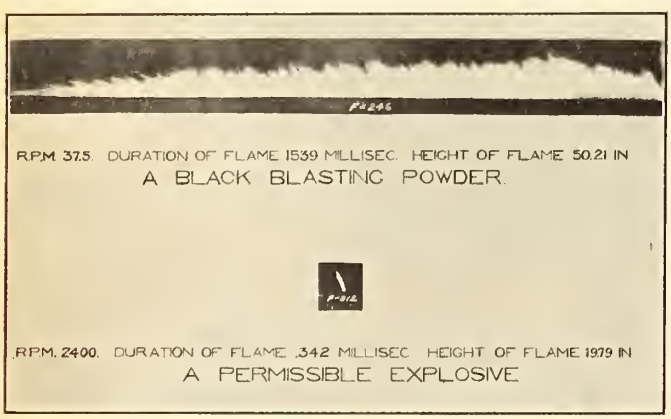
An Account of the National Mine Safety Demonstration, held in Pittsburg, October, 30th and 31st, 1911

(Editorial Correspondenee.)

At the invitation of the Director of the United States Bureau of Mines the Canadian Mining Journal sent a representative to witness the First National Safety Demonstration held in Pittsburg on October 30th and 31st.

The whole city was "en fete," not on account of the Demonstration, but because the last day of October had been chosen as the date on which to celebrate the centennial of steam-navigation on the Monongahela and Allegheny rivers. This, fortunately, made it possible for President Taft to honour both the Demonstration and the Centennial.

Proceedings began at 9 a.m., on Monday, at the Bureau of Mines buildings in the Arsenal grounds, 40th and Butler Streets. Addresses of welcome, brief and to the point, were delivered by the Hon. Walter L. Fisher, Secretary of the Interior, Dr. J. A. Holmes, Director of the Bureau; and Governor John K. Tener. The Hon. Mr. Fisher referred to the notable work of the Bureau and promised to see to it that new buildings and equipment be furnished. Governor Tener, a fine specimen of manhood, spoke for the State of Pennsylvania. Dr. Holmes proffered a general welcome.



R.P.M. 37.5. DURATION OF FLAME 1539 MILLISEC. HEIGHT OF FLAME 50.21 IN
A BLACK BLASTING POWDER.
R.P.M. 2400. DURATION OF FLAME .342 MILLISEC. HEIGHT OF FLAME 1979 IN
A PERMISSIBLE EXPLOSIVE

The morning audience, numbering perhaps 4,000, was made up of miners, operators, foremen, officials, and delegates from other States. Canada sent half-a-dozen or more representatives.

Continuous demonstrations were shown in the chemical and physieal laboratories, in the boiler room, the fuel laboratory, the petroleum laboratory, the gas laboratory, and the explosives laboratory. The experiments included the sampling of gas, the breaking of incandescent lamps in an explosive mixture of gas and air, the smokeless combustion of low-grade, high-volatile fuel using mechanical stokers, the exhibition of apparatus for testing explosives, the briquetting of various fuels, the ignition of coal dust, and many other incidental tests. The gallery explosion of coal dust, using first a permissible explosive and then black powder was the feature of the morning. The ballistic pendulum, a device adapted from an antiquated piece of ordnance, was spectacular. Several rescue and Red Cross cars were on a siding and were examined by the visitors. The crowd, separated into several continuous streams, moved continuously through each building and section. The marked courtesy and the unfailing patienee of Dr. Holmes and his staff made it possible for nearly all of us to get a complete view of the buildings and apparatus.

At 2 p.m. on Monday the whole concourse was taken out to the Experimental Mine at Bruceton, about 12 miles outside of Pittsburgh. Here the mine, whieh consists of two specially constructed converging tunnels, had been prepared for a large-scale explosion. One pound of coal dust per linear foot had been distributed on scantlings. Electric connections were laid, and after the crowd had walked through the mine, the lights were removed, and the first eharge of permissible was fired. No coal dust explosion followed. Owing to a defect in the connections, the second experiment, in which black powder was employed, was not brought off until 5.45 p.m. Rain was falling and daylight had failed. Most of the crowd had moved down to the railway traek about 400 yards from the entries. Even there the detonation that followed was almost overpowering. Vast tongues of flame issued from both portals. No more vivid and appalling illustration of what a mine explosion means could be imagined. Words cannot convey the magnitude, force, and magnifieence of the phenomenon—therefore more words shall not be employed. It suffices to say that all of us were impressed beyond possible expectations.

To give a clearer idea of the plan of the mine I append here a few notes from the official programme:—

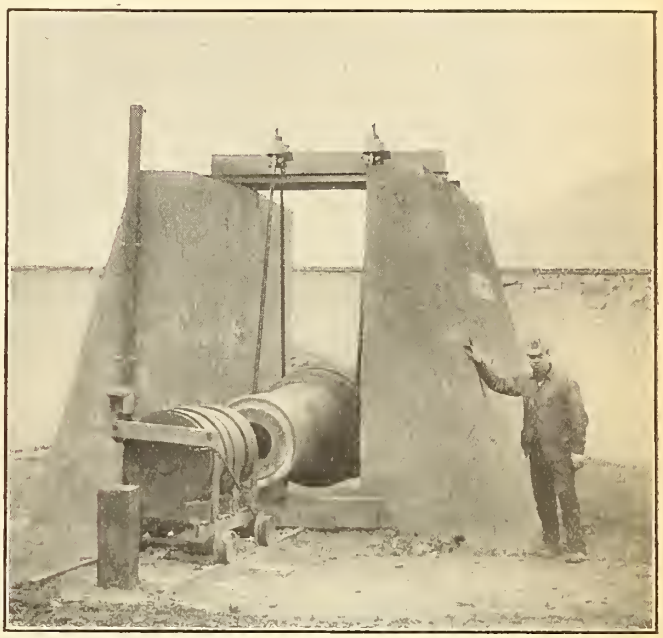
"The Experimental Mine of the Bureau of Mines is situated near Bruceton, Pa., on the Wheeling branch of the Baltimore & Ohio Railroad and is in the Pittsburgh seam, which at this point outcrops on the side of a hill about one hundred feet above the railroad.

"Object—The mine was opened primarily in order to study the phenomena of dust and gas explosions and to test various methods of preventing and checking explosions in progress under actual mine conditions, which requires repeated explosions under varied conditions.

"Plan.—The arrangement of the part of the mine which will be used for the explosion of Oetober 30th is indicated on the map shown on opposite page. An outside steel gallery is of one-half inch boiler plate, 102 feet long and 6 feet 4 inches in diameter, is connected by a 20-foot movable steel section and a 20-foot concrete explosion-door section to a slant entry. This entry intersects the east entry or aircourse 192 feet from the end of the explosion door section. The entire slant entry, 70 feet of the aircourse, and 169 feet of the main entry are lined with reinforced concrete. Heavily reinforced concrete portals are built at the mouths of the gallery slant and main entry.

"Explosion Data.—One surface and four underground instrument chambers have now been constructed. The wires from the instruments in these stations pass through pipes behind the concrete lining to recording instruments in the observatory. Pressure var-

Apparatus for photographing the length of flame of an explosive.



Ballistic Pendulum

iations at the stations and velocity readings are taken by these instruments in conjunction with those at the observatory. Gas samples are taken by special devices at the instrument station.

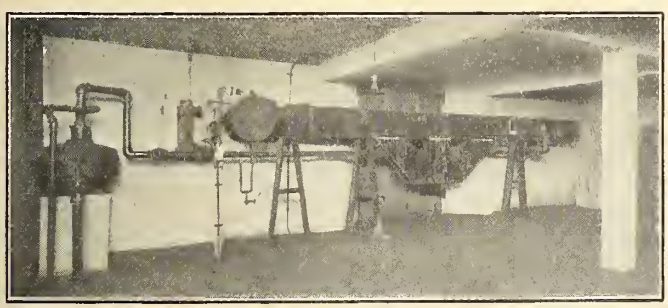
"Explosion Conditions.—The mine is prepared for the explosions by placing coal dust on the floor of the steel gallery and on wooden shelves along the sides of the entries, which is exploded by firing a charge of black blasting powder (representing a blown-out shot) into the steel gallery.

"Gas Samples.—Afterwards the entry doors are closed and men in oxygen helmets enter the mine through a slide door in the main entry door, to take gas samples, extinguish incipient fires and inspect the condition of the roof. Later, when conditions are safe, the fan is started and the mine cleared of afterdamp. Should it be necessary, timbermen then enter the mine to remove loose pieces of hanging rock and place temporary timbers. Afterwards records are made of the effects of the explosion.

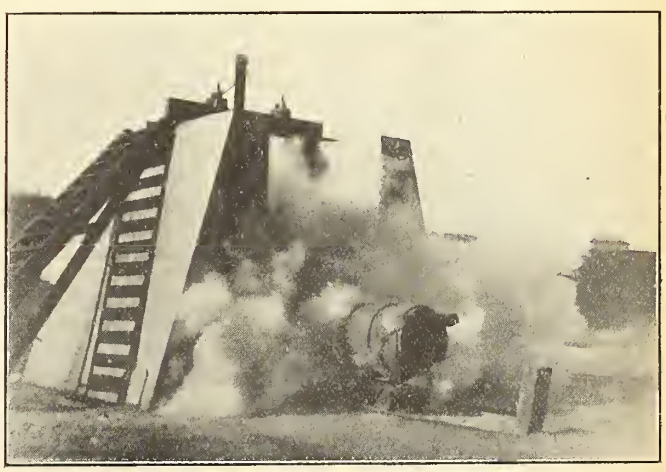
"Inspection.—On October 30th experienced mining men among the visitors will be permitted to inspect the mine before and after the explosion, when it has been put in good condition."

At sharp 9 o'clock on Tuesday morning a large crowd began to pour into Forbes Field, a baseball park opposite the Hotel Schenley. The capacious 3-storey steel grandstand was fairly filled. At the opposite side of the field was placed a large steel explosion gallery, from which battery wires were strung to the President's box in the stand. From 9 o'clock until 10.30 o'clock the time was occupied with exhibition and competitive tests between 40 First-aid squads of six men each. Ten "problems," covering burns, wounds, gas poisonoing, and electric shock were performed. Each team carried its own equipment. Coal companies from all over the United States were represented. The men were all miners, specially trained and chosen by local elimination trials.

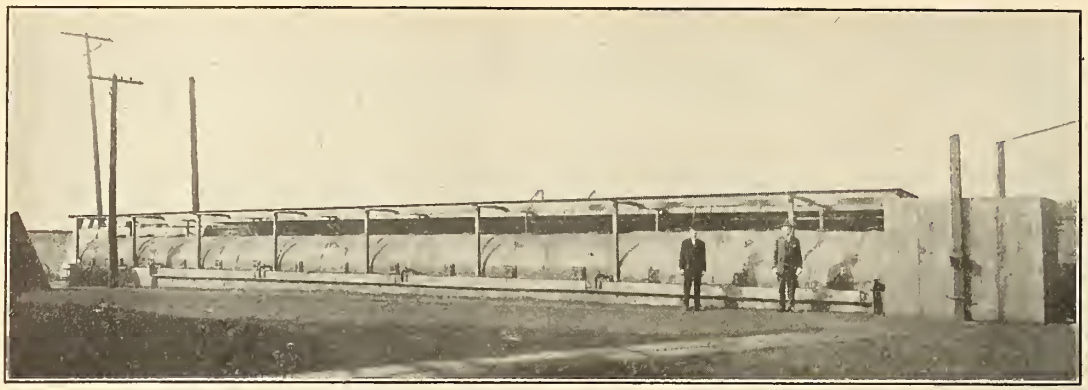
At 10.40 a.m., one-half pound of 40 per cent. nitroglycerine, tamped with one pound of dry fire clay, was fired into the steel gallery. Only a dull concussion was heard, and no explosion of dust resulted. Twenty minutes later, a corresponding charge of FFF black powder, tamped with dry fire clay, was fired. The 150 pounds of coal dust that had been distributed through the gallery exploded with deafening effect. A flame many feet in length shot from the gallery mouth.



Gallery for testing safety lamps in the presence of gas.



Ballistic Pendulum in action.



Steel Gallery in which Coal Dust experiments are made.

An explosion of coal dust in the steel gallery.

A few minutes later, while volumes of dense brown fumes were still billowing from the gallery, a rescue party, equipped with various types of breathing apparatus, entered the gallery and effected the rescue of two dummies. Several squads of reseuers then performed a series of evolutions before the President.

One interesting experiment was conducted earlier in the morning. Mr. G. A. Burrell, an officer of the Bureau, entered a glass box, the atmosphere of which contained 0.25 per cent. of carbon monoxide (white damp). He took with him three eanaries. While the gas had no effeet upon the experimenter, all three of the birds began at once to show signs of distress. After a few minutes they collapsed. Mr. Burrell stayed in the box for some minutes further. Later the birds were all revived by the application of oxygen.

At 11.30 a.m., President Taft presented the trophies. Speeches were made by Governor Tener, Hon. Mr. Fisher, and Miss Mabel Boardman. Miss Boardman represented the American Red Cross Soeiety.

To the visitor it was a slight shock to hear Governor Tener declare that all the anthracite coal in the world came from Pennsylvania. Similarly it was a souree of surprise when the Secretary of the Interior asserted that the United States led the world in mine safety work. This is so beside the mark as to need no comment.

* * * *

Too much praise eannot be bestowed on Direetor Holmes and his efficient lieutenants Messrs. Paul, Shields, Hall, Feehan, and Clement. The limited time at their disposal made it obligatory to crowd into one day and a half, events that could easily have been spread over a week. It was necessary, also, for the sake of impressing gatherings that numbered from two thousand to fifteen thousand, to make the demonstration spectacular. And it was speetacular. The whole effeet was impressive, educative, and inspiring.

The JOURNAL hopes that when our own Mines Branch Testing Station is eompleted some such public exhibition can be arranged.

First Aid to the injured—bandaging for injury to jaw.

Interior rescue room Bureau of Mines Station.

On the Mica Deposits of Ontario and Quebec.

Hugh S. de Schmid, M.E.*

The summer season of 1910 was devoted to an examination of the principal mica regions of Ontario and Quebec; with the object of gathering material for a revised edition of the monograph on mica, issued by the Mines Branch in 1905.

While the chief purpose of the tour was to examine and report upon the mica deposits at present being worked, time was also devoted to an examination of old mines, with the object of collecting geological data bearing on the origin of the mica, and of compiling as complete a map as possible of the localities in which the mineral has been found to exist in commercial quantities. While it was found impracticable to visit every small surface pit from which mica has, in the past, been taken, all available information regarding such was collected, and will be embodied in the full report.

Quebec.

Since the original monograph was published in 1905, new amber mica occurrences have been located and worked in Quebec, north of the districts covered by Mr. Cirkel's report, and it would appear that the mica-bearing region extends considerably north even of the area which had already been prospected.

In the Lievre River district, the most northerly workings are situated a few miles from Notre Dame de Laus, in the township of Bigelow, where Mr. W. Parker, of Buckingham, has carried on considerable surface work, and discovered extensive deposits of mica on range V, lot 52. The mica is a rather dark amber, and of only medium splitting quality.

In the Gatineau region the mineral has been mined as far north as range II, lot 28, of the township of Egan, where Mr. Joanis, of Maniwaki, has taken out several thousand dollars worth of fair amber mica.

Prospectors were met with in the vicinity of Pemichangau Lake, who reported favourable indications on ranges V. and VII. of the township of Blake.

The most westerly mica deposits which have as yet been worked in the area under consideration are situated in Litchfield and Huddersfield townships, where Messrs. Bowling Bros., of Thornby, and the Calumet Mica Co., of Bryson, have carried on some surface work.

It may be remarked that the mica bearing dykes (pyroxenites) are to be found cutting the Laurentian rocks throughout almost the entire district situated immediately north of Ottawa and the Ottawa River, and over an area of which the boundaries to the north, east, and west are as yet but poorly defined. The presence of these pyroxenite dykes, while indicative always of a possible occurrence of mica, does not necessarily imply the existence of a commercially valuable deposit. In some districts mica in quantity is to be found in pockets throughout the entire mass of such a dyke, while in others but scanty traces of the mineral are to be met with, though the rock, to all appearances, is identical in both places.

Owing to its occurrence in such sporadic fashion, mica is among the most uncertain, and, from a miner's point of view, one of the most disappointing of minerals to follow. Often when the indications of a continuance in depth of the deposit are most favourable, the fissures narrow down, and all traces of the mica are lost; on the other hand, seemingly barren rock will suddenly yield large quantities of high-grade crystals, which, however, may form only an isolated group, and be underlain by many feet of rock before mica is again met.

While it is not intended to assert that mica in quantity exists on every lot in the region between the Lievre and Gatineau rivers, the district is nevertheless so extensively traversed by pyroxenite dykes exhibiting traces of the mineral that the possible existence of deposits on almost any lot cannot be said to be precluded.

In addition to the localities mentioned, mica also occurs farther to the east, in Argenteuil county, Wentworth township, where several operators have mined on a small scale. The mica in the last-named district, as in the Saguenay region, Berthier County, still farther to the west, is chiefly of the muscovite variety.

Ontario.

The mica-mining region of Ontario has not been extended by any new discoveries of importance since the publication of the last report.

The chief centres of mining activity are Sydenham and Micaville, in the townships of Loughborough and North Burgess, respectively. In the former district, the General Electric Company's mine — the old Smith and Lacey — still remains the chief producer, and employs an average staff of 35 men. The output and reserves of this mine play an important role in fixing the market price of the mineral, and the General Electric Company, which carries on its mining operations under the name of the Loughborough Mining Company, can be said to practically control the market.

The above company also owns various other mines in different parts of the country, chief among which are the Cantin mine, on lot 1, range IV., of South Burgess township; the Hanlon mine, on lot 11, range VI., of North Burgess; and the Chaibec mine, on lot 7, range A, of the township of Wright (Quebec). None of the latter mines were working when visited.

The occurrence of a yellowish, and rather brittle mica, whose composition and exact species have not yet been determined, in a highly metamorphosed rock in the Sydenham district, may be mentioned here as constituting a type of mica deposit in many respects dissimilar to the majority of occurrences visited. The deposit in question is at present being worked by Mr. J. Richardson, of Kingston, with an average staff of half a dozen men, and is situated on lot 1, range X., of the township of Loughborough.

The intrusive rock to which the mica probably owes its origin had not, at the time of my visit, been met with—the depth reached by the workings not exceeding 60 feet. The mica appears to have been deposited by pneumatolytic emanations from the igneous intrusion of some basic rock which did not reach the surface, but which will probably be met with at an inconsiderable depth.

Three beds, from 1 to 2 feet thick, of a reddish quartzite, are met with in the workings. These layers

*Abstract from Summary Report of the Mines Branch, Ottawa.

contain no mica, and the rock in their immediate proximity is also practically devoid of the mineral.

The source of the mica is, in all probability, a basic laccolite.

A similar mica is also found on lot 5, range II., of Bedford township, this occurrence being almost identical with the foregoing. In this case, however, the country rock is limestone, belonging to the Archæan formation, and is of the normal white, coarsely crystalline type.

The association with the mica of secondary minerals such as vesuvianite, actinolite, garnet, etc., at both the above-mentioned mines, is interesting, and will be further described in the full report.

Qualities of Mica.

With the exception of some half dozen, all the mines and prospects visited, numbering over 200, were concerned with phlogopite, or amber mica deposits. The colour of the mica was found to range from almost black, in which case the resemblance to biotite was very close, to almost colourless; the very dark and the very light-coloured varieties being, as a rule, the poorest splitters.

The suitability of mica for electrical purposes depends essentially on two factors: (1) its degree of cleavage, and (2) its non-conducting properties. Consumers of the mineral seem to vary in their opinions, some preferring a relatively dark mica of medium splitting quality, while others refuse to take any but the light-coloured variety — on account of its apparent freedom from iron — though its cleavage may be much inferior to that of the dark-coloured.

Brittleness also is an important consideration with consumers, this being a fault which affects both the dark and the light micas.

With the advent, however, of mica-board manufacturing, brittleness has ceased to prove such a detrimental factor, since even the most brittle mica is sufficiently flexible in very thin layers (½ to 1 mil.) to be used in the building up of mica plate.

Some manufacturers use both dark and light amber mica, and mix in a certain proportion of Indian white mica (muscovite) the resulting plate possessing, it is claimed, all the qualities necessary to the manufacture of electrical appliances.

Status of the Mica Industry.

The condition of the mica market, though inclined to show a slightly better tendency, towards the latter part of 1910, has not conduced to any great activity on the part of operators during the past few years. Some few of the larger owners are continuing to work, but practically all the smaller mines are idle.

A peculiar feature is, that while in the Quebec mica districts mining was declared to be unprofitable under present mining conditions, operators in Ontario, while admitting that prices were low, yet contrived to find a satisfactory enough market to enable them to continue working their properties, and even to consider the reopening of mines which have been idle for some years. The cause of this divergence of opinion is difficult to arrive at, since wages and general mining expenses are, if anything, lower in Quebec than in Ontario.

Owing to this inactivity amongst mica-miners, fully 80 per cent. of the mines visited were found to be idle, and the pits more or less full of water, and consequently inaccessible.

Although in the past, Canadian producers have, for the most part, seemed to be content with the market provided by the United States, shipments are now being made in increasing quantity to English consumers, and inquiries were often made during the past season as to names and addresses of buyers in the United Kingdom.

While appreciating the superiority of Canadian amber mica for electrical purposes, English and Continental manufacturers nevertheless still procure the greater part of the mica they require from India.

Subjoined are tables showing the amount of mica imported into the United Kingdom during the past five years from Canada and India respectively, and also the imports of Canadian mica into the United States for the same period.

TABLE 1.

Exports of Mica from Canada to Great Britain.*

Calendar Year.	Tons.	Value.	Average Value per ton.
1905	179	$25,717	$143.07
1906	167	58,735	351.71
1907	80	43,913	548.91
1908	156	81,050	519.55
1909	30	24,316	810.53

*Compiled from Mines Branch statistics.

TABLE 2.

Imports of Mica into Great Britain from Canada.*

Calendar Year.	Tons.	Value.	Average Value per ton.
1905	130	$24,349	$187.30
1906	209	51,618	246.98
1907	88	51,497	585.19
1908	122	74,362	609.52
1909	34	30,749	904.38

*Compiled from British Board of Trade Returns, 1910.

TABLE 3.

Imports of Mica into the United Kingdom from India.*

Calendar Year.	Tons.	Value.	Average Value per ton.
1905	901	$369,506	$384.50
1906	1,845	782,397	423.15

*Compiled from British Board of Trade Returns, 1910.

TABLE 4.

Imports of Mica into the United States from Canada.*

Calendar Year.	Tons.	Value.	Average Value per Ton.
1905	253	$121,560	$480.47
1906	539	328,991	610.35
1907	767	596,321	777.47
1908	172	140,166	814.92
1909	107	132,941	796.05

*The Foreign Commerce and Navigation of the United States.

It will be seen that in 1905—the year in which the greatest quantity of mica during the quinquennial period in question was shipped from Canada to English consumers—this quantity was exceeded by the Indian shipments by more than five times; while in 1909,

the Canadian mica imports were only one forty-third of the Indian.

A comparison of Tables 2 and 4, showing the average value per ton of the mica shipped to the United States and of that sent to English buyers, discloses a rather remarkable difference of price; in one case (1905) the latter would appear to have paid $336.80 per ton more for their mica than the Americans, while in 1909 the reverse is the case, the prices being in favour of the English consumers by $14.48 per ton.

The accurate average price is not, however, claimed to be shown in the above tables; in fact, the figures given in the British Board of Trade returns, show discrepshown in the above tables; in fact the figures given ments published by Canadian shippers amounting in one year (1906) to as much as $104.73; the average price per ton, calculated from the British Board of Trade returns, being $246.98; while the figure arrived at from the statements furnished to the Mines Branch statistical department was $351.71.

A comparison of the figures given in Tables 1 and 2 will show how greatly these two sources of information vary in their statements both as regards tonnage and value.

The cause of the wide difference in value of the English and American shipments, given in the two tables —differences which render any sort of comparison futile—is probably to be found in the various grades of mica shipped to the different countries.

Shippers, being bound by no compulsory system of classification or grading other than may be agreed upon between themselves and the buyers, may, in one instance, forward a consignment of more or less roughly trimmed mica of comparatively low unit value, while to another purchaser only high-grade sheets are sent, the difference in value of equal weight shipments being accordingly very great, while both consignments would be similarly classed in the Trade Returns as "mica," without distinction as to quality.

It is worthy of remark that, while the yearly average unit value of the Indian mica imported into the United Kingdom in the five years shows a maximum variation of $119.44, that of the Canadian mica similarly imported reaches the high figure of $691.97 (mean value calculated from Tables 1 and 2).

The comparatively small difference in the case of the Indian mica is doubtless due to the standard quality of the mineral, which varies little in colour and general character (elasticity, brittleness, etc.) whereas the amber mica possesses all these attributes in greatly varying degree—its price varying accordingly.

It is due to the fact that the Indian mica can always be depended upon to be of the same standard quality, that buyers in the United Kingdom have generally preferred this variety to the amber, which can seldom be relied upon, even in a single shipment, to be of uniform grade and colour.

Canadian producers, while realizing this, yet appear reluctant to fall in with the wishes of the English market, and cannot agree to the request of prospective purchasers in the United Kingdom to furnish shipments which are uniform in quality with samples submitted by them.

There can be no doubt that, could a satisfactory system of sorting be devised and agreed upon amongst mica dealers, the market relations and conditions between Canada and Great Britain would be materially improved.

For the purpose of further emphasizing the discrepancy between tables calculated from returns furnished by shippers on the one hand and by Foreign Trade returns on the other, an additional table (5), of exports of Canadian mica to the United States, is given: the figures here given are taken from "Trade and Navigation."

TABLE 5.

Exports of Mica from Canada to the United States.*

Calendar Year.	Tons.	Value	Average Value per Ton.
1905	351	$150,767	$429.62
1906	735	519,479	706.77
1907	468	372,798	796.58
1908	132	115,005	871.25
1909	325	229,689	706.74

*Trade and Navigation.

The following table (6) gives the total annual production of mica in Canada for the same period:—

TABLE 6.

Total Annual Production of Mica in Canada.*

Calendar Year.	Tons.	Value.
1905	...	$178,235
1906	574	303,913
1907	774	312,599
1908	436	139,871
1909	369	147,782

*Mines Branch returns.

The fact that, in some cases, the total annual production falls short of the combined exports to Great Britain and to the United States for the year, is due to the practice made by some producers of accumulating large stocks of mica: these reserves, in many cases, remain on the mine, and so do not figure in the production returns.

*At the present time, large quantities of mica are being held in reserve, which owners are not disposed to ship at current prices.

---

*Editorial Note:—Since this report was written the market has become much stronger. It is now decidedly active.

TREATMENT OF ELECTROLYTIC MUD.

The mud is washed free from sulphate of copper, slowly dried in steel trays and then heated to a dull red to get rid of the tallow and alter the mechanical conditions of the graphite with which the starting sheets were originally coated. Before the practice of heating the mud was adopted in electrolytic refining in Australia, says Mr. G. H. Blackmore, it was found impossible to get the copper out of the mud except after days of boiling with sulphuric acid, and even then as much as 40 per cent. of it remained in the residue.

QUARTZ IN TUBE MILLS.

Quartz from the mine is now largely used in tube mills. It is an effective grinder, but does not make a good lining. In feeding a mixture of quartz and pebbles, the pebbles make up the lining, whilst the quartz stays in the charge, so that the advantages of both materials are gained.

An Address on the Past, Present and Future of Copper

Delivered before the American Mining Congress, Chicago, on Wednesday, Oct. 25, 1911, by Horace J. Stevens

The Past.

The great copper industry of the present day is a thing of small beginnings. One century ago, in the year 1811, the world's production of copper was a trifle under 10,000 long tons, an amount smaller than was secured last year by any one of more than twenty different mines. During the present year the great Anaconda mine, of Butte, has produced, during nearly every month, as much copper as was supplied by all the mines of the world, in the entire year of 1811.

Fifty years ago, in 1861, the world's output of copper was but a trifle more than 100,000,000 pounds, a production that was exceeded, in 1910, by the Anaconda, American Smelters Securities Co., and Phelps, Dodge & Co. The production of the year 1900, the last of the nineteenth century, was just fifty times as great as that of the year 1800. Should the same ratio of increase be maintained during the twentieth century, the output of the year A. D. 2000 would be 24,318,150 long tons of copper, twenty-five times as much as the present production, and even a fifty-fold increase for the twentieth century would allow an average increase of less than four per cent., while the average annual increase, for the decade beginning 1900 and ending 1910, was almost exactly seven per cent., compounded yearly. Those who foresee a complete collapse in the copper industry would do well to give consideration to the actual figures of increase during the past. The copper industry does not move forward at even an approximately steady rate from year to year, but is given to advancing by great leaps, almost inevitably followed by periods of quiescence, or even of actual retrogression. High prices for the metal stimulate production, while curtailing consumption, and, as a direct consequence, output is increased, which decreases prices, which in turn brings about decreased production, due to the inability of small and weak producers to stand the strain of low prices. Decreased production again brings about high prices, and the cycle is begun anew. Much the same conditions existed in the American iron and steel industry for 50 years, until the formation of the United States Steel Corporation, which, while unable to prevent periods of depression, as its sponsors fondly hoped, has proven a wonderfully steadying factor in the iron and steel market, serving the purpose of a gigantic balance-wheel.

Growth.

The growth of the copper industry is best shown by the following figures of the world's production, by decades, in long tons: 91,000 tons in the decade ending 1810; 96,000 tons in 1820; 135,000 tons in 1830; 218,000 tons in 1840; 291,000 tons in 1850; 507,000 tons in 1860; 900,000 tons in 1870; 1,189,000 tons in 1880; 2,373,000 tons in 1890; 3,708,000 tons in 1900; 7,390,000 tons in 1910. The influence of the electrical industry upon the consumption of copper is plainly shown by the figures since 1880. The production of the seventh decade of the nineteenth century was only 900,000 long tons, or a trifle less than ten times the output of the first decade of the century, while the production of the last decade of the century, ending 1900, was more than forty times the output of the first decade, and was more than four times as great as that of the decade ending in 1870, only thirty years before. The output of the decade ending 1910 was more than six times as great as the output of the decade ending in 1880, and was almost exactly double the production of the previous decade ending in 1900. The production of copper by the world, amounting to approximately 7,390,000 long tons, for the decade ending 1910, amounted to more than three-fourths of the total world's production of copper for the entire preceding century.

Figures of production and consumption of any given commodity in universal use may differ from year to year, according to whether a surplus is accumulated, or a preceding surplus is drawn upon, but over long-term periods, production and consumption necessarily are the same, and, figured by decades, it is safe to say that the figures of production are practically the figures of consumption. At present there is a copper surplus, of which much is heard, but to show how comparatively unimportant the present surplus is, when compared with the figures of output for the preceding decade, it may be stated that the world's surplus of copper at the present time is slightly less than 300,000,000 pounds of finished metal, or a trifle under 135,000 long tons, an amount less than 5½ per cent. of the total production of the decade, and equivalent to only about eight weeks' supply of copper, at the present time measuring the supply either by productive capacity or by consumptive demand.

Very exact figures are available regarding production, dividends, costs and metal prices of the mines of the Lake Superior district since the first production was secured, in the year 1845, the total output for that year having been only 24,880 pounds of finished copper. The total production of fine copper by Lake Superior mines from 1845 to 1910, inclusive, a period of sixty-six years, or two-thirds of a century, was 5,122,478,402 pounds, having a gross value of $726,849,840, from which were paid dividends of $182,824,770, the ratio of dividends to gross values for this entire period amounting to 25.1 per cent., and dividends, divided by copper production, show average dividend payments of 3.56 cents per pound. The average price received from all Lake Superior copper for this period of sixty-six years was 14.19 cents per pound, which, after deduction of dividends, leaves an estimated cost of 10.63 cents per pound for all years. By adding the figures of expenditures on unproductive mines, amounting to about $60,000,000, the cost of Lake Superior copper would be made almost 11½ cents per pound, and by adding a further $15,000,000 for assessments on mines that have since repaid in dividends the original assessments, the cost of copper would be made about 11.85 cents per pound, leaving a net margin of profit for the entire production of almost exactly two

cents per pound, plus the present aggregate value of the various active mines.

Omitting the production of mines that have not proven profitable, the average cost of Lake Superior copper, yielded by dividend-paying mines, has averaged about 9.5 cents per pound for all years, and the present cost of making copper by all of the producing Lake Superior mines probably is slightly above nine cents per pound. The actual cost of making copper in the leading producing fields probably is between nine and ten cents per pound at the present time. Some of the newer fields, which are skimming their cream, show lower costs, but it is difficult to see where the world will be able to produce its copper in years to come at an average cost materially under ten cents per pound, this figure excluding the limited production of badly planned and badly managed mines, which yield only a small fraction of the total copper output, but secure their metal at an average cost very much higher than the average cost of all mines.

For the immediate future, the supply of copper in sight is fully adequate, and no unduly high prices need be anticipated, but the figures clearly foreshadow another boom period, within the next two to four years, at which time the alarmists will be as badly scared, for fear that the copper supply is petering out, as they now are for fear that the production is so much greater than consumption that nothing but permanent disaster is in sight. Allowing an average increase of consumption of 7 per cent. yearly, the figure that has ruled during the first nine years of the present century, the world's requirements of copper will amount to approximately 1,650,000 long tons in 1920; 2,975,000 long tons in 1930, and 5,350,000 long tons in 1940—the latter named year, now only 29 years ahead, calling for a copper output almost six times that of the present rate. Twenty-nine years ago, or in the year 1882, the world's production of copper was 181,622 tons, or about one-fifth of the present output. Allowing for even a five-fold expansion during the next three decades to correspond with the five-fold expansion in the three decades past, the world's copper requirements in 1840 will be more than 4,500,000 long tons. Should the ratio of increased production and consumption remain at an average of seven per cent. for the balance of this century, the world would yield and consume in the year A. D. 2000, about 175,000,000 long tons of copper, a quantity of the red metal more than double the tonnage of the world's present production of iron and steel.

THE FIRST DECADE OF THE TWENTIETH CENTURY.

A survey of the progress made by the copper industry during the first decade of the twentieth century, now lacking only a few weeks of completion, shows no revolutionary changes, but does show steady and in some cases phenomenal progress, in nearly every division of the industry. In the matter of mines, the old districts of Butte and Lake Superior remain the largest producers, but Arizona, with a half-dozen important copper fields, passed Montana in output in 1908, though again taking second place in 1909. In copper mining, the most important development of the decade has been the making of the so-called porphyry mines, in which disseminated copper sulphides are mined from schistose or porphyritic country rocks. The development of such important new producers as the Utah Copper, Nevada Consolidated, Miami and others of this class, has alarmed many people, who jump to the conclusion that the so-called porphyry mines must close down the older mines, developed on veins in Butte and other camps, and on the stratified trap beds of Lake Superior. There is no real occasion for this alarm, as the porphyry mines, while highly important, are not apt to be developed in large numbers. In fact, the entire western part of the United States has been scoured, by the keenest and strongest aggregations of capital in the copper business, for promising country-rock deposits, with a net result to date rather insignificant in the number of properties developed, though highly important in output secured already, and even more important in promise for future production. When the Mesaba iron range was opened, eighteen years ago, a similar wave of pessimism swept over the mine-owners of the older iron ranges in Michigan and Wisconsin, but time has proven that the high-grade ores of the Mesaba, capable of being mined by steam-shovel, at wonderfully low costs, are absolutely necessary in furnishing an adequate supply of ore to the iron and steel works of this country, and similarly it will be found, as time passes, that the production of the porphyry mines is absolutely essential in supplying the copper needed by the world at anything like a fair figure to the consumer. Processes of actual ore extraction have been modified and improved in many fields, with a resultant increase in safety to miners and decrease in cost of ore extraction. The steam-shovel has come to stay in copper mining.

Strange to say, copper mines, which are vitally interested in extending the use of copper, were somewhat slow in adopting electric power, but rapid progress has been made in this direction during the past decade, and all of the mines of Butte are now electrified, while there has been a great increase in the use of electric energy in the Lake Superior district. The constantly increasing use of hydro-electric power is now restrained, and further restraints are threatened by the conservationists. The newly adopted system at the Anaconda mine, in Butte, which combines the utilization of hydraulic, electric and pneumatic power, offers great possibilities of pliancy and economy, and the lead of the Anaconda is likely to be followed by many other important mines.

In ore reduction, material progress has been made in concentration, the very general adoption of Wilfley tables and similar devices permitting the saving of fines previously wasted. Hydraulic classifiers, settling tanks and a variety of ingenious devices for the saving of the uttermost mineral values, have aided in this work, and are now found in most important mills. Slimes, previously wasted, are now carefully collected in slum-ponds and reworked; with an aggregate yearly extraction of many millions of pounds of copper formerly wasted.

Perhaps the most striking progress made during the past decade, in any division of the copper industry has been in smelting. No new principles have been adopted in either reverberatory or blast-furnace work, but reverberatories of a gigantic size hitherto unknown have been adopted at many plants, while even more striking progress has been made in the capacity of blast-furnaces. Ten years ago, a 300-ton blast-furnaee was considered exceptionally large, and near the possible maximum size, but the Washoe works of the Anaconda Copper Mining Co., again blazing the way, now have two furnaces, each 56 inches by 51 feet in size, with a maximum daily smelting capacity of 1,800 tons each, and a third furnace that is 56 inches wide and 87 feet long at the

tuyeres, this mammoth furnace actually having smelted 3,100 tons within 24 hours. It has been my privilege to see this great blast-furnace with smelting in progress at the western end, while the eastern end was frozen, and repairs in progress within the bosh.

The past decade has been a further extension of the electrolytic process of refining, and the great bulk of the world's copper now is refined by elcetrolysis. In fact, very little finished copper, other than electrolytic, reaches the market, except from the Lake Superior mines, the product of which commands a premium by reason of its extra toughness and superior adaptibility to drawing and stamping. With depth, many of the Lake Superior mines have shown a marked increase in arsenic, and for this reason a considerable part of the Lake Superior copper now is refined electrolytically, and sold as electrolytic and not as Lake copper.

Combines and Mergers.

At various times in the past efforts have been made at copper corners, but these have proven uniformly unsuccessful. The first copper corner was by the Associated Smelters, of Swansea, and might be termed the original copper trust. The Associated Smelters, which flourished from 1840 to 1860, were arbitrary in their operations, buying cheaply, selling dearly, and zealously guarding their smelting processes. As a result of the very short-sighted policy of screwing prices of ore and matte to the lowest possible figures, while selling the finished product at the highest possible prices, with the ore producers aggravated by arbitrary charges for draftage and moisture, and the further grievance of unfair assay methods, the mine-owners were led to build independent smelters at and near the mines, in most of the principal copper-producing districts, these effectually destroying the power of the Associated Smelters of Swansea as the arbiter of the copper industry.

The second attempt at a copper corner was made by the Société des Metaux, of Paris, under the leadership of M. Secretan, the Société des Metaux becoming, in February, 1887, one of the sixteen underwriters that organized the Syndicat Secretan, with a nominal capitalization of $13,587,000. This syndicate contracted with the leading copper producers for their output, and speedily advanced the price of the metal to 17¾ cents, effecting an increase of more than 50 per cent. in price within one month. Consumption immediately declined to a low figure, and the Secretan Syndicate borrowed enormous sums to carry its rapidly accumulating copper from French, German, and English banking houses, the Comptoir d'Escompte of Paris alone lending the enormous sum of $33,368,000 to the Syndicat Secretan. This corner broke early in 1889, after about eighteen months' existence, and in a single day, in the spring of 1889, the price of copper dropped from £70 down to £35 per long ton. About four years were required to clean up the wreckage remaining from this ill-advised corner, and put the copper industry soundly on its feet again.

The third attempt at a copper corner was made in February, 1889, by the organization of the Amalgamated Copper Co., which corporation maintained the price of copper, arbitrarily, at 17 cents per pound, until October, 1901, when an accumulation of 200,000,000 pounds of metal compelled a break that took the price of copper down to about 12 cents per pound, and about three years were required by the industry to recover from the effects of this corner.

The price of 26¼ cents per pound, reached in March, 1907, by Lake copper, was not the result of any corner, but came about through an ill-advised scramble by consumers, who feared that they could not secure the metal. As a result of the high price, consumption was curtailed sharply, in all directions, as happens inevitably under such unsatisfactory price conditions, and the copper industry of the world still suffers from the existence of a surplus of slightly under 300,000,000 pounds of metal, remaining from a surplus that, including both visible and invisible supplies, reached about 450,000,000 pounds at the end of 1909, since which time there has been a small but steady decrease in surplus from month to month.

The tendency in copper mining, as in all other branches of industry, is toward combination in ever-larger units. This tendency is based upon and governed by purely economic laws, and the laws of political economy are so much stronger than any law ever devised by a parliament, or any ukase ever promulgated by a deposit, that it requires no spirit of propheey to foreeast the ultimate outeome of the present clash between the laws of political economy and the laws of congress.

In the copper industry the great bulk of production now is furnished by about a dozen different interests. The Amalgamated Copper Co. has a productive capacity of about 300,000,000 pounds yearly, with an actual output last year of 223,808,546 pounds. The American Smelting & Refining Co., or Guggenheim interests, have a productive capacity only slightly inferior to the Amalgamated, with an actual output of 174,150,000 pounds in 1910, which figure will be exceeded materially this year. The production of Phelps, Dodge & Co. was 116,888,070 pounds in 1910, while smelter production, including custom ores treated, was 138,805,562 pounds, and the sales agency of this firm handled 194,138,696 pounds of copper last year. The Calumet & Hcela, with its subsidiaries, has a productive capacity of nearly or quite 150,000,000 pounds yearly. The Rothschild interests, controlling the Rio-Tinto of Spain, and the Boléo of Mexico, have a eopper output of more than 100,000,000 pounds yearly.

The leading copper producers of the world are now operating under check, a 10 per cent. reduction in output having been put into effect in August of last year. Under the Sherman Anti-Trust law, this checking of production would be considered criminal, if it could be proven, yet the reduction of output was absolutely necessary in order to save the eopper industry from a prolonged period of utter demoralization, during which scores of millions of dollars would have been lost by investors, and a quarter-million or more of working men would have suffered severely, many of them losing their jobs, and the remainder suffering severe cuts in wages. We have the authority of eminent statesmen, totally devoid of business experience, that the Sherman Act is a panacea for all ills of the body politic, yet no sensible business man would do otherwise, if he had the power than to reduce production, at a time when a surplus product threatened not only the small remaining profits but the very foundations of the copper industry. The issue thus is drawn very plainly between our present politico-criminal law, and all the laws of business and of political eeonomy.

Business and Politics.

I have no connection, direct or indircet, with any copper mining company or eopper producer, except that, in

a general way, I have small business dealings with a great majority of the actual copper producers of this and foreign countries, hence I speak without personal prejudice, and not as the mouthpiece of any individual copper interest.

The greatest present menace to the copper industry in the United States is a menace that is common to all branches of mining. The entire American industry of mining is threatened by men operating under the names of progress and reform, whose slogan is conservation, but who are political economists of the Stone Age, and first cousins, in mental capacity, to the Troglodytes. The conservation experts of the forest service are systematically hampering legitimate mining operations throughout the Western States, and both law and justice are disregarded by these conservationists, while the federal departments affected are governed more by rulings than by law. Congress has made the very grave and dangerous mistake of endowing the executive departments of our Government with the power to promulgate rulings that have the force of law, and in some of the departments rulings have been put into effect that not only are arbitrary and unjust, but that also are absolutely illegal, yet the poor miner, who has complied with all the requirements of the law, is liable to see his property, to which he is clearly entitled, both by law and justice, taken from him by the officials of the forestry service, under the slightest pretext, and is denied access to or recourse by the courts. The most odious forms of despotism can show nothing worse, in this particular, than the hideous imposition under which honest miners are suffering in the Western States of our country.

ANACONDA AND THE GUGGENHEIMS.

The conservationists, many of whom might, with greater truth, be termed conversationists, would close the Washoe Works of Montana, the greater reduction plant in the world, with a monthly output valued at millions of dollars, employing thousands of men, and indirectly giving employment to tens of thousands of men, under the childish plea that the smelter fumes are injuring timber on the federal forest reserves—timber that, in a pinch, might furnish fairly good lodge-poles for Indian tepees.

The Guggenheims are the bogey-men with which the conservationists most frequently alarm the public. We have had it dinned into our ears, by innumerable patriots seeking office, and repeatedly set before our eyes, in every yellow newspaper and muckraking magazine, that "the Guggenheims are stealing Alaska." As a matter of fact, the Guggenheims control a copper mine in the interior of Alaska, that is a wonder in its way, yet which cannot be rated at more than a third-class property. The mine, the Bonanza, is a sort of copper-plated gold-brick, in that an interior core of limestone is surrounded by phenomenally high-grade bornite and copper glance. No competent mining man who has visited this property ever has estimated the amount of ore in sight, and safely to be inferred, as capable of yielding more than 100,000,000 pounds of finished copper, a total production equivalent to only one year's maximum output by any one of the six leading copper mines of the world. In order to get this ore out of a wilderness, the Guggenheim interests have built the Copper River & Northwestern Railway, a line of 195 miles length, variously estimated to have cost from $13,000,000 to $25,000,000. The gross value of all the copper contained in the Bonanza mine, taking the outside estimate of tonnage, is considerably less than the lowest estimate of cost of this railway, and the net profits derivable from the Bonanza mine, cannot, by the most liberal figuring, be estimated at more than $4,000,000 to $5,000,000. Instead of being commended for their enterprise and courage in building this railway through an Arctic wilderness, the Guggenheims are held up to public scorn as thieves and robbers. This railway cuts through workable beds of coal, but is prohibited, by the federal authorities, from developing or using this coal, and is compelled to import inferior coal from British Columbia at a cost more than double that of domestic coal if its mining were permitted. Not only does the railway suffer from this arbitrary action by the Federal Government, but the 50,000 unfortunate American citizens who live in Alaska are compelled to pay double or triple the price they should pay for fuel, through the efforts of the conservationists, backed by the Federal Government, to "save" the coal for some future use, at an indefinite date. It scarcely seems strange, in the light of this situation, that mourning was donned in Alaska when the High Priest of conservation reached that land, which the conservationists seem to consider a sort of penal colony. The conservation of our mineral, timber and power resources should be effected along legal and business lines, and not under the guidance of spiritualistic visions.

The reformers, as these gentlemen term themselves, are advocating the Government building and operation of railways in Alaska, and the Government ownership and operation of coal mines, which is state socialism pure and simple, and any man seriously advocating such a policy is a socialist, no matter what he may choose to call himself. It is further advocated, by the junior senator from Wisconsin, and his official and unofficial organs, that the Government also should buy the Copper River and Northwestern Railway from the Guggenheims. Doubtless the Guggenheims will be very glad indeed to sell their railway, which is threatened by tidal floods and glacial floods, with its principal bridge across the Copper River threatened by a glacier itself, but it is difficult to see where the long-suffering taxpayer will benefit by such a purchase.

The Federal Government already has withdrawn immense tracts of oil, coal and phosphate lands, and the next step in this cleverly devised socialistic propaganda will be to withdraw from entry, or inhibit mineral entries upon iron, copper, lead, zinc, silver and gold lands.

The pretext for past withdrawals is that our mineral resources are being depleted so rapidly that there is danger of their extinction, in the near future, unless administered by an all-wise and all-powerful central government, which can make no mistake, and can do no wrong. The figures regarding our natural resources, put forth apparently in earnest, by some of the leading conservationists, are so utterly ridiculous that it is impossible to regard them seriously. There is more iron ore existing in a single county, in my own State of Michigan, than any professional conservationist ever has estimated to exist in the entire world. This is made as a plain statement of fact, and those who think to the contrary are challenged to impeach the assertion.

The lawless actions of the forestry bureau, which is perhaps the most odious of our bureaucratic iniquities, have been of a sort to arouse the alarm of all thinking men who believe in self-government. Apparently it is the cunningly devised scheme of the leaders of the so-called conservation movement, to expropriate the public

lands, now held by the Federal Government in trust for the benefit of any and all citizens who will develop them, and hold these public lands for the sole benefit of the bureaucrats, who will enjoy the usufruct, through a carefully-planned system of leases, by which the water-power, forests, mines and arable lands will be leased, to corporations that are amenable to the benevolent control of the doctrinaires, and to individuals who can be terrorized to conform to the exactions of the bureaucracy. The opportunities for graft that are contained in such a system are almost inconceivably great, and comparing their claims with their actions, the conclusion is irresistible that the conservation movement, as now managed, is not a genuine effort to improve the condition of the American people, but a cleverly devised scheme to deprive the people of their landed heritage, and fix upon their necks the iron collars of serfdom, to the end that a more gorgeous and richly endowed bureaucracy may flourish upon the soil of what once was a free country.

It is said, and apparently with reason, that the spy system of the United States is now the finest and most extensive in the world, excelling even those of Russia and Turkey, heretofore the most progressive nations, in the matter of thoroughly organized espionage. We also have the benevolent activities of an attorney-general who is now vigorously prosecuting the kindling-wood trust. It is obvious that the shaving-paper combine and the office-towel monopoly had better watch out, for their turn may come next. Why does not the attorney-general prosecute the labour unions, which are trusts in the meaning of the Interstate Commerce law, existing in open defiance of the beneficent provisions of the Sherman Act? The answer seems obvious. The present activities of the United States Department of Justice, as it is termed, officially, afford a spectacle for gods and men.

Business throughout the United States is suffering from uncertainty—which has been accentuated, rather than decreased, by the recent decisions of the Supreme Court, which read into the Sherman Act a provision that only "unreasonable" restraint of trade should be punishable, under the terms of this Act. As Richard Olney justly remarked, this leaves the Sherman law about as clear as if Congress were to pass a law stating that only a "reasonable" tariff should be imposed, and leave the adjustment of all duties to the Supreme Court of the United States.

This nation has been made great and prosperous by the initiative and enterprise of the individual, yet the theorists bid us throw aside the habits and course of conduct of centuries, and depend solely upon the initiative—God save the mark—of the bureaucrats. Why not speak out boldly, what all sensible and patriotic citizens are thinking, throughout this country? We are suffering from a most odious form of bureaucracy, fortified by an extensive system of paid spies, an organized claque, a clever press bureau, and the systematic support of that section of the press noted mainly for its dubious motives and devious politics. Some citizens with defective hearing take the clamor of this portion of the press, desirous of cheaper wood pulp, for the real voice of the nation. It is time that the yellow newspapers, muckraking magazines and purely political conservationists were told to stand aside, and permit the Federal Government to be run, once more, in accordance with law and common-sense. Some of the gentlemen who are preaching progress and conservation, have combined moral platitudes with business turpitude, and label their product as reform. In the name of progress they bid us turn our faces to the rear; in the name of conservation of our natural resources, for generations yet unborn, they forbid us to utilize the mineral, power and timber resources required for the needs of the present generation. Their plan of state ownership of mines and water-powers is state socialism, very thinly disguised. These men are enemies of the republic, who, under the specious cloak of declamatory patriotism, would rob us of our right to self-government.

Our worthy President takes the stand that because the Sherman Act is law it must be enforced rigidly, regardless of consequences. If this be the case, it necessarily follows that all federal laws must be rigidly enforced, regardless of consequences, and it would be interesting to learn why our Federal Government does not enforce, or even attempt to enforce, the fifteenth amendment to the Constitution of the United States, which reads as follows: "The right of citizens of the United States to vote shall not be denied or abridged by the United States, or by any State, on account of race, colour or previous condition of servitude." Is it possible that the Sherman Act takes precedence of the Constitution?

The Slocan District of British Columbia

The condition of the mining industry of the Slocan district of British Columbia may be stated to be more promising now than for ten or more years past. This situation is not due to the prevailing prices of silver, lead, and zinc, which are the chief metals produced in the district, for yearly average market prices have been low for several years. Rather is the prospective early return to prosperity in several of the mining camps of the district due largely to results of deep-level development, these having shown that ore occurs at such depth as to assure the permanent and profitable working of some of its mines for a number of years, thereby encouraging the expenditure of much money in doing development work on a scale not previously carried out.

The notes that follow, while by no means fully descriptive of progress made and results being achieved, will serve to in some measure convey an idea of the advance made during recent years, and to indicate grounds for the confidence felt for the future of the silver-lead-zinc mining industry of the Slocan. The various mines are dealt with generally in the succession in which they occur, going easterly from Slocan Lake.

STANDARD SILVER-LEAD COMPANY.

This company continues to make good progress with the development and equipment of its Standard mine, situated in Four-mile camp, near Slocan Lake. The water supply system has been completed, the compressor

installed, and started supplying air for machine drills in the mine, the concentrating mill completed and connection made with the water line for power purposes, and the aerial tramway given its preliminary run, conveying ore from mine to mill.

In the mine, the chief work of late has been the further development of No. 6 tunnel, which is 190 feet, vertical depth, below No. 5. In this adit zinc ore was encountered at about 1,800 feet from the portal; this continued for nearly 100 feet, when lead ore was met with. The tunnel was driven another 200 feet ahead, when it cut 8 feet of zinc ore, which was drifted on both ways for a short distance. Driving beyond this vein is still in progress.

From the 1,900-ft. point in the tunnel a turn was made to the left, following the lead ore. At 200 feet from the main tunnel the vein is about 12 feet wide, the first-class ore varying from 3 to 8 feet in width, the remainder being concentrating ore. The question of whether or not this shoot of ore is the downward continuation of the ore body occurring in No. 5 has not yet been determined. Later a raise from No. 6 to No. 5 will prove whether it is or not.

Work in the mine is now being done with machine drills instead of hand, as heretofore, consequently much greater progress is being made in doing development work.

SILVERTON MINES, LTD.

The development of No. 7 level of the Hewitt-Lorna Doone group is being continued. As far as it has been driven it has passed through three ore shoots. This adit is now in about 900 feet, and it has developed much ore, nearly all high-grade, and some of it very rich. Raises are being driven between Nos. 6 and 5 and Nos. 5 and 4. The distance between levels is 110 feet, vertical height, so that these raises will give 220 feet of connection between Nos. 4 and 6. A raise has already been made between Nos. 7 and 6, and another is being made between an intermediate (above No. 7) and No. 6. When the raises above No. 6 shall have been completed they will be used for passing ore down to that level, at the portal of which is situated the upper terminal of the aerial tramway from the mine to the Wakefield mill, and this will admit of doing away with the "baby" tramway from No. 4 down to No. 6.

No ore is being stoped at this mine, for the ore bins at both mine and mill are quite full, awaiting the completion of some repairs and renewals at the mill, prior to having another mill run. There is on hand more than 1,000 tons of clean picked milling ore—that is, with the high-grade ore sorted out for shipment to the smelter, and the waste picked out so as to leave the mill feed of a suitable grade for milling purposes.

Experimental runs have been made with the unit of the Elmore Vacuum plant recently put in at the mill, and it is understood that results have been encouraging. Some necessary adjustments of mill machinery have lately been made, preliminary to giving the Elmore process a further trial. The probabilities seem to be that the process will be found effective for the recovery of the zinc content of ore of the character usually treated at this mill.

VAN-ROI MINING COMPANY.

This company's concentrating mill is treating 125 to 130 tons of ore a day, and is producing two kinds of concentrates, namely, silver-lead and silver-zinc. The tonnage of ore milled this year to date is nearly 25,000 tons. The mill is new, having been completed only last March, since the middle of which month it has been steadily operated.

Orebodies are being developed on three levels of the mine—those of both the main vein and the Beryl vein, which had opened later. It is expected that ore production will be well maintained from both veins, and that the year's output of ore and metals will be satisfactory.

MINES NEAR NEW DENVER.

The several mines already mentioned, while nearer to Silverton, are also within easy reach of New Denver. There are others in the near vicinity of the latter town, among them the Mollie Hughes and Apex, which are still being worked, and the Sweetgrass, California, and others that were operated earlier in the year, though at present inactive.

Mollie Hughes.—Negotiations were carried on by Vancouver men for some time with a view to acquirement of this mine, the quartz veins in which contain gold and silver. So far as information was received, though, no definite arrangements have yet been made to carry out this proposed transfer of the property. Meanwhile it has been worked on a small scale, and some ore has been extracted and shipped to the smelter at Trail.

Apex.—The Apex is situated on Silver Mountain, about a mile and a half from New Denver, opposite New Denver Canyon. Six men are taking out and sacking ore for shipment, and they have one carload ready. The vein has been stripped for 257 feet, and it shows ore stated to be of shipping grade, about 18 inches in width, along that length. The ore is what is known as "dry" ore, with fair-sized bunches of silver-lead ore intermixed. As yet the vein has not been proved deeper than 30 feet. An ore-house and blacksmith shop have been built, and men are now employed in erecting a house for the accommodation of miners and their helpers, of whom 10 to 12 in all will be working here through the winter. The Apex is owned by a company that some time since acquired this property with the Sunset above Cody, and other mining interests of the late George Hughes, one of the pioneers of the Slocan district.

Other Mines.—It is probable several other mines in the neighbourhood of New Denver were worked during the year, but no information was obtained concerning them during the brief time at disposal in that locality.

IDAHO-ALAMO GROUP.

About four miles up Carpenter Creek from New Denver, and rather more than a mile below Three Forks, the Alamo concentrator is to be seen, situated close alongside the Nakusp and Slocan Railway, from Nakusp on Arrow Lake, around by Rosebery, on the upper part of Slocan Lake, and thence by New Denver Canyon and Three Forks to Sandon. The disused concentrating plant and the ruins of an aerial tramway are standing monuments of the profitless expenditure of a large amount of money obtained from Great Britain and spent by a well-known English mining engineer, of whose management local miners have not a very high opinion.

It is stated that $80,000 worth of ore was taken from one part of the Idaho mine, and that without reaching a depth of more than 40 feet. The statement was not verified, but is here given simply for what it is worth. However, this much is fact—that the property is now

under lease and bond to Thomas Avison, of New Denver, who is taking out ore on a small scale, and is confident he has a mine that will again come into prominence among the shipping mines of the district.

SLOCAN STAR MINES.

A commencement has been made to drive the long, deep-level tunnel at the Slocan Star mine, as recommended by Mr. A. G. Larson, M.E., of Vancouver, B.C. The organization and incorporation of the new company, formed for the purpose of acquiring the Slocan Star and Rabbit Paw groups of claims, situated near Sandon, was effected in October, and work under the new auspices commenced about the beginning of November. Mr. Oscar V. White, who has long been superintendent for the Byron N. White Company, hitherto operating the Slocan Star group, remains in charge of operations on the consolidated property.

Beside commencing to drive the long tunnel, the work of retimbering the old workings, fixing up the stopes ready for the extraction of ore, etc. (in the ground, concerning which there was litigation that extended over years), has been taken in hand. Later an ore pocket will be put in below the new tunnel, and picking tables placed between that bin and the concentrating mill. It is expected that ore stoping in the older parts of the mines will be commenced early in the New Year, and that thereafter production will be resumed of both picked crude ore, for shipment to the smeltery, and of mill feed, for concentrating.

SEVERAL MORE SANDON MINES.

Beside the Slocan Star-Rabbit Paw group, there are the Ruth-Hope, Byron N. White, Richmond-Eureka, and Payne groups of claims, all in the vicinity of Sandon, though the last named is more than a mile away from that town, which is already benefitting, and will continue to do so in increasing degree, from the resumption of work on the Slocan Star and Payne mines after years of idleness on both.

Hope.—No recent particulars have yet been obtained concerning the Hope, but it is known development work is being continuously done in this mine, and sufficient ore is being extracted and shipped to provide for the payment of about 15 men employed.

Richmond-Eureka.—The Byron N. White property, formerly a part of the Slocan Star group, has not been worked lately, operations having been suspended last spring. But the Richmond-Eureka, which has been developing some of the same veins as occur in the Byron N. White group, has steadily continued both development and mining silver-lead ore for shipment to the smeltery at Trail. Latterly production has been on a smaller scale than some time ago, but the Consolidated M. and S. Co., owning this property, is continuing exploration for other shoots of ore, which it is expected will be opened when development shall have been sufficiently advanced.

Payne.—The deep-level development work to be done on the Payne is regarded as of great importance to the district, for if successful it will prove one more addition to the accumulating evidence that the ore shoots in the Slocan district live down to much greater depth than had previously been believed. Further, the fact that this important work is to be under the direction of Mr. W. E. Zwicky, of Kaslo, manager of the Rambler-Cariboo, on which property he did the pioneer deep-level exploratory work in the district (undertaken on his strong recommendation), induces confidence that if the Payne ore bodies continue to greater depth than has yet been explored in this mine, they will probably be found by Mr. Zwicky. It is intended to drive a cross-cut tunnel about 3,300 feet, starting from the Sandon side of the Payne Mountain, and cutting the vein at about 675 feet below the old No. 8 level of the Payne mine. Mr. George Clark is foreman, with 8 or 9 men under him. Camp buildings are being erected preliminary to commencing tunnel-driving.

RECO MINE, CODY.

Prospects are bright once again for the Reco mine, situated above Cody, Slocan. About 18 months ago driving No. 11 tunnel was commenced, thus to explore virgin ground. Only a small working was engaged, and these men have driven 630 feet, the last 180 feet having been in ore. Air being bad, they went back about 130 feet and commenced raising, to make connection through to No. 9, which they had already extended about 200 feet, to get beyond the orcshoot opened in No. 11.. The raise will be 89 feet, vertical height, and about 110 feet on the incline. At 30 feet up there was between 18 and 24 inches of solid silver-lead ore. When this raise shall have been put through the extraction of ore will be undertaken, and thereafter there should be a good output made, with a prospect of its being maintained over a comparatively long period.

OTHER CODY MINES.

Other mines in the vicinity of Cody that are being worked are the Twilight, Noble Five group, Sunset, and Surprise.

Twilight.—The Twilight is owned by Harris and Kelly, of Sandon. The lower extension of the Reco-Goodenough vein occurs on this property. Last winter two leasers commenced to drive No. 2 adit on an adjoining claim, known as No. 1. At about 175 feet in from the portal the vein was cut, on Twilight ground, and it was drifted on 300 feet, when it was decided to raise to No. 1 adit, the portal of which is on the Slocan Sovereign claim. The vein is well-defined, and for 180 feet has been about 4 feet in width, but so far the good ore in it has been but a small paystreak, ranging generally from 2 to 4 inches, though once it widened to 18 inches. There have been three different parties of leasers working here, and several small shipments of ore have been made. A site has been surveyed for opening No. 3 adit at a vertical depth of about 100 feet below No. 2. Quartz. indicating the presence of the vein, has already been found in a creek. It is proposed to commence work on this new adit next spring.

Sunset.—On the Sunset, which has been opened on both the Cody and McGuigan basin sides of the mountain, No. 8 tunnel is now in about 1,300 feet. Ventilation being insufficient for the miners to continue driving a raise is being made in the vein to the surface, a distance of 100 feet, for air. This raise was started at 40 feet back from the face of the adit. It is intended to continue working here throughout the winter; supplies to last until spring will be taken up to the mine before the snow shall become too deep for the pack train to reach the camp. No pay ore has yet been found on this level, only iron and zinc oxides. It will require the adit to be driven 300 feet farther to get under the long ore shoot already mined in levels higher up the

mountain. That shoot was 300 feet in length, and confidence is felt that it will also be found in No. 8, and of similar length.

Surprise.—The work of making the long raise from the 1,100-ft. level of the Surprise through to the bottom of the old workings, a distance of about 830 feet, approaches completion. It is expected connection will be made about the end of the year, after which work will probably be suspended until next spring, conditions being unfavourable for getting in supplies in the depth of winter. This raise is the longest in the Slocan district, and the work of making it has been tedious and extended over a lengthy period. However, Mr. Alex. Smith, who has persisted, notwithstanding that he has had many discouraging experiences in carrying on the work, has the satisfaction of knowing that the raise has passed through the best shoot of ore yet opened in this mine, and one that promises to give him and his partner good returns after the requisite provision for ventilation shall have been made. The deep level from which the raise has been made is an extension of one of the Last Chance tunnels, which was driven first in Last Chance ground, then through part of the Noble Five group property, and finally into the Surprise.

Noble Five Group.—An intended visit to the Noble Five was not made, owing to a heavy snowfall having taken place on the day the walk from Sandon was to have been undertaken. However, this much was ascertained two months ago, namely, that development work on the Deadman claim of the Noble Five group had resulted in the discovery of a shoot of silver-lead ore of excellent grade, not previously opened, and of a body of clean zinc ore of a percentage high enough to allow of this ore being shipped crude to the smeltery. It would appear, therefore, that in common with other mines in Cody camp, the Noble Five may be expected to again become a producer on a comparatively important scale.

THE RAMBLER-CARIBOO GROUP.

There have been between 40 and 50 men working all the summer and autumn on the property of the Rambler-Cariboo Mines, Ltd., situated in McGuigan Basin, which used to have its outlet at a point on the Kaslo & Slocan Railway, about equidistant between Whitewater and Sandon. Developments in the Rambler-Cariboo mine in recent years have done much to restore confidence in the mining industry of the Slocan district and to encourage mine-owners to undertake deep-level exploration. Since the big adit—it is nearly seven-eighths of a mile in length—was driven five or six years ago, and the old workings thereby drained, much development work has been done below the 800-ft. level, which was the lowest in the mine prior to driving the 1,400-ft. level. Gradually the downward continuation of the ore shoots has been demonstrated, until now it has been proved that the highest-grade ore yet found in quantity in the mine occurs on the 1,200-ft. level. Three ore shoots have been opened in the vein on this level, which has been driven 450 feet south from the main raise. The shipping ore in the first of these does not occur to as large a width as that in the second. The vein is big, in places up to 10 feet between the walls, but the ore in the first shoot is not nearly so wide as in the second, in the former ranging from 8 inches to 2 feet, while in the latter it runs from 1 foot to 5 feet of clean ore, with 2 to 3 feet of milling ore as well. No stoping has yet been done on either the 900 or 1,200-ft. level, but about 10 feet of ore has been stoped on the 1,000-ft. level. Shipment of ore to the smeltery has been delayed by the state of the wagon road to Three Forks, the upper part having latterly been a snow road and the lower only suitable for hauling on wheels. Now that snow has fallen low down the valley ore-hauling to the railway will be undertaken. If the weather proves favourable for teaming, some 150 to 200 tons of first-class ore will, it is expected, be shipped to Trail during the latter half of November and in December. When the mine was visited on November 11, there was 50 to 60 tons of ore in the ore-house waiting for the snow to fall to allow of shipment. The erection of an aerial tramway down to the railway, and the building of a new concentrating mill alongside the track will be undertaken next spring. The machinery and equipment of the old mill will be used in the new building, for which purpose it will be taken from the old mill building, situated high up the mountain, to the new mill site, on Seaton Creek, at a distance of about 6,700 feet down the mountain side from the portal of the 1,400-ft. adit level.

Extension Group.—The Rambler-Cariboo Extension property consists of a small group of claims situated in the vicinity of the Rambler-Cariboo group. These were formerly known as the Adams claims. They are being developed from the main adit of the Rambler-Cariboo, from which a drift has been run on a vein cut by that level. Work was commenced by the Extension Company on October 1. It is intended to drift right through the property. The drift at this level will give a depth of about 550 feet.

Rio.—The Rio is at the head of the McGuigan Basin, about a mile from the old Rambler-Cariboo mill. The vein was cut by a cross-cut tunnel at 480 feet from its portal. Two shoots of ore have been found in the drift, but this level will have to be extended about 100 feet before it will be under the big showing occurring 150 feet above. Work is to be continued throughout the winter, for which purpose the necessary machinery has been taken up to the mine.

The Washington, situated on the Payne Mountain side of the basin, was worked by a few men during the first half of the year, but not latterly.

LUCKY JIM ZINC MINES.

No. 6 level of the Lucky Jim mine, near Bear Lake, Slocan, has been driven 1,134 feet. At 1,009 feet from the portal the lime dike was entered, but no zinc has yet been cut on this level in the lime, although the tunnel was advanced 125 feet in this rock. Drifting on the footwall of the lime dike is now being proceeded with, the expectation being that the ore will be found along this side of the dike. Two shifts of men are at work, and about 4 feet per day is being driven.

There is much ore available for stoping above No. 5 level, but none will be extracted until after the provision of railway transportation facilities, now in hand by the construction by the C. P. R. of a spur from the Nakusp and Slocan Railway, leaving this line at a point about one mile above Three Forks. Much of the grading has already been done, and Camp No. 3, within a mile of the Lucky Jim mine, is being established.

IN WHITEWATER CAMP.

Notwithstanding that in the summer of 1910 forest fire destroyed the concentrating mill at the Whitewater mine, and much else of the surface plant and buildings, Mr. John L. Retallack and his associates in this mining

enterprise, have prosecuted development work with renewed energy, chiefly in the deep of the mines, and, in small measure, in the upper part of the property.

Formerly there were two companies engaged in operating this group of mines, namely, the Whitewater and Whitewater Deep, respectively. Then a syndicate leased the Whitewater and part of the Whitewater Deep property. Still later Mr. Retallack organized a company styled The Deep Mine, Limited, and this last-mentioned organization undertook important deep-level development and drove the main level, or No. 14, of the deep of the mines a distance of 2,000 feet. Afterwards raising to No. 10, of the Whitewater Deep, was commenced, with 540 feet on the incline required to be driven to connect these two levels. This raise was up about 100 feet when the last fire disaster, already referred to, compelled a suspension of work for the time being, for not only had the upper part of the mines lost practically all its surface buildings and plant, but the compressor plant of The Deep was badly damaged, the camp destroyed, and all other facilities for continuing work swept away. The crowning loss was that of transportation facilities, for the railway for several miles from Whitewater towards Kaslo was rendered quite useless, bridges and trestles having been burned and the track badly damaged. Eventually, though, communication by wagon road was provided, and materials and mining supplies were sent in, new buildings erected for The Deep Mine, Ltd., the compressor made fit for service, and underground development was resumed. Since then the main rise has been put through from No. 14 to No. 10, connecting with the latter at about 1,500 feet from its portal, and levels Nos. 13, 12, and 11, respectively, have been opened from the raise. These levels have been driven, together with various cross-cuts off them, in search of ore shoots, and this exploratory work is being continued, the object being to have the mine open and in a position to produce ore whenever railway transportation facilities shall again be provided. Meanwhile, ore stoping is being done in the upper mine by the John L. Retallack Co., so that two or three cars of ore may be sent out before deep snow shall make hauling impracticable at the high elevation at which the property is situated. This ore is to be hauled in sleighs to Sproules, and be sent by the Kaslo & Slocan Railway to Kaslo, for shipment thence to the smeltery. Telephone communication between the mine and Kaslo, over a distance of nearly 20 miles, is being established, so this means of communication will be available shortly.

CONCLUDING OBSERVATIONS.

The Slocan district is so extensive and the mining properties scattered over it so numerous that much more space than has been taken by the foregoing notes would be required to cover it exhaustively. There are many mines not now being worked that may be expected to again have attention and their ore deposits be opened. However, ample has been written to show that the district is steadily growing in favour with mining men, possessed of capital for the development work requisite to make accessible the large and valuable mineral resources of the district. Not only are there many mines within the area dealt with, somewhat briefly as regards details of individual properties, in the foregoing survey of the present situation, but there are as well numerous properties in both Ainsworth division, in eastern Slocan, and Slocan City division, in the western part of the district, that are not here noticed.

There is little room for doubt that the district is making satisfactory progress toward a period of productiveness and prosperity in connection with its mining industry altogether beyond what a few years ago would have been regarded as possible. Its progress, if not spectacular, has been substantial, and fortunately thus far almost free from the malign influences of unprincipled promoters desirous only of "mining the public." It is to be hoped that mining on paper only will be sternly discouraged, and the best interests of the district and its mining industry be thereby protected.

THE NOVA SCOTIA MANGANESE COMPANY.

Through the courtesy of Mr. E. A. Saunders, secretary of the Mining Society of Nova Scotia, we are able to publish the accompanying photo. It represents the concentrating mill that has just been completed on the property of the Nova Scotia Manganese Company, Ltd.

The mine is situated in Lunenburg County, about 10 miles from tidewater, and 13 miles from the town of Windsor.

The manganese veins were discovered by Ernest Turner, of Mill Road, Lunenburg County. Associated with him at first were Dr. Henry Kane, Mr. E. N. Dimoek, and others. A joint stock company was recently formed, and the work at present is being conducted in its name.

The main shaft is down 165 feet. To the west a drift has been run for 115 feet. High grade manganese ore averaging 18 inches in width, shows continuously through the drift. Shipments of ore are being made to Trenton, near New Glasgow, where a glass-making establishment is situated.

CANADIAN MINING INSTITUTE.

Porcupine Meeting.

The following notice has been distributed to mining men throughout Cobalt, Porcupine, and Toronto:—

Dear Sir,—Under the direction of the undersigned committee, a branch of the Canadian Mining Institute for Porcupine is being organized, and a general meeting is called for the 16th December, at 8 o'clock p.m. at South Porcupine.

It is proposed at this meeting to elect officers for the year, and to organize the branch in as effective manner as possible. It is proposed to have a standing committee to obtain papers from the members, to arrange for monthly meetings, and to keep up the inter-

st in all ways possible. Rooms will be rented and urnished with magazines, books, maps, writing ma-erial and specimen cabinet.

After the business of the meeting is completed short ddresses will be given by visiting members, and three r four short papers, dealing with sampling and other ubjects of interest in this the initial stage of the de-elopment of the gold camp, will be read.

The meeting will close with a short musical program nd refreshments.

On the day following, the guests and other members who desire, will be shown over the camp. Unique op-portunities will be afforded of seeing the various show-ngs of gold, and an opportunity seldom afforded of comparing the various finds in Porcupine.

We have been fortunate enough to secure the presence of a number of prominent members of the Institute, including Dr. Frank Adams, the president.

We trust that you will find it convenient to be present. Members advising this committee before the 1st of December will be afforded accommodation at the various mines.

Committee:—
C. E. WATSON.
H. C. MEEK.
C. G. CAMPBELL.

Address the Secretary, Box 514, South Porcupine, Ontario.

Stock Value and Mine Value

By DR. A. C. LANE.*

(Continued from last issue).

Class B.—Explorations or failures. Average fluctuation factor 4, rarely under 2.5.—On the other hand, if we take the remaining mines which sold below $10 in 1901, we find that their fluctuation factor is rarely less than 2.5 and averages nearly 4, and that of the seventeen, seven were worth nothing if we compute their value in 1901 from the dividends and assessments since and their selling price at the end of 1910. Of the remainder, in only two was their value (similarly figured) more than the lowest price of the year.

Comparison of prices with worth.—Now what does this difference in range of fluctuation mean? And is this factor 2.5 anything but arbitrary? In order to determine this I have computed as best I might the actual worth of the mines at the date 1901, by discounting at 7 per cent. coming dividends, and their low selling price in December, 1910. This latter was pretty nearly the ratio of price at which those of them that were to go into the Calumet and Hecla merger were to be taken in. I then debited the assessments that have been called in the meantime, and when the amount of the assessments was greater than the positive amount derived above, I have simply written the word "minus" and assumed that the holder refused to pay indefinite assessments. I have given this for the year 1901 rather than 1899, but the deductions I shall draw will be equally applicable to 1899, and the worth will not materially vary except that all the cheaper Class B mines would have been worth at least 14 per cent. less on account of interest, and in some cases about $24 less on account of assessments that were called in 1899 and 1901. But as some of the mines were organized in 1899 it seemed better to compare with a year when they were fairly organized, like 1901.

The lowest prices for 1899 were very much the same as the worths, and this is true for 1901 for the Class A mines. These were seasons of great prosperity and inflated prices. On the other hand, in 1903 and 1904 the worths are still within the range of the prices of the year; rather nearer the top in 1903, but just about half way down in 1904. In other words, the stocks of the first class (A) vary about a 7 per cent. valuation—in boom times yielding a 7 per cent. average only if one buys at the very best prices of the year, and at the higher prices of the year yielding barely 4 per cent. It will be remembered that Lawson, in the days of "Frenzied Finance," used to say that copper stocks were coming to a 4 per cent. basis. On the other hand, in relatively dull times, as in 1903 and 1904, which were after all but "semi-panic years," one could easily obtain the stock on a 7 per cent. basis. If the very best prices of the year could be obtained the yield would be nearer 10 per cent., and at the higher prices of the year the yield would be considerably below 7 per cent.

Meaning og 2.5 fluctuation factor, range from 10 per cent. to 4 per cent. yield. Limitations of activity.—We can now see a possible meaning for value 2.5 as a limit to the fluctuation factor of this Class A. It may mean this, that in Class A the yield is approximately ascertainable in dividends, and when they are forced to such a value that there is only a 4 per cent. yield on them, or anything like it, there are very few who buy an uncertainty yielding no more than a certainty; and that, on the other hand, when they drop to a point where they yield 10 per cent., a lot of people who have private opportunities to invest at 10 per cent. in non-marketable securities, find it now worth while to invest in these stocks which have the added advantage of marketability and yield.

It may then be that this fluctuation factor, 2.5, represents the ratio between the 10 per cent. yield which will draw in the man who has the best opportunity for investment, and the 4 per cent. yield, which even savings banks will give.

Reason for greater speculative value in Class B.—The mines grouped under Class B, selling sometime in the year for less than $10, are usually the explorations and failures. Most of the Michigan mines shares, while the par value is $25, are put on the market marked initially $8 to $10 paid in, representing the land and the cash needed for development up to the point where it is seen whether a mill and heavy equip-

*Professor of Geology, Tufts College.

ment is needed, in which case assessments are called. Consequently these mines will generally represent properties that have not in exploration found anything up to date, or old mines that are worked out or proved failures. If we go back to 1880 we find the same thing true. Very often a mine ultimately successful goes below the initial price at which it is put on, but the majority of those going below $10 have never paid a cent in dividend. Taking the list in June, 1881, the total of the lowest selling prices of Class B was from $37 to $41. The value, judging from their dividends and selling price in 1910, was only something like $12.45. On the other hand, the cost of a share of each of the stocks selling over $10 would be $384 or more, but would be worth discounting on a 7 per cent. basis their future dividends, $581.50. In other words, the yield is more than 7 per cent., and very nearly the 10 per cent. which we have said might be expeeted from unlisted copper stock. This is due to the fact that the Calumet and Hecla are selling on a 7 per eent. basis referred to its current dividend without allowance for the increase which began in 1896. In 1901, though the Class B mines make a better showing (owing solely to the presenee of Trimountain among them, where it did not belong that year, although it went below $10 in 1899), their lowest prices sum up to $67, but their dividend worth was $74.16, of which $19.75 must be assigned to Trimountain. I thought it right to include Trimountain to represent the fact that among these cheaper mines there is an oceasional fair one. It is pretty clear, however, whatever figures one takes, that it is the lowest annual value of these cheaper stocks that is nearest the value measured by yield, and is sometimes a little less than that value, or sometimes greater. That value is given by two or three out of the fifteen or sixteen which will ultimately prove sueeessful.

Clearly then, the increase in the fluctuation factor is very largely due to an increase in range upward, not an increase in range downward. It is an added value given by organized speculation. It is not an added value due to marketability. The higher priced copper stocks have that already. In figuring the worth of the Class B stocks on a 7 per cent. basis I have already allowed for that, if my previous contention that 7 per cent. is a fair yield for a listed copper stock is correct. If we could say that the average value is exactly the mean between the highest and the lowest priees (which it is not) we could say that the fluctuation factor made the stock worth two and one-half times as much as before.

It must be remembered, too, that these stocks are of relatively little worth per share, and the case is something like the difference between a celluloid and an ivory poker chip. The celluloid poker chip would be as useful as the ivory poker chip. The value as chips is not an addition in a given ratio to the value of the raw material of which the chips are made. Therefore, it might not be fair to discuss the "poker chip" or fluctuation value as though it were an addition in a certain ratio to the value of a stock. Indeed, the more expensive stock with less fluctuation costs more to carry to get a given profit by fluctuation. It might be fairer to consider it as the addition of a certain amount to the value of a stock regardless of its value otherwise. An average difference in price from high to low in these smaller stocks would be something like $10 in 1899 to 1901, which were speculative years, whereas, in 1903 and 1904, the amount would be only $4. It might be fairer, then, to say that the value of activity was an addition on the average of $2 to $5 a share to the stock rather than to estimate it as a percentage of the whole cost of a share.

Loss of fluctuation value in consolidation. — This gives us the reason for the considerable protest made by smaller speculative mines like the La Salle, in going into the Calumet and Hecla on the terms proposed. Each share of the cheaper mines was assigned a part of a higher priced share. The prices at the time of merger were thought to be low, though they have been much lower since. Still they were values that were near the lowest for the year 1910. Assuming the ratio was fair enough if based on probable definite returns, but that the consolidation values were close to the low prices for the year, the smaller mines would have been reasonably sure to sell for two and one-half times more, and on the average for four times more, than their consolidation value; while the rise they might obtain in their high-priced share would not be nearly so much. As a matter of fact, however, the prices did not rise during the year 1911 (up to date).

Effect of Struggle for Control on Value in General Slight.

For the effect of the fifth factor, that is struggle for control, I have not been able to derive any average figures. Up to this point, I have been able to analyze fairly satisfactorily (at least to myself) the kind of effect and, to some extent, the amount of effect of various factors and the influence of organized speculation thereon. This last factor I ean not at present isolate.

Buying for control is of two kinds. There is the slow, quiet, unostentatious accumulation when the real purchasers are so far as possible unknown. The effect of this, in as much as the people who are buying for control are generally well informed, might be expected to raise the lower prices rather than to increase higher prices. It is eoneeivable, however, that manipulation of one kind or another might depress prices while buying for control is going on.

The seeond type of buying is seen when a fight is on and a few shares are enough to give control one way or another. The Union Pacific panic price is the standard illustration of this. So far as I can judge in the Miehigan field the highest and lowest prices seem much more closely correlated with other factors than with the struggle for control. It may be that the activity and wide range of prices in Osceola in 1907 was due to the strnggle for control, though the high price for that year is, after all, only capitalizing the dividends of that year at 7 per cent. By this I do not mean to imply that the struggle for control does not have an effect upon priees. It simply implies that the kind of men who struggle for control are ordinarily so well posted in shrewd buying that their struggles hardly affect the annual range of the price. This is where a personal element may enter in the stock market and might not apply in other fields. The management of the Calumet and Hecla have a reputation which leads one to think that they would not put out false rumours to depress a stock that they wished to buy. On the whole, the effect of especial desire should appear in the average price.

Conclusion.

The net result of our essay is this, that organized speculation adds marketability and thus about 50 per cent. to the value of stock; and, in the cheaper

stocks especially, it increases the range of fluctuation and incidentally the average price paid for them, leaving the lowest prices of the year not far from the worth that would be computed for them (from their ultimate return either in depreciation or dividends, on the 7 per cent. basis which holds on the average for listed copper stocks), but raising the highest values so that they are about four times as great as the low and consequently increasing the average value very materially.

Application in Taxation.

There seems to be a curious application of our conclusions to the question of tax assessments, leading to a possible confirmation of them. If, in assessing a mine, it should be deemed fair that various mines should be assessed for taxation upon their yield, present or prospective, without regard to whether their stock was listed or not, or whether the stocks were in small units or large, as being matters which pertained to the stock rather than to the mine; then the value of a mine stock should be discounted by a factor representing the increase of value of the stock due to marketability or fluctuation. I do not say that this is so, but it is at least a curious coincidence that I find in the newspapers the following item: "The Board of Supervisors of Houghton County are said to grade the properties for taxation as follows: For undeveloped properties, 40 per cent. of the stock market value; for properties developed but not yet producing, 50 per cent. thereof; for regular producing and dividend paying mines, 60 per cent. thereof."

Now this 60 per cent. valuation for regular producing and dividend paying mines is about what (quite independently) has been found to be the ratio of a listed and a non-listed security of equal uncertainty. That the stock market value is very much more inflated for the undeveloped properties than the developed, is shown by the lower ratio at which their assessed valuation is taken. In fact, if we assume that the average value of the Class A mines (the average fluctuation factor being 1.6) would be found by multiplying the lowest price by 1.34, and that this will practically be the value on a 7 per cent. basis, of all the copper stocks, of which they make up over 90 per cent in value; and in the same way take the average value of the undeveloped properties as 2.4 times their low values, the ratio would be of the same order as the ratio 60 to 40. This ratio, 60 per cent. to 40 per cent., is merely a shrewd business man's general estimate of the relative value of such properties as compared with the stock market values from a mining man's point of view. But as the Board of Supervisors of Houghton County is to a very large degree composed of the agents and superintendents of the various companies, their estimate is well worthy of consideration.

It will be noticed that J. R. Finlay recently placed the Michigan mines for the State Tax Commission at $69,815,000, although their average earnings, he says, were $8,240,000. This, it will be noticed, is a return of about 11.6 per cent., and as the mines themselves have sold in the stock market in the year 1910, taking the average of the highest and lowest selling price, at $130,365,047, the ratio thus found by the comparison of Finlay's value for taxation with the average selling value is about 54 per cent. Thus his estimate is only 10 per cent. to 20 per cent. less than our conclusions might lead to.

While such discounts from the selling value by assessors have often been considered dishonest (and have unquestionably led to dishonesty) yet so long as the basis of taxation is that of "cash value" (as in Michigan and elsewhere) some such adjustments are inevitable, for, as has been shown, the worth of a mine is often much less than the worth of a share multiplied by the number of shares just as the worth of a number if city lots is very much less than the price per lot multiplied by the number of lots. But it would carry me too far from the theme of this essay to follow this longer. The point to be emphasized is that there inheres in the stock a value created by organized speculation which does not inhere in the mine upon which the stock is based. As to whether all of this should be considered value, depends upon just how value should be defined. Upon this point economists differ, nor do I propose to thresh the question over. Whether the poker chip can be considered to have value in Ruskin's eyes is one question. That it is valuable as an article of commerce is beyond question, and ready marketability at least is a factor which can easily be seen to be of social value. The question of the reality of fluctuation value and of its use to the community as a whole is a more complex one. If such range of fluctuation is necessary in order to get the money with which to develop mining enterprises, which are particularly essential to modern progress, if it is necessary that in grouping together the shares in eight enterprises (of which only one shall be successful), the range of fluctuation must be such that the chances of return are one-quarter of what they should be on the chances of yield alone, such a fluctuation may be socially desirable; but organized speculation is hardly expected to be perfect, and the prospects of "paper" profits in "organizing" and "listing" companies seem excessive compared with those which may be acquired in developing the resources of the lands which serve as a basis for those companies. In fact, I was surprised to find how heavy the chances were against the cheaper copper stocks, and how relatively good a showing the more expensive stocks made. This conclusion is not to be confined to Michigan copper stocks, for it depends on general principles. Try it yourself in some other field. If the average yield of the cheaper stocks could be made to bear the proportion to their mean prices that obtains in the better stocks, so that in purchasing a number one might expect a 7 per cent. yield, although one's chance of success in any one stock might still be very low, it would seem that the money for new enterprises might be more easily gained and fairly rewarded. Greater care in listing may tend to this goal. It is possible that something of this sort is now being done in the tendency of the larger companies to continue as "going concerns," expending a certain amount of their capital in exploration here and there.

CONSOLIDATED GOLD FIELDS OF SOUTH AFRICA.

The directors of the Consolidated Gold Fields of South Africa, Ltd., announce that the realized net profit on the year's operations, which is largely derived from dividends received on investments, after deducting debenture interest and all outgoings, shows a balance to credit of £792,883, from which the dividend on the first preference shares, accrued dividend

on second preference shares, an interim dividend of 2s. per share on the ordinary shares and French Government taxes, have been provided, leaving £487,003, which, added to £79,485 brought forward, leaves £566,488. From this the directors have made provision to the extent of £100,000 for the further writing down of the prices at which investments in the shares of crushing mines stand in the books of the company, leaving £466,488 available for dividend. In addition to the foregoing realized profit, the company's share investments (apart from any appreciation in value on properties and ventures) show, on current market prices, a further large unrealized profit. Investments stand in the books at average cost or under, and all shares are taken into account at prices below those current at the date when the accounts were made up. Certain changes in investments were necessitated by the formation of the Rhodesian and American Development Companies and realizations have taken place in Russian and other assets; otherwise the changes that have taken place in the company's holdings during the past year have not materially affected the general position or the nature of the investments. The directors recommend that a final cash dividend of 15 per cent. and a bonus of 5 per cent., both free of income-tax, be paid on the 2,000,000 ordinary shares, amounting to £400,000, and making, with the interim dividend, 6s. per share for the year, leaving £66,488 to be carried forward.

MODDER'S CIRCULAR SHAFT.

At the meeting of the New Modderfontein Gold Mining Company, held at Johannesburg in September, the chairman made the following remarks regarding the new circular shaft: "The sinking of a new circular shaft, which is another important part of the expansion programme, is proceeding very satisfactorily. The whole of the sinking equipment has been completed, and the shaft has so far been sunk to a depth of 588 feet, at a cost which compares very favourably indeed with the cost of rectangular shafts sunk on these fields. This shaft is being put down at a steady rate and with economy, but we are not attempting to break any records in sinking or to hurry the work unduly. We expect that it should intersect the reef towards the end of next year, which will fit in admirably with our programme. I might add here that your consulting engineer, Mr. Stuart Martin, in recommending the sinking of a circular shaft, had in mind several important points that, in his opinion, make for its advantage over a rectangular shaft. There is first the cost of sinking, which should show a considerable decrease. Then the cost of maintenance should be appreciably lower, as the circular shaft is walled, and there should be, therefore, none of the many troubles with the timbering which we meet with so frequently in rectangular shafts. Further, there are the questions of rapid hauling and ventilation, both of which, it is considered, are facilitated."

Federal Commission to Investigate Mining

Following is an abstract of an article that appeared in the Nelson (B.C.) Daily News on November 22nd:

At one of the largest and most representative mining conventions ever held in British Columbia resolutions were passed here yesterday asking the federal government to appoint a commission to investigate thoroughly the various questions affecting the silver-lead-zinc industry and to create a separate portfolio of mines to be held by a minister who will devote his entire time to the work.

The meeting suggested to the government that the enquiry by the proposed commission might include the questions of a tariff on lead and zinc and the by-products of the two metals; of continuing the lead bounty at the expiration of the grant at present partly disposed of; of the granting of a bounty on zinc and of the offering of some reward to the person or persons inventing a process for the treatment on a commercial scale of the complex low grade ores of the Kootenays. Each of these suggestions found strong advocates at the convention, which was unanimously in favor of some form of protection for the industry.

A committee was appointed to investigate the carious questions affecting the industry in British Columbia. The chairman of this committee is W. E. Zwicky, who will be glad to receive suggestions in writing affecting the industry from all interested in the subject Such communications should be addressed to Kaslo.

Copies of the resolutions passed will be forwarded for an endorsation to the Conservative convention at New Westminster on Friday. As subjects for discussion he suggested the question of the continuance of the lead bounty; the present low duties on lead and zinc; the high United States tariff on the same metals further experiments toward the solution of the zinc problem, and the appointment of a federal commission to enquire into the various questions affecting the industry. He suggested the selection of delegates to present any resolutions which might be passed by the convention.

James Johnstone said that he thought the question of expense should not be considered by the government in carrying on further experiments toward the solution of the zinc problem. If it cost $300,000 or $400,000 it would be a profitable investment. He offered the following resolution:

"In view of the partial success which has attended the work done by Dr. Haanel in Ottawa and Montreal during the past year toward the solution of this most important problem and in view of the fact that the money set aside by the late government for this purpose was insufficient to bring the work to a successful conclusion, this meeting does hereby urge the Dominion government to set aside a sum of not less than $50,000 to be used for this purpose.

"And we do further recommend that an award of $25,000 be offered any individual or company who shall perfect any process on a working commercial basis for the separation of zinc ores as found in the mines of the Slocan and Nelson districts of British Columbia."

E. W. Widdowson seconded the resolution. He thought the prize of $25,000 should be awarded to any person solving the question, whether by a perfected old invention or a new.

Wants Tariff.

C. F. Caldwell thought that the greatest aid to the solution of the zinc problem would be adequate tariff

protection for the industry. By protection only could the permananency of the silver-lead-zinc industry be assured. Under present conditions the Canadian mine owner could not eompete with the American competitor. He expressed an abounding faith in the mines of British Columbia. The lead industry affected every person in the Dominion, he declared. Mr. Caldwell said that he pleaded not for the operating properties, but for the prospects and mines which were idle. He described the present conditions as unhealthy and tending to make the high grade properties pay for the low grade properties, which, he said, could only be operated at a profit by a big smelting company.

"It takes bulldog tenacity and unfaltering courage to make a success of mining. The man who knows how to quit is no good in mining," declared Mr. Caldwell, who sat down amidst applause after urging an enquiry into the question by a commission.

The idea of the late government in making the grant of $50,000, said L. B. Reynolds, was to obtain a knowledge of the research made into the metallurgy of zinc by private companies and inventors, but not made public.

Experiments Should Be Here.

J. P. Farrell said that the conditions of the mines of this district were peculiar to the Kootenays and that any experiments should be earried on in Nelson. Even in the Kootenays there were hundreds of different complications in the ores whieh varied to a remarkable degree frequently in different workings on the same vein. He advocated an adequate tariff on ores from the United States.

Urges Bounty on Zinc.

A. Gordon French told of what had been done in Australia toward the solution of the complex ore question. The problem was one of the most intricate and difficult problems in metallurgy. It was no problem for a student or for an entirely theoretical man. While in Ottawa, said Mr. French, he had been told that both Dr. Haanel and Dr. Ingalls had abandoned the problem.

Efforts to treat sulphide zinc ores with or without lead, by an electric heating process was a physical impossibility, declared Mr. French, who explained in technical terms his reasons for the statement.

With regard to the Nelson zinc plant, which was erected under his supervision, Mr. French said that the zinc was coming off every day. He would not, in any event, leave this country until he had completely solved the question on a eommercial scale.

He advoeated not only a bounty on lead but also a bounty on zinc. He thought there was a good market in Great Britain for all the zinc Canada could produce. Mr. French was not in favor of the offering of a prize by the government for the solution of the problem. If the bounty on zine was given it should be seen that the bounty was proportionately divided between the prospectors and the smelters, who stood at the two ends of the industry. For the next 50 years the market for zinc and zinc pigment in Canada would be a growing one, said Mr. French. Zinc white eould be produced very cheaply in this country. Another industry of importance which would grow out of the zinc industry was the manufaeture of galvanized iron, he said.

The cheapness of electric power for the electrolytic process of zinc treatment was a great advantage offered by Nelson to the prospective builder of zinc plants, Mr. French said.

Oscar V. White spoke of the low price realized under present conditions for zinc.

In reply to a question Mr. French explained that from the silver-lead-zinc ores by his process he obtained the zinc and forwarded the silver-lead residue to a lead smelter. Another product of the process was black manganese di-oxide, an extremely valuable commercial product.

Would Protect Canadian Industry.

I. W. Bingay, explained that some lead products, such as tea paper, red lead, both manufactured products which might be made in Canada, were imported into the Dominion every year. He thought the Canadian manufacturer should be protected. The proportion of a duty on pig lead involved the whole schedule, as the manufacturer who used the raw material must be protected. Whether a tariff would be better than a bounty was a very deep question which should be thoroughly investigated. He advocated the appointment of a strong committee to prepare a case for the proposed federal tariff commission. It was not true that the lead bounty had not proved of benefit to the industry.

T. G. Proctor thought that one of the most important matters to be brought before the federal government was the formation of a department of mines with a minister with a portfolio.

Bonus for Zinc Smelter.

A. J. Becker, as an amendment to Mr. Johnstone's motion, suggested that the government pay a bonus to a local smelter of $10 per ton of spelter produced up to 20,000 tons, or $200,000. The motion was seconded by J. J. Fingland. It was explained that the object of such a grant of $200,000 was to induce efforts to solve the problem. If there were several competitive smelters each was to receive the bonus as each ton of spelter was produced.

Should Sell Lead in Canada.

W. E. Zwicky thought that a protective tariff should be placed on lead and that a bounty be placed on zinc. This bounty, he said, should be divided between the producer and the smelter. Another point was that the Canadian producer should sell in Canada and not in free trade England. He urged that the government be asked to appoint a commission to go into the various questions affecting the industry.

M. Giegerich advocated a bounty on zinc and a tariff on lead.

Mr. Caldwell supported a duty on zinc, in order to build up a Canadian market, instead of a bounty.

C. A. Mackay was in favour of protection for lead and lead by-products. He thought a case should be prepared on general lines and presented to the government asking the appointment of a commission to investigate the questions of bonuses on land and zinc, the tariff and a bonus to encourage efforts toward the solution of the zinc problem.

Suggestions for Government.

I. G. Proctor, who took the chair during the temporary absence of Mr. Starkey, appointed, on the suggestion of H. Giergerich, R. H. Stewart, C. A. Mackay, and A. J. Becker a eommittee to draw up a resolution on general lines on the question. This committee brought down the following resolution, which passed:

"Whereas, there is at present no market available which will allow of the profitable mining and treat-

ment of zinc ores of Canada; therefore, be it resolved that:

"This convention of those interested in the mining of lead-zinc ores in southern British Columbia does strongly urge upon the government of the Dominion of Canada the neeessity for

(1) "The provision of adequate proteetion on zinc and zinc produets which shall lead to the establishment of zinc smelting or refining industries in the Dominion of Canada and enable the producers of zinc ores to market their ores profitably, whether by bounty on the spelter produced or by an adequate duty on zinc and zinc products imported into Canada, or by both;

(2) "That this convention urges that the Dominion government appoint a commission to enquire into the methods best suited to eneourage and proteet the said industry;

(3) "That the committee so appointed should consider the question of bonus or other reward to any individuals or companies who may devise and earry to commereial sueeess works for the reduetion and refining of the low grade zinc-lead ores of this eountry whieh are not at present amendable to the ordinary methods of zinc reduetion;

(4) "That the eommission should eonsider whether it is advisable to assist finaneially any person engaged in the working out of sueh process, provided such an experimental work shall show promise of being successful;

(5) "That eopies of this resolution be forwarded to the Conservative eonvention to be held in New Westminster on November 24; to the honouroable the Minister of Mines at Ottawa, and to Mr. A. S. Goodeve, member for Kootenay."

Investigation Committee.

The following resolutions were also passed:

"Whereas, the present lead bounty has been of very considerable benefit to the lead mining industry; and

"Whereas, said bounty will expire on June 30, 1913; and

"Whereas, the Dominion government has stated its intention to appoint a permanent tariff commission; and

"Whereas, we, the assembled representatives of the mining industry, eonsider it advisable to petition for protection on lead and zinc, either in the shape of duty or bounty;

"Resolved, that this meeting elect a committee of six to investigate the situation, and to bring it to the attenion of this commission; and also o ask the endorsation of the above by the British Columbia Conservative Association whieh meets at New Westminster on 24th November, 1911." This was moved by O V. White, and seconded by James Anderson.

The committee appointed is W. E. Zwieky, O. V. White, A. J. Becker, F. A. Starkey, T. W. Bingay, and R. F. Green.

To Create Portfolio of Mines.

It was moved by W. B. Farris and seeonded by James Johnstone, that the federal government be asked to create a portfolio of mines, the minister to devote his attention entirely to the industry.

A resolution urging the Dominion Government to appoint a eommission to investigate in Kootenay the questions relating to the industry at the earliest possible date was moved by H. Giegerich, and seconded by James Anderson, and carried.

T. G. Proctor moved that the government be requested to inform the public what has been the result of the past year's zinc experiments. The resolution was seconded by W. E. Zwieky, and carried.

Votes of thanks were passed to Mr. Starkey for calling the convention, and to Mr. Beeston for acting as seeretary.

In the month of September last there were 10,341 stamps and 241 tube mills in commission in the Transvaal. The total output of gold was 700,023 ounees, valued at £2,973,511.

At the Robinson Deep mine, on the Rand, the cost of ore broken during the month of August last was 6s. 0.3d. per ton where machines were used, and 6s. 11.5d. per ton with "hammer boys." The stopes ranged from 51.1 inches (handwork), to 59.9 inches (large maehines).

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Glace Bay: Dominion Coal Outputs, 1911 Season.

The shipping season of 1911 has been a very successful one, and a comparison with previous seasons will show the advance in output capacity which the Coal Company's mines have made. The production for the period between the 1st of May and the 30th of November has been as follows, from 1906 onwards:

May-November, 1906	2,281,884	tons.
May-November, 1907	2,262,850	tons.
May-November, 1908	2,129,944	tons.
May-November, 1909	1,567,043	tons.
May-November, 1910	2,363,970	tons.
May-November, 1911	2,480,000	tons.

The 1911 season shows an average monthly output of 354,000 tons, a figure which is 18,000 tons greater than any previous average obtained during the shipping season.

The shipments to St. Lawrence ports were also larger than ever before, as may be seen from the figures following:

Shipments to Montreal and St. Lawrence ports.

Season 1906	1,126,387	tons.
Season 1907	1,038,500	tons.
Season 1908	1,311,490	tons.
Season 1909	828,446	tons.
Season 1910	1,146,300	tons.
Season 1911	1,420,000	tons.

It will be seen that the St. Lawrence shipments are 110,000 tons greater than 1908, a year which broke all previous records.

ıs the Coal Company's profits depend very largely on the quanity of coal which can be mined and shipped in the season f open navigation, the operations of the season just closing hould have a favourable effect on earnings.

Mr. Richard Kirkby, who has for the last three years filled he position of mining engineer to the Dominion Coal Company, has resigned and returned to his home in Scotland. Previous to Mr. Kirkby's departure the members of the South ape Breton Mining Society tendered him a complimentary ddress, and presented him with a gold watch. It is generally egretted that Mr. Kirkby should have found it necessary, or purely personal reasons, to leave Cape Breton, where he ad proved himself a capable mining engineer and a tactful fficial.

The Baum Wash Plant, which has been under construction t Sydney since the spring, is now well advanced, and all the utside and concrete work is finished. The machinery is on ıe ground, and it is confidently anticipated that the Wash lant will be in full working operation by next June.

The railway branch to the Birch Grove Collieries is completed as far as the site of No. 21 Colliery, and the work of ecting the bankhead is commenced. The electric power transission line is also completed from No. 2 Power House to No. 1 Colliery. Contracts have been let for the building of a umber of miners' and officials' dwellings at Birch Grove, hich it is hoped to complete before the spring.

Over 300 dwellings have been completed this summer at ıe Lingan Collieries, and contracts have been let for additional houses to be ready by the spring. A large hotel is also eing erected by the company, for the accommodation of single en.

pringhill Mines.

Mr. J. R. Sharpe, who was the manager of the Cumberland oal & Railway Company's mines at the time they were abrbed by the Dominion Coal Company, and has since been cting as district superintendent, has resigned his position. Mr. D. Maxwell has been appointed resident superintendent, the ppointment being effective on the 15th November. Mr. Maxell has been manager of several of the Coal Company's ines, and has recently acted as assistant to the mining engier. It is understood that Mr. Sharpe has taken a position the States.

ort au Port, Newfoundland.

A large amount of work is now being done by the Dominion on & Steel Company at their new limestone property in ort au Port Bay, Newfoundland. It is expected to have a lly equipped and producing quarry at Port An Port for next eason's limestone requirements. The Steel Company's conmption of limestone is very rapidly growing.

ational Safety Field Day at Pittsburg.

The National Safety Field Day at Pittsburg on the 30th of ctober, appears to have been an unqualified success. The perintendent of the Dominion Coal Company's Rescue Staon was present, and reports that representatives from all over e North American continent were gathered from points as stant as Seattle and the Canadian West, Alabama, and the olated coalfield of Cape Breton. Every courtesy appears to ve been shown by the officials of the U. S. Bureau of Mines the Canadian visitors, and no restrictions were placed on e information available. The explosion of the experimental ine at Bruceton by black powder fired into coal dust was out as convincing a demonstration of the possibilities of a st explosion as one could wish to see, and if it struck a holesome terror into those persons who deny the possibility dust explosions without the presence of gas, it will have served a useful purpose. It is said the mine before the explosion was so humid as to be almost at the saturation point, but nevertheless the explosion took place. The Mines Bureau, it is understood, are going to issue an account of the experiments conducted in the form of a Miners' Circular, which will be well worth reading. The publications of the U. S. Bureau of Mines now form a valuable series of reports and monographs, which, thanks to the courtesy of the U. S. Government, can be obtained by any Canadian who desires to use them.

Dr. Shields, the genial and energetic head of the Red Cross work in the U. S. mining districts, was also very ready to devote his time to giving information to the Canadian delegates. In this matter of first aid and ambulance training, the mining men of the States, although possibly tardy in recognizing the usefulness of such instruction, have taken hold in a manner typical of the American, and the greatest enthusiasm is being displayed at the present time. The progress of the work has in the past been greatly hindered by strike troubles, as was the case in the mining towns around Glace Bay, and it has taken some time to gain the ground which was lost. It is to be hoped that the threatened labour troubles for next spring in the Pennsylvania mines will not once again undo the work that has taken so long to do.

ONTARIO.

Cobalt and Gowganda.

After lengthy trials, the Nipissing Mining Company has decided to build a concentrator. It will have a capacity of 200 tons and is to cost $250,000. The various shafts of the big mine will be connected by an aerial tramway, which will pass over the lake. The cyanide process will be used. The mill will be built on Nipissing Hill and work on the excavations has already begun.

Since the meeting of the La Rose directors three important developments have occurred at the Lawson, the Fisher Eplett, and the Princess. At the Fisher Eplett a foot wide vein of quartz and calcite has been uncovered in which can be seen at various points patches of high grade ore. As the productive veins on the Beaver and the Temiskaming, adjoining mines, showed no ore of value at the surface, sinking operations will commence at once and will be pushed with vigour all winter. At the Lawson in an intermediate level an extension of the rich No. 8 vein has been encountered. It is now providing some of the richest ore ever found at the mine, and for 30 feet has averaged six inches wide. At the Princess a two-inch but very rich vein has been cut up in the stope from the 135-foot level, and also on the 135-foot level itself.

This month the Cobalt Provincial mine has shipped a car of 1,200 ounce ore taken from the stope at the 100-foot level. In the winze below the 200-foot level the ore has come into the vein again unexpectedly, and this new development in part counteracts the disappointment of not finding values in the Savage veins when they were cut.

Operating profits at the La Rose mine for the month of September amounted to $94,779. During the month there were produced 313,501 ounces, having a gross value of $164,000. The production for the first nine months of the year shows that 2,751,946 ounces have been mined, while total expenses amounted to $536,868, leaving a profit of $916,765.

Porcupine, Swastika, and Other Gold Areas.

It has been officially announced that the stamps in the Dome mill will commence to drop on January 15th, unless unusually severe weather is encountered and other unexpected and abnormal difficulties. It is generally believed in camp that even with the Dome's superb organization it will tax its

powers to the utmost to carry out the undertaking in so short a time. The most spectacular streak in the Golden Stairways will be lifted out and sent down to the Parliament Buildings at Toronto as an exhibit. A shaft is now being sunk to crosscut this vein at 100-foot levels. It has already been ascertained by means of the diamond drill that the ore body does go down several hundred feet, and the shaft will be put down to the 400-foot level before any systematic attempt is made to block out ore. Owing to the very resolute manner in which the reconstruction of the mill has been pushed, it is probable that for the first two or three months the mill will be ahead of the mine. During the first month only $6 ore will be run over the plates, so that in the event of any adjustments as little loss will be incurred as possible.

It is stated that diamond drilling operations have been attended with the greatest success; what was hoped before has now been proven. In all, eighteen holes have been put down and average 800 feet to the hole, and an area of almost a thousand feet has been covered.

The staff has at length been enabled to move into the new camp buildings out of the tents which have been occupied ever since the fire.

The Temiskaming Mining Company, of Cobalt, has acquired a controlling interest in the North Dome mine from C. S. Beardsley, of Cleveland; P. Kirkegaard, and the North Dome Company. Bert Wolfram will succeed Chris Nelson as mine captain in the Temiskaming mine interests, and it is expected that a very vigorous campaign of development will be undertaken this winter. On the surface the veins appear as small and rich, but when the conglomerate capping is removed they open out to considerable ore bodies rich in sulphides and showing here and there free gold. So far little work has been done underground since the fire. A compressor adequate for the development of the mine is on the ground, but has not as yet been set up.

So satisfactory has been the development of the Deloro claims of the Dobie Mining Company that two shafts will be sunk at once on the vein to discover what there is below. The ore on the surface is quite spectacular.

A prospector named W. Milton Yorke, states that there are good showings in quartz veins on the Hurricanaw River about 75 miles to the north of the Transcontinental Railway. The Transcontinental Railroad is left at a point 150 miles east of Cochrane. Until the river freezes over solidly the trail is impracticable.

Twenty-one dividends have now been paid by the Crown Reserve, making a total of $3,626,061 to date, or 215 per cent. on capitalization. A dividend of $88,440 is paid monthly.

The new Pullman service to Porcupine will come into effect in the first or second week of December. The terminus for the present will be South Porcupine, but as the steel is laid, the rock cut finished round Pearl Lake, and the new bridge over Pearl Lake built, it will be moved south to the Timmins townsite. For the present two switches will be laid for the convenience of those mines wanting to get in machinery at once. There will be an enormous rush of supplies to this point directly they are laid.

At the 100-foot level and about 50 feet from the shaft, the Davidson vein has been cut by the Crown Chartered, who now has the property. So far the hanging wall of the vein has not been reached, though 30 feet of quartz and schist have been run through. It is probable that in a few weeks Consulting Engineer R. B. Lamb will make a report, and this will be eagerly awaited.

The new ten stamp mill at the McIntyre has been ordered. Until further tests have been made as to the nature of the ore it is not proposed to instal the cyanide treatment. The Vipond mill has also been ordered and will be installed without delay. Crosscuts are now being run on the Vipond to cut the No. 2 vein at the 200-foot level, and also to catch it at two points on the 100-foot level. Until the big compressor is installed only one drill is available, and progress is necessarily slow.

The American Eagle Mining Company in Munro township has just shipped two 50-ounce bricks of gold to New York. Earlier in the year the Gold Pyramid shipped 70 ounces, so that the record for Munro township for this year is already 170 ounces. Both these mines have small mills and have been working some time.

At the 300-foot level the Rea Consolidated mines have forty feet of almost solid quartz in their vein. At the 200-foot level it averaged between four and six feet wide. Some time ago above the 200-foot level ore blocked out on four sides was reckoned at $280,000. Since then the 300-foot level has been reached and the vein found to be much wider than at any other point in the mine. Also, on the surface another lead has been found to outcrop for several hundred feet, showing free gold at various points.

On the Lucky Cross property at Swastika the new compressor has been started and work at the new shaft will now be pushed forward at a much more rapid pace than formerly, when only hand steel work was possible.

This week the 20 stamps at the Dr. Reddick mill commenced to drop again. The only other property to resume work on any scale in the Larder Lake field is the Goldfields, which now has the Harris Maxwell, the Proprietary, and the old Indian. There is stated to be a quantity of $10 ore above the 80 foot level at the Dr. Reddick which will be milled right away. The Harris Maxwell is at present confined to putting in an electrical power plant to develop the various properties.

The Dixie syndicate, holding the Newman Mancha Johnston claims in Deloro has sold its interest to a Toronto and Boston syndicate, who will float a three million dollar company and start to develop forthwith.

BRITISH COLUMBIA.

About the middle of November announcement was made to the effect that the negotiations between representatives of the Western Coal Operators' Association and District No. 18, United Mine Workers of America, respectively, had been completed and that the proposed agreement between the parties would shortly be submitted to the coal miners and other employees in the several districts concerned for their ratification, this referendum to be carried through with as little delay as possible. It was stated that an agreement had been reached upon most of the matters regarding which there had been differences of opinion, an exception having been that of the minimum wage to be paid to workers, which question is to be arbitrated later. It is hoped, therefore, that work will be resumed in the larger mines before the end of November. There is little probability, though, of there being any considerable quantity of coal produced during the few remaining weeks of the current year.

East Kootenay.—The Sullivan mine, situated near Marysville, is now the largest producer of lead ore in British Columbia. Its output for the expired eleven months of the year has reached a total of between 16,000 and 17,000 tons, which quantity has been shipped to the Consolidated M. and S. Company's smeltery at Trail. There is available in this mine a very large tonnage of ore, but much of it has a zinc content, as well as lead, which makes it unsuitable for reduction under similar conditions to those admitting of the profitable utiliza-

tion of ore in which lead is the chief constituent. Whenever it shall be found practicable to treat the zinc ore at a profit, there will be developed here one of the largest zinc-lead mines in Canada.

Ainsworth—The Consolidated M. and S. Company has arranged for the acquirement of the No. 1 mine, situated in Ainsworth camp. This mine has for some years been worked on a small scale by Mr. H. Giegerich and associates, and though its output of marketable ore has not been large, it has generally paid working expenses. There appears to be a prospect of work being resumed at the Blue Bell mine, across Kootenay Lake from the town of Ainsworth. A proposal to again operate the mine and concentrating mill has lately been having the consideration of the directors of the company, the headquarters of which is in Europe, but at the time of writing no advice has been received of their decision, if yet arrived at. In another part of Ainsworth mining division, some 12 to 15 miles from Kaslo, up the line of the old Kaslo & Slocan Railway, is situated the Utica, a property stated to promise a large tonnage of ore, whenever arrangements shall have been made for working it continuously and milling facilities shall have been provided for concentrating that part of the ore not of sufficiently high grade for shipment to the smeltery in its crude state. Mr. Chas. F. Caldwell is endeavouring to obtain the amount of money requisite for placing the Utica on a permanent milling and shipping basis.

Nelson Division.—In Nelson mining division, the Granite-Poorman gold mines, five miles west of the city of Nelson; the Molly Gibson silver-lead mine, at the head of Kokanee Creek, about 20 miles in the opposite direction; the Emerald lead mine, in the vicinity of Salmo, and the Queen gold mine, in Sheep Creek camp, are the chief producers of ore as the year draws to its close. Several other properties, in different parts of this division, are also being worked, but in some cases with only a small output being maintained or with development work being carried out and no ore being mined. On the whole the year's production of metals has been less than was expected it would be, yet since substantial progress has been made in the direction of providing for an increased output in the future, the situation is not unsatisfactory.

Rossland.—The Consolidated Mining and Smelting Company's Centre Star group is keeping up its output, which will probably be for the calendar year 1911 about as much as for the company's fiscal year to June 30, last, namely, 193,000 tons. Litle publicity is being given to information indicating the conditions prevailing at these mines, but it is understood in the camp that the War Eagle mine, especially, is looking well, much ore containing a comparatively high gold value having been found, while other mines of the group, including the Le Roi, which has been added, are contributing materially to the generally good results that are being obtained from these mines as a whole. The Le Roi No. 2, Limited, is also making gratifying progress, recent deep-level developments having proved the existence in the lower levels of the Josie mine of considerable quantities of ore of good grade. The general average value of the ore extracted from the mines of the Le Roi No. 2, Ltd., continues to keep up well, being closer to that of earlier years. The year's production will show a total of about 45,000 tons of ore, of which about three-fifths will have been shipped to Trail as crude ore and the remainder put through the company's concentrating plant at the mine with results that add appreciably to the profit-earning capacity of the mine.

Slocan City.—While there is not nearly so much activity in the several camps in mining in Slocan City mining division as in some other parts of the Slocan district, mining is being carried on in several camps. On Ten-mile Creek, both the Enterprise and the Ellis Silver Mining Company's Eastmont mine are being worked. In the former the ore developed during recent months is not of so high a grade as it was expected would be found in the lower levels opened latterly, but it is hoped there will be an improvement in this respect before long. No information has been obtained of late as to progress at the Eastmont, but it is known work is still being carried on, and preparations were being made early in November to haul ore to the landing on Slocan Lake, for shipment thence to Trail. Other properties on which work was being done are the Lily B. and Meteor, both situated in the vicinity of Springer Creek. Shaft-sinking constitutes the development work in hand on the former claim. In the past the Meteor has been a shipper of high-grade silver ore, and it is expected it will continue to make a production of a similar class of ore.

Trout Lake Division.—On the Winslow, a gold claim situated a few miles from Trout Lake, Mr. Bruce White has driven a tunnel between 200 and 300 feet, and has cut a gold-bearing vein. Recently work was stopped for the winter, snow being deep in the locality during winter months, but next spring development will be undertaken on this property. The Silver Cup, in Ferguson Camp, continues to make shipment of high-grade ore to Trail, though its tonnage for this year has fallen somewhat short of that of several earlier years. Little else in mining has been reported from this part of West Kootenay, notwithstanding that there are many good showings of ore that appear to be well worth developing.

Golden Division. — The Vanvoucer organization that, under the name of the Mt. Stephen Mining Syndicate, is operating the old Monarch mine, near Field, on the main transcontinental line of the Canadian Pacific Railway Company, has done much development work, and made many surface improvements, the latter including the erection and equipment of a concentrating mill, putting in a pipe line to convey water to a Pelton wheel for operating mill machinery, and a compressor, installation of an auxiliary steam power plant for use when water power shall not be available, erection of an aerial tramway and establishment of a telephone system, from mine to mill, and building houses for the accommodation of miners, etc. Much underground work has also been done to develop the big body of lead ore occurring here. Altogether considerable activity has been shown, and the prospects are that the old Monarch mine will next year become productive to a degree that will show the enterprise and confidence of the syndicate to have been well warranted.

Boundary.—The Argo Mining and Tunnel Company, of Greenwood, is driving a 6 by 7-foot tunnel to cut several veins outcropping on the surface of the hill, more than 300 feet above the present face of this adit. It is believed that one of the bigger veins will shortly be cut. It is proposed to continue driving until a distance of 1,000 feet from the portal shall have been reached, by which time the face of the tunnel will be about 600 feet below the surface. Thus far only stringers of ore have been cut, but it has been known all along that it would be necessary to drive more than 600 feet before the first of the larger veins could be reached. The work is being continued with the expectation of soon reaching ore in quantity.

Similkameen.—The British Columbia Copper Company has commenced prospecting work on the large group of mineral claims in Voigt's camp, Copper Mountain, near Princeton, described in the Canadian Mining Journal of August 1 (p. 493). A newspaper story to the effect that the price agreed upon should this property be purchased under the bond, is $2,000,000 is a flight of imagination, as is also the statement that other expenditure provided for will bring the total up to $3,000,000. The price named in the bond is only about one-fifth of $2,000,000, while but a limited amount has been appropriated for prospecting and development work. If sufficiently encouraging results shall be obtained, most likely development work will be continued, but not otherwise.

Coast District.—The most important metal mining in progress in the Coast district is that at the Britannia Mining and Smelting Company's Britannia mine, in New Westminster mining division, and the further exploitation of the Hidden Creek group, by the Granby Consolidated M. and S. Company. During the autumn up to more than 300 men were employed on the Britannia, and within 50 or 60 of that number at Hidden Creek. Coal mining developments on Vancouver Island are also important. Information from Hazelton district, Skeena River, indicates the opening of promising shoots of silver-lead ore there.

GENERAL MINING NEWS.

ONTARIO.

[Editor's Note.—The following is editorial comment that was written too late to insert in the proper column. It is none the less important. If any of our readers think that we have been unfair we shall be glad to hear from them.]

Toronto, Nov. 24.—There appeared in the Toronto Globe of this date certain extracts from an article in The Boston Commercial. Mr. George L. Walker, the editor of The Commercial, is the author of the article, and his subject is Porcupine.

From his own account Mr. Walker went to Porcupine to find out whether the camp is or is not a bubble. The net result of his visit was that he came away satisfied that Porcupine has a "big future." A few sentences here will show the tenor of Mr. Walker's remarks.

He points out that for work done there are surprisingly many gold showings of commercial value. Diamond drills have disclosed "free gold" (by which is meant "visible gold") to a depth of 800 feet. He refers to the Dome as having several million dollars of "profits demonstrated"; and to the Hollinger as having about 100,000 tons of ore actually in sight.

Both of these statements are undigested. There is no room for guessing and less cause for knowing that the Dome has some millions of dollars in profits developed. In fact, the Dome management has made public nothing to indicate this. Moreover, the Hollinger, if we may gather anything from the announcements of its directorate, has much more than 100,000 tons in sight. To put it briefly, there is no more foundation for Mr. Walker's conclusions than there is for the wildest vision of the cub reporter.

But with Mr. Walker's strictures on financial and promotion methods we are fully in accord. After scoring the futile schemes of floating the average "claim," he expresses the belief that Porcupine's future depends upon underground exploration, and upon the development of large tonnages of ore that will yield from $1 to $3 net profit. Porcupine, to succeed, must be organized much more conservatively. Working capital must be enlarged, and promoters' first profits must be cut down.

Mr. Walker's remarks would have been immeasurably stronger if he had left out specific references that weaken his argument, and tend to throw discredit upon his ability to observe without bias.

Ottawa, Nov. 22—The first organized demand for higher protection for the vested interests was presented to the Government to-day by the representatives of all the steel and iron companies in Canada. The conference lasted over two hours. The companies applied for a renewal of the bounties on pig iron as a provisional expedient to be effective until the tariff could be revised.

The discussion was almost entirely confined to this application. The question of aid by bounty to steel rods will be dealt with at another time.

The Government gave the steel men a sympathetic hearing and asked for statistical information. The members of the Government who heard the deputation were: Premier Borden, Finance Minister White, Minister of Customs Reid, Minister of Trade and Commerce Foster, Minister of Railways Cochrane, and Postmaster-General Pelletier.

Among the men on the delegation and the companies represented were J. H. Plummer, of the Dominion Steel; T. Cantley, of the Nova Scotia Steel; T. J. Drummond, of the Soo Company: Cyrus Birge, of the Steel Company of Canada, Hamilton; R. Hobson, and R. J. Mercure, representing the Deseronto Blast Furnace and the Atikokan Iron Company.

The Government was urged to take up the whole case of the iron and steel industry in Canada, and after thorough consideration to give it the aid by bounty or tariff protection to which it was found to be entitled. The steel men assured the Government that the industry in Canada to-day is at a disadvantage, compared with its competitors in other countries. There should be something done before an examination of the situation could be made. To relieve the immediate situation it was urged that there should be a restoration of the bounty on pig iron.

While the Government gave the steel men no promise beyond careful consideration of their application, the general belief is that something will be done. That is the feeling which the steel men have themselves, and it is shared by most members of Parliament.

QUEBEC.

Mr. R. M. Aitken, of the London house of Kilcat & Aitken, arrived in Montreal on November 20th, in connection with the contemplated reorganization of Amalgamated Asbestos.

"We hope," he said, "to get matters in such shape that the representatives of the bondholders will soon be able to get together and discuss plans for the future welfare of the company. I feel sure that the American, Canadian, and English representatives, when they meet to talk things over, will be able to work in harmony and will decide upon an arrangement that will put the company upon its feet again."

Montreal, Nov. 20.—One of the most important meetings ever held by the directors of the Dominion Steel Corporation was held this afternoon at the Bank of Commerce. The president, Mr. J. H. Plummer, occupied the chair, and the directors present were: Sir William Mackenzie, Sir Montagu Allan, William McMaster, George Caverhill, Sir Henry Pellatt, Senator Cox, Senator MacKay, Senator Dandurand, J. R. Silson, W. D. Matthews, and F. L. Wanklyn.

After the meeting the following official statement was given out: "The chief subject considered by the Board of the Steel Corporation to-day was the recommendation of the president that the Steel Company should not continue to provide for the expenditure on its new plant by the sale of bonds, which were

authorized in 1909, of which about $6,000,000 is still held in the treasury, but that capital should be obtained by the issue of preferred stock of the Corporation.

"The Coal Company has also entered upon important extensions, which will increase its fourteen producing collieries to twenty, and require greater facilities for transportation, etc. The capital required by that company can also be obtained through the Corporation.

"The advantage of this means of financing is that it avoids the increase of fixed charges and leaves the Steel Company with a large reserve of unissued bonds of established market value. Nothing definite was done with regard to making the issue, but the board decided that, under proper conditions, this would be the best method of obtaining capital for the building of the various plants. Its ultimate effect would be to interest people in London, and probably in Paris also, in the stocks of the Corporation, and it would put the latter in a position to take care of the future capital requirements of the subsidiary Company on good terms.

"Provision will be made for the exchange in due course of the preferred stock of the Coal and Steel Companies for the Corporation preferred, on an equitable basis; with an established market for the new security in Europe. Such an exchange would benefit the present holders.

"The Company has been asked to give certain rights as to common stock in connection with the sale of the new preferred. Whenever that point may be reached it is not unlikely that this may lead to considerable investments in the common stock abroad. In any case, it is the interests of the common stock holders which the Board have most in mind. The whole object of the policy of extension, which is being vigorously pursued, is to increase output, decrease cost, and enlarge profits. The benefit of this, after payment of interest on the new capital, necessarily accrues to the common stock holders.

"Whether it is better to get the capital needed to enlarge the works by continuing to sell bonds, or to initiate a financial policy which will serve for future growth, as well as for present needs, and make those who supply the capital partners, instead of creditors, is purely a question of judgment; the object is to get capital for the new works on the most favourable terms.

"The new policy is most strongly supported by those who have the largest interest in the common stock, and was adopted by the Board without a dissenting voice."

BRITISH COLUMBIA.

Fernie.—The stupendous sum of $4,400,000, it is estimated by Mr. Elias Rogers, president of the Crow's Nest Pass Coal Company, who paid a brief visit to Victoria recently, was lost to the men in wages as a result of the strike which, after extending over many months, is just reaching a conclusion, more or less satisfactory to both parties.

Mr. Rogers said: "Our company has been paying out approximately an average of nearly eight thousand dollars less every day since April 1st than we were a year ago during the same period, and I think on all the mines affected the reduction in wages would be equal to about $20,000 per day."

Fernie.—There will be an increase in the price of coal from the mines concerned in the strike in the Crow's Nest Pass and Alberta when a settlement has been reached, and fuel from the properties now closed down again commences to reach the city, according to an opinion expressed last night by a local coal merchant.

The increase, he believed, would be about equal to the increase in the rate of wages granted to the miners under the settlement, which will mean that Galt coal, which previous to April 1st last cost $8.25 per ton here, will be sold at $9 per ton. The increase in the prices of other coals from the present strike area will, it is said, increase proportionately.

At present a large proportion of the coal being consumed in Nelson comes from Wyoming. It sells at $8.75 per ton. Coal from Vancouver Island, Princeton, and Pennsylvania is also being used by local consumers. Prices range from about $8 for Princeton coal to about $16 for the eastern fuel.

Fernie.—The large force of special police which has been assembled here for the protection of miners who want to work at Coal Creek were out in force this afternoon to meet the mine train which came down at 4 o'clock with the four Barrs, who returned to work this morning.

Sergt. Tucker and 15 mounted men and 20 foot policemen lined up and the four men were escorted to their homes, without being disturbed except by the derision expressed by the large crowd of miners who turned out to greet them. Chief Inspector Campbell, Chief Constable Minty, and City Chief Bowen were also present, and the force was well arranged and well handled.

The trial of Sweeny, charged with intimidating Alex. Barr on October 31st, was concluded this afternoon, but Magistrate Whimster reserved judgment until next Monday in order that he may have time to go over the transcript of the evidence. George Linn will come up for trial on a similar charge next Monday.

Nothing has been heard from Frank to-day regarding the progress of the work engaging the attention of the joint scale committee.

Nelson.—Bob Mabry, of Spokane, yesterday closed mining deals aggregating $140,000, purchasing the Yankee Girl for $100,000 from John Frazer, acting on behalf of the creditors, in addition to the Bi-metallic and the Lost Cabin group, all the properties being near Ymir.

He has already 15 men working at the Yankee Girl, three at the Bi-metallic, and six at the Lost Cabin group, and is restoring the cabins and workhouses at the Nelly B. mine, as well as continuing the sinking of the double compartment shaft of the last named, which is down 55 feet.

He said that over $400,000 worth of ore is ready to be mined at the Yankee Girl, and a flume is being built for generating compressed air.

At the Yankee Girl and Bi-metallic, on account of there being two feet of snow at Ymir and three feet at the mines, the work is being carried on under difficulties. At both the Bi-metallic and the Lost Cabin group tunnels are being driven to crosscut the ore.

STATISTICS AND RETURNS

COBALT ORE SHIPMENTS.

Following are the shipments from the Cobalt camp for the week ending Nov. 17, and those from Jan. 1, 1911, to date:—

	Nov. 17. Ore in lbs.	Since Jan. 1. Ore in lbs.
Badger	.....	55,200
Bailey	.....	40,000
Beaver	.....	1,520,217
Buffalo	55,161	3,328,024
Chambers-Ferland	64,000	1,214,900
City of Cobalt	.....	727,980
Cobalt Lake	.....	3,760,920
Cobalt Townsite	.....	1,189,881
Colonial	.....	183,410
Coniagas	40,893	3,661,380
Crown Reserve	46,769	2,049,829
Drummond	60,000	1,140,000
Green-Meehan	.....	146,800
Hargraves	.....	161,100

LA ROSE IN OCTOBER.

La Rose mine in October made a net profit of $75,500. The October production was rather larger than usual, being 255,800 ounces, the gross value of which was $136,000. The October income was $141,000, and the total expenses $65,500. La Rose is evidently looking to make a record before the end of the year.

TORONTO MARKETS.

Nov. 20.—(Quotations from Canada Metal Co., Toronto):

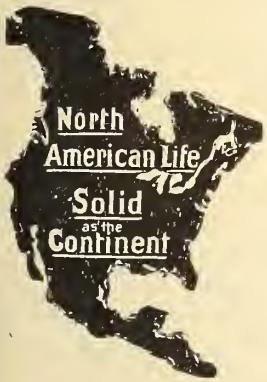
GENERATORS and MOTORS FOR ALL PURPOSES



A Man's Value

to his family or those dependent upon him is measured by his earning capacity. As death entails the loss of that earning capacity, every man should make provision for his loved ones in order to make good to them the financial loss that would ensue. This is the purpose of life insurance, and no man is blameless whose life is not insured.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining ngineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show ns of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a rough knowledge of Mining Law, should be very careful with whom they place their business.

WANTED---
Engineer, for Bituminous Colliery Development, Edmonton District, Alberta. Must be good Surveyor with experience in pitching seams, and well up in the design of Colliery plant buildings, etc. Only thoroughly capable men need apply. State age, qualifications, experience and salary expected. References required.
Apply in first instance to
Box 5, Canadian Mining Journal.

MINE MANAGER
and Superintendent, 38 years of age, with good experience as Manager, Superintendent, Mine Foreman, and Mine Surveyor seeks position. 10 years in Canada.
Address:—
"Miner"
Canadian Mining Journal.

DEPARTMENT OF MINES. GEOLOGICAL SURVEY.

PUBLICATIONS

The Geological Survey has published maps and reports dealing with a large part of Canada, with many local areas and special subjects.

A catalogue of publications will be sent free to any applicant. A single copy of a map or report that is specially desired will be sent to a Canadian applicant free of cost and to others at a nominal price. The applicant should state definitely the precise area concerning which information is desired, and it is often of assistance in filling an order for a map or report if he states the use for which it is required.

Most of the older reports are out of print, but they may usually be found in public libraries, libraries of the Canadian Mining Institute, etc.

REPORTS RECENTLY ISSUED:

CANADA

1085. Descriptive Sketch of the Geology and Economic Minerals of Canada. Accompanied by a geological and mineral map of Canada, by G. A. Young and R. W. Brock.
1170. Summary Report of the Geological Survey for 1910.

NEW BRUNSWICK and NOVA SCOTIA

1113. Memoir No. 16. The Clay and Shale Deposits of Nova Scotia and portions of New Brunswick, by H. Ries and J. Keele.

QUEBEC

1110. Memoir No. 4. Geological reconnaissance along the line of the National Transcontinental Railway in Western Quebec, by W. J. Wilson, accompanied by a map.
1064. Geology of an area adjoining the east side of Lake Timiskaming, by Morley E. Wilson.

ONTARIO

1091. Memoir No. 1, Geology of the Nipigon Basin, Ontario, by A. W. G. Wilson.
1137. Memoir No. 10 An instrumental survey of the shore-lines of the extinct lakes Algonquin and Nipissing in South-western Ontario, by J. W. Goldthwaite.

NORTH WEST PROVINCES

1115. Memoir No. 8. The Edmonton Coal Field, Alberta, with maps, by D. B. Dowling.

BRITISH COLUMBIA

1139. Memoir 11-T Triangulation and Spirit Levelling of Vancouver Island, 1909, by R. H. Chapman.

YUKON and NORTH WEST TERRITORIES

1080. Report on a part of the North West Territories drained by the Winisk and Attawapiskat Rivers, by Wm. McInnes.
1006. Report on a traverse through the southern part of the North West Territories from Lac Seul to Cat Lake in 1902, by A. W. G. Wilson.
1130. Memoir No. 9. Bighorn Coal Basin, Alberta. by G. S. Malloch, accompanied by a map.

1164. Map 28 A. Sketch map of Portland Canal Mining District.

YUKON and NORTH WEST TERRITORIES

1089. Map 9A. Explored Routes on Parts of the Albany, Severn and Winisk Rivers. Scale 8 miles to 1 inch.

NOTE.—Maps published within the last two years may be had, printed on linen for field use. A charge of 10 cents is made for maps on linen.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon. Letters and samples that are of a Departmental nature, addressed to the Director may be mailed O.H.M.S. free of postage.

Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.

BRITISH COLUMBIA

The Mineral Province of Western Canada

Has produced Minerals valued as follows: Placer Gold, $71,213,103; Lode Gold, $60,811,067; Silver, $31,095,602; Lead, $24,645,605; Copper, $60,743,405; Other Metals (Iron, Zinc, etc.), $1,083,172; Coal and Coke, $114,012,596: Building Stone, Brick, etc., $10,593,100; making its Mineral Production at the end of 1910 show an

Aggregate Value of $374,197,650.

In 1910 the quantity of Ore mined was 2,216,428 tons, and of coal 3,139,235 long tons. The value of Minerals produced that year was: Placer Gold, $540,000; Lode Gold, $5,533,386; Silver, $1,245,016; Lead, $1,386,350; copper, $4,871,512; Coal and Coke, $11,108,335; Other Minerals, $1,692,473, making the

Total Value for 1910, $26,377,066.

Lode mining has only been in progress for about eighteen years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those in any other Province in the Dominion, or any Colony in the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with mining Reports and Maps, may be obtained gratis by addressing

THE HON. THE MINISTER OF MINES
VICTORIA, B. C.

The MCKIERNAN-TERRY CLASS "B" HAMMER DRILL

"Three "Busy Bees" at work on the New York Subway Excavation."

Are you sinking a shaft?
Would you like to do it cheaper and faster?

If so, follow the method used by the contractors in New York, who are putting down the big shafts for the Subway Excavations.
They are using "24 McKiernan Terry Class "B" Hammer Drills"
They call them "BUSY BEES."
These Drills will put down 8 ft. holes, either *wet or dry.*
They will bore about twice as fast as the reciprocating rock drill.
They use half as much air.
They require no setting up.
There is no time wasted.
They are BUSY all the time.
They are the last word in a shaft sinking tool.
BUY ONE AND TRY IT.

Province of Quebec

Department of Colonization, Mines, and Fisheries.

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, Etc.

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

MINERS' CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10.00 and it is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $10 an acre for SUPERIOR METALS when more than 20 miles distant from a railway and $20 an acre when less than 20 miles.

For INFERIOR METALS the prices are $2.00 and $4.00 an acre respectively.

The attention of prospectors is specially called to the territory in the North-Western part of the province of Quebec, north of the height of land, where important mineralized belts are known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY 228 ST. DENIS STREET, MONTREAL, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The Bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

THE HONORABLE THE MINISTER OF COLONIZATION, MINES, AND FISHERIES, QUEBEC.

Nova Scotia Mines

Gold, Coal, Iron, Copper, Lead, Tin, Manganese, Tungsten, and other minerals.

The Gold District covers more than three thousand square miles. Millions of dollars worth of gold have been taken from the gold fields of Nova Scotia and millions of dollar's worth remain for recovery.

Gold mining in this Province offers good inducement for investment. Labor is cheap and plentiful: timber and fuel are abundant.

Large deposits of iron also are known to exist at various places in the Province; and considerable mining has been done in connection with this mineral, the ore being used locally and shipped to foreign ports.

Among the most important minerals occurring in economic quantities may be mentioned, Coal, Gold, Silver, Manganese, Leadsilver, Copper, Barytes, Mineral Pigments, Gypsum and Tungsten.

Licenses are issued for prospecting for Gold and Silver for a term of twelve months.

The licenses are for areas 150 by 250 feet, and can be obtained for 50c. an area.

Leases can be secured for $2. an area, for a term of forty years; subject to annual rental of 50c. an area.

Licenses to search over five square miles, for a period of eighteen months, for minerals other than gold and silver, cost $30.

Leases for three renewable terms of twenty years each can be obtained for $50., and are subject to a yearly rental of $30.

Royalties are as follows:—

Gold, two per cent on the gross value thereof; Copper, four cents a unit; Lead, two cents a unit; Iron, five cents a ton; Tin and Precious Stones, five per cent; Coal, ten cents on every long ton sold or removed from the mine.

Copies of the mining law can be had gratis, by applying to the Department of Public Works and Mines, Halifax, Nova Scotia, or to Mr. John Howard, Agent General for Nova Scotia, 57a Pall Mall, London, England.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. W. H. HEARST,
Minister of Lands, Forests and Mines,
Toronto, Canada.

THE "ROYAL LINE"

To Europe in

Less than Four Days

LAND TO LAND

The St. Lawrence Route to Europe by the ROYAL LINE shortens the ocean voyage to less than four days, and affords the traveller two days of delightful, sheltered sailing down the great St. Lawrence with its never ending panorama of beautiful scenery and historically famous points. The splendid triple turbine steamers

ROYAL GEORGE and ROYAL EDWARD

hold all speed records and afford the most luxurious accommodation in the Canadian-European service. The English Port, Bristol, is only two hour's run to London by the special boat trains which meet the Royal Line Steamers on arrival.

For further information see nearest Steamship Agent, or the Canadian Northern Steamships Limited.

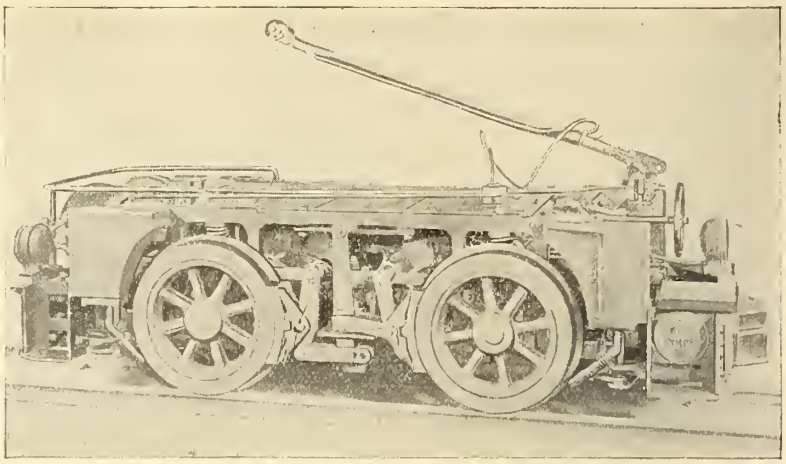
Baldwin-Westinghouse Mine Locomotives

Figure how much animal haulage costs you a month, feeding, shoeing, and the pay of drivers, then let us tell you how much less it costs to maintain Baldwin-Westinghouse Mine Locomotives to do the same work better.



Baldwin-Westinghouse Electric Gathering Locomotive

You never hear of a mine going back to animal haulage after having once used Baldwin-Westinghouse Mine Locomotives. The contrast is too great all along the line; in efficiency, cleanliness and economy of maintenance. We can give you some figures as to the savings effected by electric mine haulage that will appeal to you.

MINING & SCIENTIFIC PRESS

Controlled by T. A. Rickard | **Established 1860** | **H. Foster Bain, Editor** | **Published weekly** | **Thomas T. Read, Associate Editor**

In every issue valuable articles are published on mining, metallurgy, and geology, the latest news from special correspondents at the principal mining centers, letters giving the ideas and experience of successful men, and other items of useful knowledge.

THE MINING MAGAZINE
Established September, 1909
T. A. RICKARD, Editor — **Published monthly at London, England**

A monthly magazine is the natural corollary of a technical weekly. It permits of more deliberate and more extended notice of matters concerning which the news element is less important.

The Mining Magazine includes a review of the world's progress in mining, metallurgy, and economic geology, written by men who have personal knowledge of the regions and conditions discussed.

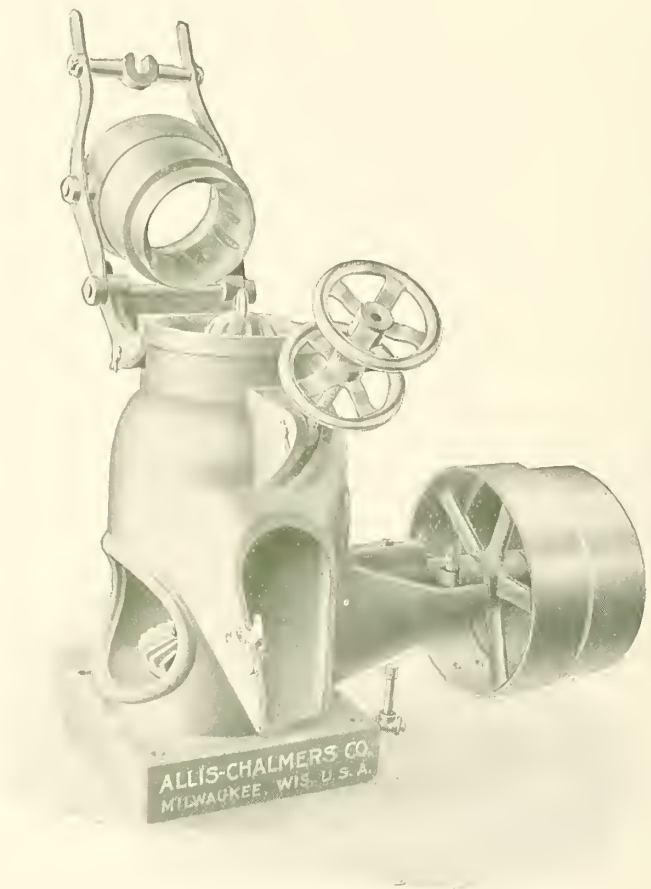
SAMPLING PLANTS

OF ANY CAPACITY



Style "B" Sample Grinder with Hopper Open
(Patented)

To vary the size of the product or to compensate for wear of the grinding surfaces, the practice heretofore has been to make the adjustment by raising or lowering the grinding head. In the Style "B" machine the adjustment is made by raising or lowering the hopper which carries the liner; this is accomplished by means of the hand wheels shown in the illustrations.

The cut shows the Style "B" Sample Grinder with the hopper thrown back. While in this position the hopper is self-supporting and an inspection of the wearing surfaces can thus be easily made.

This machine is fitted with tight and loose pulleys, 16 x 4½ inches, and should run at 250 revolutions per minute.

The machine occupies but little space, is constructed wholly of iron and steel, has the most perfect oiling devices, and is withal unsurpassed by any sample grinder on the market. For further information see leaflet No. 2036.

What Do You Know About Lanco Balata Belting?

The average man who uses belting has very little idea as to what Balata Belting really is. He knows it is a textile belt, but little more. The compound used in making the genuine Balata belt is obtained from a tree in South America. From this tree a gum is obtained similar to that from which rubber is made, and when the gum was first noticed by Europeans, they thought it was rubber. They were surprised to find however, that it would not vulcanize.

This gum was at first deemed worthless, but the very thing that makes this gum no use as rubber makes it very valuable in a belt.

Balata belts will not crack, vulcanize or become hard with age. Any belt user knows the advantage of this.

Not all the Balata belting sold is the pure gum, and in such cases the belting is often inferior. Lanco Balata belting is guaranteed to be filled with pure Balata gum, and the best quality of canvas is used as a base.

LANCO BALATA BELTING.

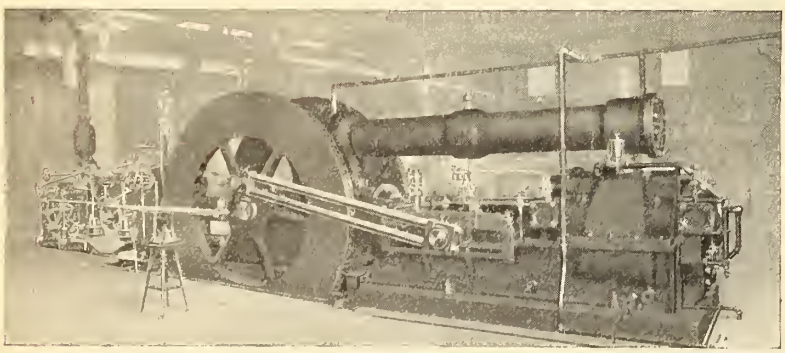
YOU CAN AFFORD CHEAP AIR

ARE YOU GOING TO BUY AN AIR COMPRESSOR? IS THE COST OF YOUR AIR ANY OBJECT?



The price of a cross-compound Corliss machine of the first class may seem beyond your means. But before you select a low priced slide valve compressor, which will COST YOU THREE TIMES AS MUCH AS THE "CORLISS." EVERY DAY FOR COAL, read the rest of this.

You can afford proper fuel economy, and keep your air cost down where it belongs, by selecting a SULLIVAN TANDEM CORLISS TWO STAGE COMPRESSOR. These machines have every advantage that the cross compound has, but the size, weight and price are all less. They cost us less to build, and sell, because they are simpler, have fewer working parts and are carried in stock sizes. They cost you less to install, because they weigh about a third less than the cross compound and require about half the foundation and floor space.

We have convinced many critical engineers; now we are getting their repeat orders. Shall we send bulletin 658 D and figures?

Amatite ROOFING

Mineral Surfaced— Needs No Painting

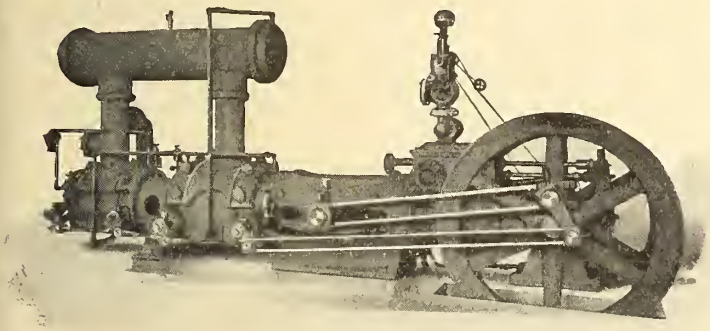
EVERYTHING about Amatite appeals to the man with common sense. He can see its superiority at once—the real mineral surface *which never needs painting;* the two layers of Pitch which is the greatest waterproofing material known; the two layers of heavy Tarred Felt—all these contribute to the popularity of Amatite.

We can make Amatite better and cheaper than anyone else on account of our greater facilities, and consequently we sell it at a surprisingly low figure.

Simply the fact that it needs no painting is enough to make a man sit up and take notice—especially the man who has spent time and money in painting and repainting smooth surfaced roofings.

Write to-day for further information.

The Paterson Mfg. Co., Ltd., Montreal, Toronto Winnipeg, Vancouver, St. John, N.B. Halifax, N. S.



COMPOUND AIR CYLINDERS SHOW

A BIG SAVING

OVER SINGLE STAGE COMPRESSORS

The "RAND" compound straight line compressor offers all the advantages of the original straight line type plus **a big saving in operating costs.**

It is the original straight line machine in a highly perfected state. Embodying the self-contained unit construction; the simplicity of operation and the positive reliability of the original machine, it is just as well adapted to temporary work as to permanent duties.

This steam valve mechanism is second only to the drop release Corliss type.

The air cylinders are of our improved type with unusually large air ports and passages and with extraordinarily large valve areas. Both inlet and outlet valves are what have proved best suited to this class of work, and show exceptionally high efficiencies.

(Many advantages are embodied in these valve designs.)

Equipped with this large efficient intercooler, large valve areas and large cool ports the air-end of this machine is equal to that of the more complicated duplex compressor costing far more to install.

Automatic Regulation.

SWASTIKA Public Notice

Our attention has been drawn to advertisements which have appeared in some of the Toronto papers over the name of CHAS. A. STONEHAM & CO., of 23 Melinda Street, Toronto, also to a circular purporting to be issued by the same parties from their Chicago office at 178 West Jackson Boulevard, also to a circular letter dated 6th November, 1911 and a pamphlet enclosed therein, purporting to emanate from their Chicago office. We feel it to be our duty to the public to state that CHAS. A. STONEHAM & CO. do not in any way represent us and have no authority whatever to make any statements regarding the conduct of our business or the management of our mine. We do not endorse any of their statements and they are not in any way in the confidence of our directorate or mine management and the public are warned accordingly. The company has also caused CHAS. A. STONEHAM & CO. to be notified by its solicitors to desist from any further publications relating to this company's affairs in any and every way. The affairs of this company have always been conducted with an eye single to an honest, clean and capable management and the directors feel that this will be appreciated by the investing public generally.

WIRE GREENING'S ROPE

When sending in your enquiry for quotations on wire rope, satisfaction is assured if you state conditions under which the rope is to be operated. We make a large variety of wire ropes; and we can always ship you a rope that will be of

Satisfactory Quality at a Satisfactory Price

For Swedish charcoal rope we import a high-grade Swedish rod which is drawn and tested in our own mill. For our standard crucible cast steel, best plough steel and acme steel ropes a special wire is made for us by a reliable British firm. We also manufacture rope fittings and a special rope grease for lubricating purposes.

Why the C.P.R. North Toronto Route to Ottawa and Montreal is the Logical One

The train leaves as follows:

Leave North Parkdale - - -	9.15 p.m.	Leave West Toronto - - - -	9.30 p.m.
Arrive North Toronto - - -	9.40 p.m.	Leave North Toronto - - -	10.00 p.m.
Arrive Ottawa, 6.50 a.m.		Arrive Montreal, 7.00 a.m.	
Daily.		Double Electric Berth Lights.	

¶ The residents of Toronto are adjacent to either North Parkdale, West Toronto or North Toronto stations, same being easily accessible and close to residential districts.

¶ The North Toronto route is over an hour faster and overcomes a long hill climb for the train out of Toronto obviating any inconvenience and ensuring early arrival at Montreal and Ottawa.

¶ The roadbed has been improved till it is unexcelled in Canada. Practically half the line is double tracked.

¶ The equipment is "Canadian Pacific Standard," a synonym for the "best" and attentive porters, ensure efficient service.

CHRISTMAS APPEAL
FOR
The Hospital for Sick Children

Dear Mr. Editor,—

Thanks for your kindness in allowing me the privilege of appealing at this Christmas time on behalf of the Hospital for Sick Children, Toronto.

I make this direct appeal to the people of Ontario, for the fathers and mothers of Ontario, outside the City of Toronto, have precisely the same claim for their sick children as regards the privileges of the Hospital, as parents who reside in this city.

In brief the sick children from any place in Ontario whose parents cannot afford to pay, is, on certificate from a municipal officer of any city, town, village or township, treated free.

This is a privilege not granted by any Hospital in the Dominion, or on this Continent.

Let me, in a few words, state that in the last 20 years, since 1891, there have been 4,731 patients from 450 places outside of this city treated free, as the parents were unable to pay for treatment. Last year 384 patients from 234 places outside Toronto were so treated.

The Hospital is not a city but a Provincial institution. The Corporation of Toronto grants $18,000, not only for city children, but towards the maintenance of every patient in the Hospital, and the citizens of Toronto donate an average of $10,000 to the maintenance fund of the Hospital.

It would take more space than you can spare to tell of the good work done for the sick and deformed children of this Province.

Why, in the Orthopedic department in 20 years, nearly 700 children, boys and girls, have been treated for club feet, and about 600 were corrected. Two-thirds of these came from places outside of Toronto, from parents who could not afford to pay.

Surely we have a fair claim for help from the people of this Province.

Every day is Christmas to the child whose little life is saved, or whose crippled limb is straightened with the might of money—your money—and the mercy of the Hospital.

Will you, the reader of this letter, think of what your dollar will do? It helps to restore health and strength, and gives sound limbs and straight feet to crippled boys and girls.

You give wealth to the Hospital, and the Hospital gives health to the children.

Yes, your money can put golden hinges on the door of the Hospital's mercy.

Will you, kind reader, help us and send a spare dollar to Douglas Davidson, the secretary-treasurer of the Hospital, or

J ROSS ROBERTSON,
Chairman of the Trustees. Toronto.

A MERRY CHRISTMAS.

Five years have come and gone since the CANADIAN MINING JOURNAL first greeted its readers. In extending to our Canadian and foreign friends our heartiest wishes for a Merry Christmas, we do so with a full sense of the kind and consistent support that has been given the JOURNAL.

Christmas to all of us is a day of gladness. In the mining camp it should be the best day of the year. It is our sincere hope that the approaching Christmas will be bright and cheery in city, town, and camp.

WORKMEN'S COMPENSATION IN GERMANY.

The Toronto members of the Canadian Mining Institute have, through a committee, framed certain recommendations as to the manner in which employers' liability for the compensation of injured workmen is to be measured and determined. Circumstances do not permit us to discuss these recommendations at present. It may be timely, however, to glance at the way in which the problem is met in Germany. This is all the more appropriate for the reason that we are convinced that some form of compulsory state insurance will prove the only adequate solution of the question in Canada.

German state insurance laws are widely inclusive. Workmen and officials who are in receipt of salaries of $750 per annum, or less, come under the provision. The total number of persons thus insured is about 13,000,000. Compensation for accident amounts to the tremendous sum of $50,000,000 per annum. Nearly $10,000,000 is paid yearly to the families of those killed.

To provide for this outlay the employers are required to organize themselves into associations. The decision of the association can be appealed to an arbitration court.

Until a period of thirteen weeks has elapsed from the date of the accident, no payment is made to the injured person. Support comes meanwhile from a fund to which the employers contribute one-third, and the employee two-thirds. When the accident is traceable to gross carelessness no compensation is paid. It may also be withheld where intentional wrongdoing can be proved.

In the event of death, the family of the victim receives a sum sufficient to cover burial expenses, or a single allowance equivalent to from 20 to 60 per cent. of the annual earnings of the deceased.

It is to be noted that where an injury is so serious as to call for special medical attendance, or to necessitate the services of a trained nurse, the rate of compensation equals the full previous earning capacity of

the injured person. Complete incapacity brings a compensation through life amounting annually to two-thirds of the last year's earnings.

Serious friction occurs in Germany over the question of medical services. Each group, or association, of employers employs its own doctors. These are not always acceptable to the men. In fact, this appears to be a constant source of trouble.

That practically all the expense should fall upon the employers does not seem equitable. The state, the employer, and the workman should share the burden. The interests of all three are inseparably blended. A plan that works injustice to the workman, harms both the state and the employer. In the long run a fair division of responsibility is the only means of achieving peace and harmony.

LEGISLATION ON EXPLOSIVES.

The last two or three years have witnessed a number of shocking accidents in coal mines and in dynamite factories in Canada. Time and time again the Canadian Mining Journal has urged upon the Dominion Government the pressing need of restrictive legislation bearing upon the manufacture, handling, storage, and use of explosives. It was a matter of congratulation that last year the Mines Branch engaged Captain Desborough to look into the whole question of manufacturing dynamite and powder. At the conference held at Ottawa last autumn, Captain Desborough's recommendations were heard by representatives of all the Canadian manufacturing interests and by delegates from many large consumers. Subsequently a bill was drafted under the direction of the Mines Branch. This bill, entitled "An Act to regulate the manufacture, testing, storage, and importation of Explosives," has never become law. For certain reasons it was shelved last session. We had confidently expected that it would be submitted to Parliament this winter. Much to our disappointment we notice in the report of the House of Commons Debates, December 4th, a categorical affirmation by Premier Borden to the effect that the Government has no intention of introducing this session legislation regulating the manufacture, sale, and use of explosives.

It is incredible, of course, that the Dominion Government intends to drop the whole question. Possibly the pressure of business makes it seem necessary to postpone the consideration of the matter. But even this is inexcusable. Legislation is needed at once. At any moment the country may be shocked to learn of scores of lives lost through the improper handling or use of explosives. Such calamities can be prevented. Every civilized country does its utmost to remove the causes of such danger. In the name of humanity, we demand that Captain Desborough's report be acted upon at the earliest possible moment. Criminal negligence may not be too strong a phrase to use in the event of the matter being shelved.

THE MINERAL ALBERTITE.

Forty-seven years ago, Dr. Henry Youle Hind, one time professor of chemistry and geology at the University of Trinity College, Toronto, was requested by the Hon. S. L. Tilley, then Provincial Secretary of New Brunswick, to report upon the geology of that Province. Dr. Hinds' preliminary report was brought out in the year 1865. While it is wide in scope and interesting in almost every page, there are several chapters that, in the light of recent events, are of distinct historic value. To only one of these chapters shall we refer. We hope, later, to touch upon others.

Chapter V. of the report deals exclusively with the origin and geology of the Albert County shales and the mineral albertite. The bituminous shales have received much attention of late years, as also has the albertite. It is in this region also that Dr. J. A. L. Henderson, of London, England, has so successfully exploited the gas and oil measures. Dr. Hind's description of the Albert mine, where the mineral albertite was then being mined extensively, is, in these circumstances, worth noting.

From Dr. Hind's account we learn that, in the year 1849, Dr. Robb, accompanied by Professor Johnston, visited Albert County. Dr. Robb first noticed albertite in October of that year. He describes it as "a mineral pitch or hard bitumen." This is the first recorded discovery. The actual beginning of mining was due, later, to the bursting of a dam on a branch of Frederick's Brook, which exposed a series of massive lustrous veins of albertite. The mineral was christened by Dr. Robb.

Mining operations were in full swing in the year 1852, in which year an extraordinary law suit, Abraham Gesner vs. William Cairns, was commenced. The case hinged upon the character of albertite, the plaintiff contending that it was "true asphaltum"; the defendant holding that it was a coal. A vehement controversy ensued. Embattled scientists smote each other with turgid phrases. The lie direct was given and taken. At last Mr. Justice Wilmot, wearying of the flood of words, instructed the jury to retire. After the jury had deliberated long the decision was reached that the material was coal! Fortunately, this did not, as was at first feared, affect the case. Dr. Hind made several caustic comments upon the flexibility of scientists' convictions.

Let us return ao the Albert mine. Dr. Hind's visit took place in October, 1864. It had then been working for twelve years. An inclined shaft had been sunk to a depth of 1,000 feet, continuously in bituminous shales. The relation of the albertite veins to the adjacent rock, according to Dr. Hind, was not determinable. That they were veins, and not beds, was evident. A great fissure filled with albertite had been worked out to the depth of 750 feet. In the fissure were numerous "horses" of rock. The places from which these "horses" had fallen were filled with al-

bertite. The thickness of the vein ranged 17 feet to nothing. Minute fissures filled with albertite ran in all directions into the walls. From this and other evidence, Dr. Hind rightly concluded that the mineral had been injected into the fissure in a liquid state under great pressure.

After traversing severely the diagnoses of contemporary geologists, Dr. Hind proceeds to show that there were two periods of injection of the material that produced albertite; that albertite is an inspissated or hardened petroleum, and that its source lies in rocks below the Albert shales, rocks probably of Devonian age. His lucid process of reasoning, space will not permit us to trace.

Certain paragraphs in the chapter under consideration discuss tentatively the geology of petroleum. These show that Dr. Hind was much in advance of his day and generation.

No other report of the learned and versatile doctor has more meat in it than this New Brunswick pamphlet. Our patient readers will hear more of it anon.

THE GYPSUM DEPOSITS OF THE MARITIME PROVINCES.

The latest monograph issued by the Dominion Mines Branch is a bulky volume on the gypsum deposits and industries of Nova Scotia and New Brunswick. The author is Mr. W. F. Jennison, who has had long experience in the gypsum-bearing regions of both Provinces.

The status of the gypsum industries in the Maritime Provinces may best be shown by comparing a few statistics. The total quantity of crude gypsum mined annually in the United States is something less than 2,000,000 short tons. Practically all the gypsum imported into the United States, amounting to about 450,000 tons per annum, comes from Nova Scotia and New Brunswick, and is shipped crude. The greater part of it is calcined and manufactured into wall plasters in plants along the New England coast. Relatively small quantities are turned into finished products in the Maritime Provinces.

As the Canadian mineral is of much higher quality than most of the available United States material, the American manufacturer has sought to protect his own market by securing duties of 35 per cent. and $1.75 per ton respectively on manufactured and ground or calcined gypsum; while, as he desires the Canadian crude, only 30 cents per ton is imposed. The Canadian tariff, on the other hand, admits crude gypsum free, places a duty of 8 cents, 11 cents, or 12½ cents per 100 pounds on prepared wall plaster, and 10 per cent., 12½ per cent., or 15 per cent. on gypsum ground but not calcined.

It will be seen that the Maritime Province operators are in a good position to develop the domestic market for manufactured products, and still retain a large export trade in crude. Domestic finished products can be sold at less than $4 per ton at the mill. The American products cannot be profitably disposed of in this country unless at least $6.50 per ton is charged at the mill.

As with all such minerals, the real profit in the gypsum business lies in the grinding, calcining, and further preparation. The average price of crude lump is about $1.10 per ton. The crude ground ranges from $2.50 to $3.10, and the calcined runs up to $8.00 per ton. The cost of quarrying and of handling is very low. Manufacturing costs are extremely moderate. Transportation and marketing are the controlling factors.

There is no sufficient cause for the lack of expansion in this eastern industry. With all the advantages of tide-water shipment, of high grade deposits, of an already established trade in crude and a growing market for finished products, the situation deserves the immediate attention of Canadian investors.

We hope that Mr. Jennison's volume will stimulate interest in the immediate future.

ORGANIZED LABOUR.

The whole truth concerning the horrible series of crimes committed by the McNamaras and their fellow-criminals will probably never be known. Enough, however, has been revealed to show that behind the dynamitards was the carefully disguised influence of persons who were identified with the headquarters of organized labour. This does not mean that the labour organization officially approved the criminal activities of the McNamaras. But it implies certainly that labour organizations in the United States lend themselves to the machinations of the worst kind of nihilists.

This fact has a particularly cogent bearing upon Canada. For instance, the U.M.W.A. spent many thousands of dollars, over one million in all, in attempting to establish its walking-delegates in Nova Scotia. In this attempt, despite the use of most reprehensible methods, it failed.

This is but one instance of the desire of demagogues from the United States to control Canadian labour, to add to their own exchequer the revenues derivable from Canadian miners and other workmen.

We cannot see why Canadian workmen are not capable of managing their own affairs. Much less can we see what Canadian workmen can gain by permitting themselves to be governed by the paid agents of foreign organizations. A broad continental affiliation may be desirable. But actual assimilation must prove disastrous.

Canada has not been cursed with the hired assassin and the professional dynamitard. Why her workmen should contribute to the support of these classes in the United States is not clear.

EDITORIAL NOTES.

The milling costs at Stratton's Independence mill are about $1.25 per ton of ore treated. The average recovery on $3 ore is about 70 per cent., and the capacity of the mill is 4,500 tons monthly.

At Trollhattan, Sweden, an electric smelter has been operating to good effect on zinc-lead ore. The recovery on Broken Hill slime was 64 per cent. of the zinc, 74 per cent. of the lead, and 46 per cent. of the silver.

It is time that the Dominion Government reached some decision as to the status of the Department of Mines. If a capable and responsible minister is not given a separate portfolio we can predict a considerable disturbance.

Deep drilling in Porcupine has aroused much interest. It is announced that at Pearl Lake a depth of 1,200 feet was recently attained, and that ore of commercial value was discovered at that depth. This is good news, although, of course, it requires careful substantiation.

At the suggestion of the Denver Republican, a public Grubstake Fund amounting to $10,000 was collected under the auspices of a committee of the Denver Chamber of Commerce. Thirty-four parties of carefully selected prospectors were sent out to prospect certain localities remote from old camps. Valuable discoveries of gold, silver, lead, and copper were made. It is proposed now to form a Chamber of Commerce Company to develop the claims.

The last meeting of the Toronto Branch of the Canadian Mining Institute was one of the most profitable yet held. While the attendance of Toronto members was not as large as might be, there were several outside members present, including three from British Columbia. The presentation of the report upon Workmen's Compensation was the signal for a long debate. The report was not modified in any respect. It is soon to be submitted to Sir William Meredith.

The cut in the dividend of the Yukon Gold Company's dividend—from 2 per cent. to 1½ per cent.—is explained away by Mr. S. R. Guggenheim, who attributes the reduction to "the extraordinarily dull "season prevailing in different parts of the world," and to the fact that two new steel dredges were not finished in time to be of much use. Glittering generalities don't go far towards soothing disappointed shareholders.

CORRESPONDENCE

THE ORIGIN OF PETROLEUMS.

Editor, The Canadian Mining Journal:

Sir,—Permit me to thank you for your notice in your issue of November 1st, of the paper I contributed a short time ago to the Institution of Mining and Metallurgy on the origin of petroleums, and for your excellent short resume of some of the important points made by me in this paper.

But I would like to be allowed to take exception to the following remark in your article, viz.: "The chief bar to proper discussion, however, is the fundamental divergence in the postulates of each party." This remark most certainly applies to the defenders of the organic theories, who assume so many unsupported positions in this discussion; but I claim that it cannot justly be said that I postulate or assume when I back my position and arguments with so much evidence.

My opponents, the "organics," assume, for instance:

That hydrocarbon compounds (such as petroleums) must necessarily have an organic source, because they are carbon or organic chemical compounds. This is evidently an assumption, a postulate, founded merely on a play on words.

They also assume that the petroleums found in the "sands," evidently come from bituminous shales—that is to say, that the petroleums found in a certain kind of reservoir, "the sands," come from the bitumen found in another kind of reservoir, the shales. This position is asserted without evidence, and is a reasoning in a circle which can prove absolutely nothing as to the origin of the petroleums, or bitumen, in either the sands or the shales.

They also assume that the petroleums are the product of distillation of "coals," or other organic remains, in the sedimentary strata; although the oil bearing strata are always found to be in the unaltered and undistilled state.

They also assume that the above distillation of organic remains can proceed at low temperatures—although all known processes of distillation are always the result of high temperatures.

They also assume that time—long time—can take, and has taken, the place of temperature in the distillation of certain of the organic remains entombed in the strata, and has thus slowly distilled them into petroleums. Why are not the coal beds and the unaltered sediments all distilled then? All of them have had ample time.

They also assume that, because some of the sediments are rich in fossils, these beds are bound, or were bound, to be highly bituminous—although, as every paleontologist knows, it is the rarest thing in the world to find bitumen or petroleums of any kind in a fossil. It is not found in one out of a million cases; and the geologist knows that the oil sands (some of which are enormously productive in petroleums), are not fossiliferous. In the above postulate, they take the assumed position that the soft tissues of animals are preserved and entombed with their shells or bones during the formation of strata, when we can observe every day in the actual processes of entombment in nature, that the very reverse is the case.

They also assume that petroleums can originate in fine-grained sediments, such as shales, and travel through the pores of these sediments for miles, laterally to accumulate under a distant anticline, when, if that was possible, it is quite evident that these petroleum products would, instead, travel up to the surface only a few hundred feet, or one-half or three-quarters of a mile away, at most, and escape. This postulate of possible migration and accumulation of petroleums through and from the mass of the surrounding sediments, is assumed against ample evidence furnished in every oil-field, that the sedimentary strata surrounding the oil-fields or pools, are absolutely impervious, since they keep the petroleum hemmed in their porous reservoirs, under very strong gas pressures always recorded in every field. If these surrounding sediments are impervious enough to prevent the gas from escaping, they cannot be the source from which this gas comes in. I have shown in my papers, that the "organics" use a number of other postulates without any more evidence in support than they can adduce for the assumptions mentioned above. It remains to be shown by them, that I have done likewise, and that I have proceeded also by "postulates." Let them take up one by one the facts and arguments which I have repeatedly advanced, and show that they are also assumptions—not founded on real evidence. I have been waiting for many years, to have some one do that, and would like to have him come forward at last. If not, I shall be forced to conclude that neither you, Mr. Editor, nor any one else, can prove that I have "postulated" or assumed in my presentations and discussions of this most important subject.

Yours, etc.,

EUGENE COSTE.

Ottawa, December 4th, 1911.

The Editor, CANADIAN MINING JOURNAL:

Sir,—Permit me to call your attention to an erroneous statement made by Mr. A. Gordon French, reported under the heading "Urges Bounty on Zinc," p. 779 in your December issue. The erroneous statement is as follows: "While in Ottawa, said Mr. French, he had been told that both Dr. Haanel and Dr. Ingalls had abandoned the problem," referring to the investigation of processes for the treatment of the complex zinc ores of British Columbia. Such is not the case. In fact, the investigation and experimentation are being pushed with earnestness and vigour.

In order to make more rapid progress in our enquiry, we have added to the staff by availing ourselves of the services of Mr. Dedolph, who has assisted Mr. Snyder in his electric smelting experiments at Nelson, B.C., and who is a metallurgist, well known in British Columbia.

Yours sincerely,

EUGENE HAANEL,
Director of Mines, Ottawa.

CONCENTRATION AT HUDSON BAY MINES.

Editor, CANADIAN MINING JOURNAL:

Sir,—I read with much interest the article by Mr. H. G. Young, in your issue of November 15th. Mr. Young describes very clearly the methods employed at his mine. There are one or two points, however, on which I would like to interrogate him.

In the first place, why use a 16-mesh screen, when there is no after-grinding of the ore?

In the second place, why use stamps at all, if the ore is amenable to treatment at such a coarse mesh?

Of course, Mr. Young's answer may be easy enough. I shall appreciate a full one.

Yours, etc.

Madoc, Ont. G. H. GILLESPIE.

BOOK REVIEWS.

THE TECHNICAL ANALYSIS OF BRASS AND THE NON-FERROUS ALLOYS — By WILLIAM BENHAM PRICE AND RICHARD K. MEADE — 267 PAGES — PRICE, $2 — PUBLISHED BY JOHN WILEY & SONS, NEW YORK, AND THE RENOUF PUBLISHING COMPANY, LTD., MONTREAL.

It has been estimated that on the rolling stock of American railways alone there is over $21,000,000 invested in bearing metal. This sufficiently accurate approximation gives one some idea of the importance of right technical control of the manufacture and use of alloys.

The book whose title appears above purports to cover the whole field of the chemical analysis of brass and the non-ferrous alloys.

In chapter I., engineering alloys are dealt with generally. Chapter II. takes up apparatus for electro-chemical analysis. After these introductory chapters, there come fifteen successive chapters, describing the methods of determining each metal used.

The last 110 pages are occupied with careful outlines of applied examples of alloy analysis.

The general plan of the book is well conceived. The arrangement is logical, clear, and convenient. Possibly enough general facts about alloys are not included. But, on the whole, the book is by far the best presentation of the subject that we have seen.

GEOLOGY OF THE LAKE SUPERIOR REGION — "Monograph 52 of the United States Geological Survey, entitled 'The geology of the Lake Superior Region,' by C. R. VAN HISE and C. K. LEITH, is now ready for distribution. This monograph represents the first attempt of the Geological Survey to cover the geology of the entire region in a single volume. It contains 641 quarto pages and includes chapters on all the iron and copper producing districts and full descriptions of the iron and copper ores. It is accompanied by accurate maps of all the producing districts and a general geologic map of the region. The illustrations number 49 plates and 76 text figures, comprising maps, sections, diagrams, and half-tone reproductions of photographs of ores and minerals. The price is $2.50, the cost of publication. Remittance should be made by postal or express money order to the Director, United States Geological Survey, or in cash—the exact amount."

In this concise and unappreciative way the director of the United States Geological Survey announces the publication in revised and condensed form of a vast amount of painstaking study of the iron and copper deposits of Lake Superior. The geological map covers approximately 181,000 square miles, of which about three per cent. are of commercial importance as ore-bearing areas. The region includes the native copper mines of Keweenaw Point, the most important of their kind in the world. There are also included the Marquette, Menominee, Gogebic, Mesabi, and Vermilion iron ranges, not to mention several smaller ones, which make the region the most important iron ore centre in the world.

All of these regions are described in detail, with excellent coloured geological maps and numerous illustrations. A full chapter is given to "the pre-Animikie iron districts of Ontario," wherein the geology and iron ore occurrences of the Lake of the Woods, Steep Rock Lake, Atikokan, Mattawin, and Michipicoten districts are described. Another chapter describes the geology and ores of the Gunflint Lake and Loon Lake areas of the Animikie, and makes comparisons with the Mesabi.

In a chapter on the Keweenawan series the geology of Lake Nipigon, of Nipigon and Black Bays, of Michipicoten Island, and of the east shore of Superior is discussed.

Chapter XVII., of 110 pages, on iron ores, is a most important exposition of ore deposits. Conditions of sedimentation and methods of secondary concentration are discussed. There is also a description of the iron formations, methods of exploration, ore reserves, methods of mining and transporting. The statement is made that 7,200,000 feet of diamond drilling has been done on the American iron ranges in the search for ore, at a cost of at least $21,600,000.

Another chapter discusses in an equally thorough manner the origin of the copper ores. A short chapter deals with the silver ores, confined almost wholly to Ontario. Chapters are included on the general geology, on the physical geography, on the history of mining, on the plaistocene geology, and one giving a full bibliography.

To all students of the pre-Cambrian areas of Canada, and to engineers and others interested in the exploitation of iron or native copper ores, the volume is invaluable.

PERSONAL AND GENERAL

Mr. Frank Loring, with two assistants, is examining the St. Anthony mine, Sturgeon Lake, Ontario.

Mr. W. M. Brewer has retired from the management of the Matanuska Gold Mines, Ltd., with mining property in Alaska.

Mr. H. P. Davis has returned to New York. He will presently visit Cobalt, Swastika and Porcupine to gather material for his annual review.

Mr. A. D. Miles, who represents the Canadian Copper Company, has taken an office in the new Standard Bank Building, King Street west, Toronto.

Mr. George F. Loudon has retired from the directorate of the Scottish Ontario Gold Mining Syndicate, Limited. Colonel William Clark, of Glasgow, has been appointed in Mr. Loudon's place.

Mr. J. M. Ruffner, manager of the North Columbia Gold Mining Company, operating hydraulic placer-gold mines in Atlin camp, British Columbia, has gone to his home in Cincinnati, U.S.A., for the Winter.

Mr. John Hopp, who owns four or five placer-gold mines in the Barkerville section of Cariboo district, British Columbia, and whose hydraulicking operations are on the largest scale of any in the district, is spending the winter on the coast.

Mr. D. L. H. Forbes, mining and metallurgical engineer, has opened an office at 306 Manning Chambers, 72 Queen Street west, Toronto. In addition to his private practice, Mr. Forbes will undertake metallurgical testing and designing on behalf of the Merrill Metallurgical Company of San Francisco.

Mr. Anthony J. McMillan, liquidator of the Le Roi Mining Company, Ltd., has gone to London, after having spent several weeks in British Columbia and the adjoining State of Washington, in connection with the disposal of the company's mining and smelting properties.

Mr. J. W. D. Moodie, of Salt Lake City, Utah, U.S.A., has been appointed general manager of the Britannia Mining and Smelting Company, Ltd., in the place of Mr. Robert H. Leach, resigned. Mr. Moodie has been general manager of the Tintic Mining and Development Company and the Yampa Smelting Company, both operating in Utah.

Messrs. W. E. Carter and Alexander H. Smith, both well-known Toronto mining engineers, have formed a partnership, under the name of Carter and Smith. The temporary Toronto address is "care of CANADIAN MINING JOURNAL, Toronto. The firm's northern address is South Porcupine. Both Mr. Carter and Mr. Smith have a thorough knowledge of Canadian mines and ore deposits.

Mr. O. B. Smith, jr., superintendent of mines of the Granby Consolidated M., S. & P. Co., Ltd., lately returned south, after having spent some time at the company's Hidden Creek copper mine, Observatory Inlet. Mr. George W. Wooster, treasurer and director of the company, and Mr. Wakely A .Williams, superintendent of the company's large smelting works, are both back at Grand Forks, B.C., from visiting the Hidden Creek property.

Mr. W. H. Trewartha-James has resigned the position of general manager of the Tyee Copper Company, Ltd., with mines and smelting works on Vancouver Island, British Columbia. He left Victoria for England about the middle of November. Mr. W. J. Watson, manager of the company's smeltery, has been appointed acting general manager. Messrs. T. H. Wilson (chairman), Harry von Berg, and J. Hancke, directors of the company, all of London, have lately been visiting the company's offices and properties.

Mr. Robert H. Leach has resigned as general manager of the Britannia Mining and Smelting Company, after having during several years successfully directed development work at the company's mines on Britannia Mountain, Howe Sound, British Columbia, and the varied experimental work done in the works at Britan-

nia Beach in connection with the milling and concentration of copper ores. He will spend the winter in Southern California, whence he has gone for a few months' rest and recreation.

Mr. R. G. Drinnan, formerly general superintendent of the Crow's Nest Pass Coal Company, was in Toronto during the first week of December. He was one of several British Columbian members who attended the meeting of the Canadian Mining Institute (Toronto branch), meeting at the Engineers' Club on Saturday, December 2nd. He has returned to Vancouver for the winter.

Mr. Colin Campbell, of Campbell and Deyell, attended the last meeting of the Toronto branch of the C. M. I., and spoke briefly upon the formation of the Porcupine branch, the organization meeting of which will be held in South Porcupine on December 16.

Upon his return to British Columbia from Pittsburg, Pennsylvania, whence he went with Mr. R. F. Tolmie, Deputy Minister of Mines for British Columbia, Mr. Robert Strachan, district inspector of mines, Hosmer, Crow's Nest Pass, made a full and comprehensive report on the proceedings he witnessed at the United States National Mine Safety Demonstration, and as an outcome of which he has made recommendations to the Provincial Minister of Mines, with a view to the further improvement of several matters connected with the coal mining industry in his (Mr. Strachan's) inspection district.

The Gypsum Deposits of Nova Scotia

By W. F. JENNISON, M.E.*

Description of Deposits.

The deposits present much variety of colour and texture. The greater part in texture may be classed as compact or crypto-crystalline, with lesser quantities of granular or saccharoidal. In some places considerable quantities of selenite occur, showing folia, sometimes a foot or more across and transparent throughout, as shown in Plate III.; and the fibrous varieties are seen in many places associated with the gypsum and marls, Plate IV. Crystals of selenite are often found disseminated irregularly through the gypsum beds. A characteristic example of this is shown in Plate V., usually in groups or bunches, sometimes in veins of importance.

Anhydrite often occurs in extremely variable proportions in many of the deposits, with great irregularity, and the occurrence of this mineral, which is practically valueless, with the gypsum, often interferes with the economic operation of the quarries.

The following brief description of the gypsum deposits of Nova Scotia, with analyses furnished by Mr. F. G. Wait, chemist for the Mines Branch of the Department of Mines, is intended to give essentially the conditions of most economic importance, rather than to deal at length with the geological conditions of each deposit, which are very similar.

Sheet No. 2, Aspy Bay, Victoria County.

Extending from the Atlantic Ocean, inland about six miles, in a somewhat triangular shape, occurs one of the most important gypsiferous areas on the island of Cape Breton. Its occurrence, comprising nearly 8 square miles. is in comparatively low lands surrounded by hills of the older Pre-Cambrian rocks, often 1,000 feet in height, and it is practically all underlain with gypsum.

Two rivers, the North Aspy River and the Middle River, run through this area, exposing cliffs having a height from 40 to 70 feet, and their meadows make a very easy gradient from the deposit to the sea.

The exposures are extensive. The rock is white, and mottled white and grey, compact crystallization showing some little anhydrite, which carries petroleum in small (pea size) cells at the base of exposure.

At present the deposits are inaccessible for want of a harbour. The natural outport would be North Pond, at Dingwall. This pond, which has sufficient depth of water for shipping purposes, has been separated from the ocean by the washing of sand and gravel up from the ocean bed, forming a narrow bar across the entrance, and thus closing to navigators one of the best harbours on the coast.

Sheet No. 4, Cheticamp, Inverness County.

On this sheet will be seen a gypsiferous belt, skirting the metamorphic hills from the mouth of the Cheticamp River on the north to well below Friar Point on the south, a distance of over 13 miles, and at no place a greater distance than 2 miles from the sea coast. Its width varies from about 600 feet to over 2,500 feet.

The principal outcrops occur on the southeast side of Aucoin or Mill Brook, about 3 miles from the northern extremity, and at Grand Etang harbour, about the same distance from the southern extremity.

Between these two points, and their extensions both north and south, the gypsum is mostly concealed, but is traceable by the characteristic sink holes and hummocky ground, under an overburden of clay.

The northern exposures, shown in Plate VIII., on the east side of Aucoin Brook, are composed of a series of precipitous cliffs, from 60 to 180 feet high, above the level of the brook, and forming a narrow plateau parallel to and at no great distance from the base of the great plateau of northern Cape Breton.

The southern exposure occurs near the head of Grand Etang harbour, where the high cliffs of white compact gypsum outcrop near the water's edge.

The northern exposures have been developed by the Great Northern Mining Company, who have established a plaster mill near the face of the cliff. This area alone contains very extensive deposits of gypsum, made up of different beds interstratified with limestone. The first or lower bed, overlying the metamorphic series, consists of a compact variety of snow-white and white gypsum; resting on this is a bed of

*Abstracted from monograph, "Report on the Gypsum Deposits of the Maritime Provinces," issued by the Mines Branch, Ottawa.

carboniferous limestone having an average thickness of about 100 feet; above the limestone is a very extensive bed of grey and white selenitie gypsum. The valley of the Mill Brook is all underlain with gypsum, and eovered with from a few inches to a few feet of red clay; on the western side the gypsum again erops out with considerable prominenee.

The high bluff of selenitie grey and white gypsum is often cut by vertieal veins of pure transparent selenite, running parallel to the strike, with veinlets or stringers cutting off horizontally. One of these veins has a width from 8 to 20 feet, and may be traeed for at least half a mile.

Sheet No. 11, Mabou, Inverness County.

In this seetion there are numerous gypsiferous areas which are more or less available for eommereial purposes. They eomprise a total area of 6.55 square miles.

At Finlay point, on the sea eoast, and about one mile north of Mabou eoal mines, oeeur cliffs of exeellent white eompaet gypsum from 35 to 50 feet in height. This area extends along and borders the sea coast for nearly 3½ miles. The exposures here are large, and every indieation points to an extensive deposit of gypsum of a quality suitable for all ordinary manufaeturing purposes, but the sea eoast is rugged, and very little proteetion eould be given to shipping. To operate this deposit it would, therefore, be necessary to make the shipping point at Mabou harbour, a distanee of 3½ miles over a rather diffieult pass.

At Mabou harbour the most important deposits are located, and known as the Col. Snow property, and the Beaton property.

The roek is exposed in eliffs from 45 to 60 feet high, and consists almost wholly of a white eompaet gypsum, with smaller quantities showing microseopie erystals of selenite. Small quantities of anhydrite may be seen at the base of the cliffs.

Following east to Hillsborough, and south to Southwest Mabou, large gypsiferous areas oeeur, but eonsist in the greater part of eoneealed measures. Large outerops of a very soft, grey, and dark grey, granular gypsum, suitable only for land plaster, oeeur at Hillsborough. At Southwest Mabou the roek is similar in texture, and has assoeiated with it fine erystals of selenite.

Sheet No. 12, Smith Island, Inverness County.

On this sheet oeeur three small gypsiferous areas eonsisting of 212.8 aeres. The largest and most important of these is that of 148.8 aeres, on Smith Island.

This island is situated about one mile from the mainland, and opposite Port Hood. Its topography is low, and the exposures, whieh in the greater part are on the exposed side of this island, appear as extensive beds assoeiated with shales and earbonate of lime, and may be traeed from shore to shore by broken land and pits or sink holes.

The gypsum oeeurs in alternating layers with the earbonate of lime and marls, the latter earrying extensive quantities of fibrous gypsum.

At Ragged Point, and at Cape Susan, at one time, was an area of eonsiderable importanee, whieh has been, by erosion of the sea, divided into two, having a total area of 64 aeres. The oeeurrenee here, like Smith Island, has few outerops, and the gypsum and limestone are elosely assoeiated. Large quantities of marl are also prominent.

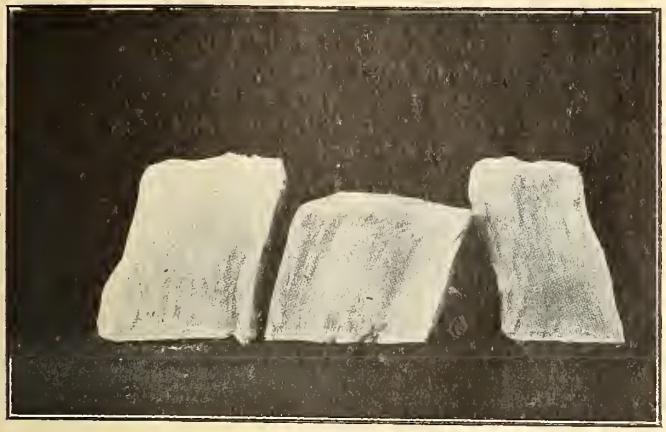
Transparent crystal of Selenite.

The close proximity of these areas to the railway and eoal fields makes them desirable for manufacturing purposes.

Sheet No. 15, Malagawatchkt, Inverness County.

On the south side of Denys basin is a narrow gypsiferous area skirting the shores of the Bras d'Or lakes from McKenzie Brook on the northwest, to about half a mile southwest of Matheson's wharf, and eontinuing southwest by numerous small islands and peninsulas to West Bay. In this area of 6.44 square miles, including that portion of sheet No. 16 southwest of Denys basin, numerous outcrops of gypsum are seen as at Plaster Island, and on the River Denys road, George Island, Green Island, and Floda Island.

Many of these outcrops are of little importanee, being low and having but small quantities above sea-level. Several, however, have sufficient prominenee to be considered as available supplies. The exposure on Donald McKinnon's farm, River Denys road, has a



Fibrous Selenite Crystals.

height averaging 50 feet, with a length of 275 feet. This deposit, and its extension 2½ miles northwest to Plaster Island, shows probably the most important deposit in the whole area. At Plaster Island the exposure is from 10 to 40 feet in height on the shore, and covers an area of 4 to 5 acres.

In texture and colour, this rock is a soft white compact variety, having some anhydrite associated with it.

Sheet No. 16, Washabuck Peninsula, Victoria County.

This area includes the deposits at McKinnon harbour, Ottawa Brook, Washabuck River, Nineveh, Little Narrows, Maciver point, Deadman point, McKay point, Boulaceet harbour, Lieutenant pond, Iona, Jamesville, Red point, and south side Whycocomagh Bay. The total area is 25.54 square miles. Here all varieties of texture and colour may be found. The exposures are many and large. Anhydrite occurs frequently, outcropping in large irregular masses. This is especially true at Nineveh, and at Washabuck, the former showing a perpendicular face of 60 to 80 feet and a length of over 800 feet. At the latter place it shows on a road leading from Washabuck River to Little Narrows, for nearly a mile in width.

At Ottawa Brook, the Newark Lime and Cement Company, of Newark, New Jersey, U.S.A., started operations in 1908. They have opened up several deposits, and built a railway connecting them with their shipping pier, constructed on the north side of Great Bras d'Or Lake.

The rock at some of the points opened up, although a soft white compact variety, shows much disturbance, being badly fractured and folded; due to local pressures—probably the conversion of anhydrite into gypsum. At another point, only a few hundred feet distant, a dark carbonate of lime is seen graduating into gypsum. The lower left corner shows the lime, with streaks of snow-white gypsum. The right and upper side is a soft white compact variety of gypsum, showing very little disturbance.

At Little Narrows (south side), on the properties of M. J. McAskill and widow McAskill, very large exposures are seen. At the latter the face is about 100 feet high and over 600 feet long; the rock is an excellent quality of soft white compact variety with but few irregularities. It is situated on St. Patrick channel, about one mile from the shipping point, to which a practically level route could be secured.

Composition is shown by the following analyses:

	Per cent.	Per cent.
Lime	33.30	33.67
Sulphuric anhydride	46.00	46.00
Water, loss on ignition	21.16	20.70
Insoluble mineral matter ...	0.24	0.20
	100.70	100.57

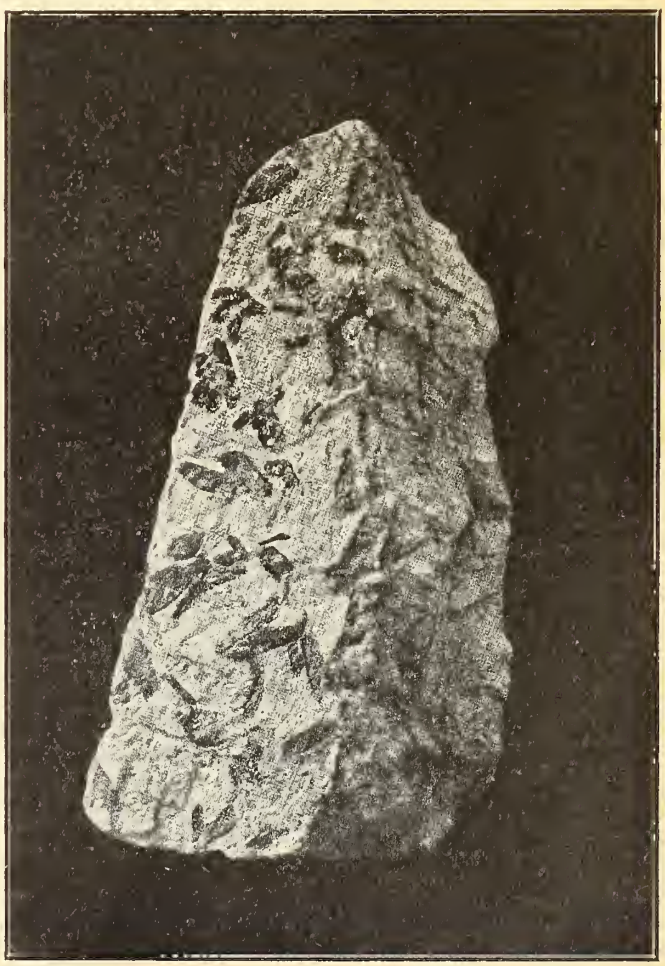
Sheet No. 18, Port Bevis or Big Harbour, Victoria County.

From Baddeck Bay on the west to St. Ann Bay on the east may be considered as one continuous gypsiferous bed, having an area of 15.83 square miles.

It contains many important outcrops of both gypsum and anhydrite. On the shores of the Great Bras d'Or Lake, west of Port Bevis, extensive cliffs of anhydrite occur. Another cliff, 70 feet high and 650 feet long, is shown in Plate X. The prominence of this mineral is greater on or near the shores of the lake, and again at the contact of these measures with the older rocks, and may be a conversion from gypsum by metamorphic action.

The farther it is possible to get from these points the freer the deposit seems to be from anhydrite. Thus, it is seen that the best exposures of gypsum are found at the head of Baddeck Bay, about 1 mile from deep water shipping, where very little disturbance is apparent. These exposures occur in a valley where there are extensive outcrops of soft, white, compact gypsum, without any appearance of anhydrite.

At Port Bevis a few years ago the Victoria Gypsum Company carried on extensive operations, but



Gypsum with embedded selenite crystals.

owing to inereasing oeeurrenee of anhydrite at depth, this plaee was abandoned. This is also true of a point west of Plaster mines, where a small quarry was operated many years ago (1875) by Mr. Duncan MacDonald, of Montreal, who exported annually about 5,000 tons. It has been notieed that both of these quarries are in the region of most disturbance.

Sheet No. 20, St. Ann, Victoria County.

In this seetion, at Goose eove and at Oregon, 4½ miles from the mouth of North River, occur small gypsiferous areas. At Oregon there are 134 acres; at Goose eove two areas, having a total of 230 acres. At the former plaee the measures are all eoncealed; at the latter large exposures from 40 to 60 feet in height are seen. One of these has been opened up and operated for several years by the Vietoria Gypsum Company. It is situated 3½ miles by rail from their shipping pier at Munroe point. The roek in eolour is white, light grey, and mottled white, the white having prominenee. The outerops indicate a soft eompact variety, and operations prove this to be true to a depth of 30 to 40 feet; but during the summer of 1908, while sinking on the floor of the quarry, anhydrite was discovered in eonsiderable quantities.

Sheet No. 23, Tom River, Richmond County.

On the southeast side of Great Bras d'Or Lake is a gypsiferous area of 2.7 squarc miles, eomprising Campbell eove, Hay cove, and MeNab Creek, in whieh oeeur several outerops of gypsum. Some of these outerops eonsist of a very excellent, snow-white, eompact variety, resembling alabaster; while others, espeeially at Tom River, show an exeess of lime. It is free from all evidenee of anhydrite, and is easily aeeessible to water shipment.

The following analyses show the average quality of the roek:—

	I. Per eent.	II. Per eent.
Lime	32.95	34.04
Sulphurie anhydride	46.64	44.28
Water, loss on ignition	20.93	21.07
Insoluble mineral matter	0.13	0.67
	100.65	100.06

Sheet No. 25, Madame Island, Richmond County.

This sheet eomprises not only the deposits of Madame Island, but of Port Riehmond, on the north side of Lennox passage, and a very small deposit near Pirate harbour in Guysborough County, making a total gypsiferous area of 6.57 square miles.

The most important of these deposits is that on the north side of Madame Island, and the south side of Lennox passage, where there is a large gypsiferous area of 3.77 square miles. The outerops of gypsum in this area having most prominenee are situated about 1½ miles west of Lennox Ferry landing, and about 1 mile from the shore. At this point the exposures eover many aeres in area, and have a height of from 30 to 70 feet. Here, years ago, H. C. Higginson, of Newburgh, New York, operated a quarry, and exported large quantities of the erude material to the United States. The gypsum is a white eompaet variety; but it has, irregularly assoeiated with it, mueh anhydrite. The oeeurrenee of this mineral, no doubt, had much to do with the elosing of the quarry, although there still remain large quantities of good gypsum. This, together with exeellent natural shipping faeilities, and the inereasing demand for the produet, should be an impetus to reopen and operate this extensive area.

Cliffs of anhydrite, Great Bras d'Or lake, C.B.

Analysis:—

	Per cent.
Lime	33.33
Sulphuric anhydride	45.32
Water, loss on ignition	20.92
Insoluble mineral matter	0.22
	99.79

Sheet No. 26, Askilton, Inverness and Richmond Counties.

In this seetion we have what may be known as the Hastings area, of 75 acres, at Port Hastings; the Beaver Dam Lake area of 1.6 square miles on the border line of Inverness and Riehmond eounties, and about 4½ miles east of Point Tupper; the Askilton area of 1.8 square miles, at Askilton, 3½ miles from the Intereeolonial Railway, or about 6 miles east of Port Hastings. Also a small area about 1½ miles south of Askilton, of 302 acres, on Inhabitants River.

The Inhabitants River area, and the Beaver Dam Lake area, have very little importanee, being situated

in low ground. The Beaver Dam Lake is only traceable by the pits or kettle holes, and hummocky ground. In the banks of Inhabitants River small outcrops are seen, but both areas seem to be covered heavily with clay.

The Askilton area is the most important in this section from all points of view. It has large outcrops, some as high as 70 feet above drainage level, and the greater part is an excellent white compact variety, with smaller quantities of granular.

The Strait of Canso, the natural outport for the deposit—being an open port all the year—makes this deposit desirable, especially to those who export large quantities of crude rock, as it is the nearest deposit to a winter port in the province.

The following analyses from samples of the different deposits will serve to show the average composition of this rock:—

	I. Per cent.	II. Per cent.
Lime	40.48	33.80
Sulphuric anhydride	55.48	46.08
Water, loss on ignition	3.90	19.86
Insoluble mineral matter ..	0.44	.....
	100.30	99.74

No. I. and II. Average samples, Hastings area.

Sheet No. 40, Shubenacadie River, Colchester and Hants Counties.

At the mouth of the Shubenacadie River, on the east side, occurs a black Carboniferous limestone, known as black rock, carrying small veins of manganite. Succeeding this is a series of soft marls and sandstones, filled with veins of reddish fibrous gypsum running in all directions, and it is not until Pitch Brook is reached that we meet solid gypsum exposed in prominence. Here, about 1 mile from the shore, occur massive beds, which extend almost continuously eastward to Beaver Brook, and to Irvin Lake. At Pitch Brook the gypsum is light grey in colour, and has a compact texture. Many years ago the deposits were operated, and the product exported to the United States. At Beaver Brook the rock is a compact white variety, with some alabaster showing in some of the exposures; however, anhydrite has prominence. Ascending the river on the western side there is a small area known as Stephens area, where a good white compact variety of gypsum is seen, associated with soft reddish blue marls. Here is the largest deposit of fibrous gypsum known in the provinces, occurring in veins running through the marls in all directions, often 12 inches and 18 inches wide, and when cleaned from the associated marls is very pure. In 1869, these deposits were operated for the fibrous variety, and a mill was erected at Noel, 15 miles from the deposit, at a cost of $12,000, for manufacturing the product into terra alba. These works were destroyed by fire the following year, and all operations abandoned.

The Cove Quarry at Cheverie.

Proceeding up the river, on the west side, the next deposit of importance is that of Capt. John Graham, just above and opposite Eaglesnest point. This, formerly known as Big Rock, presented a snowy white front to the river, and for many years was operated for export purposes.

It is a massive bed arranged in layers and bent in conical shape; the base and interior showing anhydrite, and the whole resting on a base of Carboniferous limestone. It is here the Windsor series of the lower Carboniferous crosses the boundary line (Shubenacadie River) into Colchester county, and at this point it has a width of less than 1 mile, and west, about 1½ miles, it tapers to a mere connecting link, but soon widens again on the Fivemile and Kennetcook Rivers. Proceeding on the western side of the river, 1 mile south of the Fivemile River, again the gypsiferous area is met with in prominent outcrops of gypsum,

which are almost continuous for several miles. At Rose point, Urbania, and Admiral rock, massive white beds are exposed on the river bank, from 40 to 60 feet in height; and not only at the river bank, but from one to three miles west prominent exposures occur of excellent quality.

Crossing the river near Fort Ellis point, and descending again on the eastern side, large exposures are seen; but not in such prominence as those on the opposite side of the river. At Green Oak, on the property of Thos. Phillips, large and prominent exposures of white, snow-white, and blue gypsum occur, in compact crystallization. This property is near the river, where shipping facilities are good, and in the past was operated quite extensively. Again, on the property of G. W. Dart, and Tupper Fisher, outcrops occur, but here an excess of carbonate of lime is shown. The gypsiferous area included in the above description is 14.14 square miles in extent.

It will be seen by the above that in this section there is practically an unlimited supply of gypsum of good quality; and at one time considerable business was done exporting the crude material, but many causes have militated against the successful operation of these deposits. Operations were carried on in the days of small sailing vessels owned by those who were familiar with the tides of the Shubenacadie River, but as the size of vessels increased, and before the steamboat was known on this river, the plaster trade became controlled by a few, and these deposits were the first to suffer. To those interested in this trade it may be worthy of note to mention that the tide at the mouth of the Shubenacadie rises 30 feet in three hours and recedes in the same length of time. At Eaglesnest point the bore at high tide is often 10 feet high.

The following analyses will serve to show the different qualities of rock in this section:—

From Beaver Brook—	I. Per cent.	II. Per cent.
Lime	36.80	33.20
Ferric oxide and alumina	0.40	.....
Sulphuric anhydride	51.44	46.40
Water, loss on ignition	11.73	20.79
Insoluble mineral matter	.....	.....
	99.87	100.39

No. I. The interior of a boulder of anhydrite which has been exposed for about 25 years.

No. II. An outside coating about 1-inch thick taken from No. 1.

GYPSUM DISTRICT "E."

Sheet No. 41, South Maitland, Hants County.

The eastward continuation of the Kennetcook River valley is the valley of the Fivemile River, both rivers having their origin in close proximity, the Kennetcook flowing westwardly to the Avon, the Fivemile River eastwardly to the Shubenacadie. The Dominion Atlantic Railway (Midland division) follows these valleys for nearly 30 miles west of the Shubenacadie River, which makes the gypsum deposits in this section very accessible.

On this sheet there are three gypsiferous areas, comprising a total of 9 square miles.

The most important of these is that at Latties Brook, which is a continuation of the Windsor series eastward. It is here that the Windsor Plaster Company has a quarry and gets a partial supply for its calcining mill at Windsor. The quarry is situated near Burtons station, on the south side of the railway, and has an exposed face 40 feet high, covered with from 10 to 15 feet of clay. Attempts have been made, with a considerable degree of success, to remove this clay by the hydraulic method.

The rock is a white compact variety, well suited for the manufacture of plaster of Paris. This bed may be followed westward for some miles, but there are only a few outcrops, the greater part being concealed under a heavy overburden of clay. North, about 1 mile, near the public highway, prominent outcrops are again seen, but the rock is not as good in colour or texture as at Burtons.

Going east from Burtons we meet precipitous cliffs, from 75 to 140 feet in height, and over 2,000 feet long, on the Lawrence property, at Andrew Hayes (known as The Cave), and on the Royles property. On the Geary property, about 150 feet north of the railway and having a strike about parallel with it, is another exposure, with a length of 1,400 feet, and an average height of 85 feet.

On the Hayes property, the upper parts of the cliff show considerable disturbance, and are badly folded and contorted; while near the base the beds are more even in structure. The rock on this face shows considerable anhydrite, but on the south or opposite side of the ridge, where the rock has more covering, it is a good white gypsum, with some greyish white and blue associated. The face continues westwardly, with practically the same height, to the Lawrence property, and has a stratification more horizontal and even. In other conditions it is similar to the Hayes property.

On the Geary property, the rock again shows disturbance, with considerable anhydrite, and veins of dark carbonaceous and reddish gypsum of inferior quality cutting through it.

The natural shipping port for the deposits of this area would be the Shubenacadie River (distant from 3 to 5 miles), but it would necessitate the construction of a shipping pier above the railway bridge. Unfortunately, not sufficient attention was given to draw efficiency in the construction of this bridge, and the provision then made for this purpose is not suitable for modern shipping; and, therefore, makes what would be otherwise desirable gypsum properties (not only the above described, but several others on or near the Shubenacadie River), practically inaccessible for export purposes.

The next area of importance is that at Glencoe, which was mentioned in the description of sheet No. 40. It is to the south, and some distance from the valley of Fivemile River and on very much higher ground. The shipping port for this is on the Shubenacadie River, about 2 miles above the mouth of the Fivemile River.

Going north on this sheet to Selma, near the head of Cobequid Bay, there occurs a small isolated gypsiferous area of 1.7 square miles. The topography of this is generally low dike lands, and the outcrops, which have but little prominence, occur about 2 miles from the shore. The rock is a grey slaty structure, with small quantities of white granular.

(To be Continued.)

Notes on Workmen's Compensation Act

(Written for the Canadian Mining Journal by
R. G. Drinnan.*)

[Editor's Note.—At the request of the Journal, Mr. Drinnan has outlined his views upon the Workmen's Compensation, as applied to mining. Mr. Drinnan's long experience in the coal mines of Western Canada lends specific value to his opinion. Since the Toronto branch of the Canadian Mining Institute is taking up the same subject, this contribution is more than ordinarily timely.]

It is generally conceded that workmen engaged in hazardous occupations should be recompensed for loss sustained by injury. Further, that the means of awarding this compensation be such that it can be obtained promptly or without recourse to the law courts. The Workman's Compensation Act comes nearest to fulfilling these conditions; but there are some objectionable features in it which might be modified in any new Act.

In the first place, the burden the Act imposes must be borne entirely by the employer. Naturally, he protects himself by placing his "risk" with an insurance company. The insurance company (a soulless corporation) is therefore responsible for the payment of claims. It is the business of the insurance company to make it as difficult as possible for a workman to obtain compensation. It is done in this way:—

The Act presupposes that in cases of dispute as to liability the parties will agree on an arbitrator. Seldom do they agree, and it is often necessary to ask the chief justice of the province to appoint one. It lies with the workman claiming compensation to ask for this appointment by the court and that necessitates the services of a solicitor. Law costs then begin to accumulate and although the award may be in his favour the workman never receives the full amount awarded. It is often less than half this amount when the sum claimed is small. The object of this is to make a workman accept as payment of his claims an amount smaller than the Act allows him as a compromise against having to take arbitration proceedings. Clearly this is one of the things the Act was intended to circumvent.

Another way of settling claims under the Act is to appoint a committee, an equal number from each side, with power to appoint an arbitrator if they fail to agree. In practice this works out better for the workman, as he always gets paid the full amount of the award. The weakness of this arrangement lies in the fact that the workmen's representatives on the committee are elected by popular vote and generally they feel that to retain popularity they must succeed in obtaining some compensation for every claim presented.

The better plan I believe would be to have an arbitrator appointed by the Government and paid by it. He does not necessarily need to have a legal training. Ordinary common sense and some practical knowledge of conditions of work in the various industries involved are the requisite qualifications.

In the second place, accidents are more numerous since the passing of the Act. This may be accounted for to some extent by the fact that minor accidents are now reported; but the more serious accidents have not decreased. This is not the fault of the employer because the Act is an incentive to him to take every precaution and exercise all due care for the safety of his workmen—where the appeal to humanity failed the added liability has largely succeeded. The fault lies to a large extent with the workmen themselves. They know the Act protects them financially in case of injury, and this adds to the temptation when working on contract to increase their earnings by taking greater risks. Even a workman who has nothing to gain by taking risks is liable to become more careless when this knowledge is present.

To remedy this, to put a check to foolhardiness on the part of the workmen, something different from the saving clause of "serious neglect and wilful misconduct" will have to be adopted. To prove serious neglect you must show that the workman neglected to do something he knew he should have done. To prove wilful misconduct you must show he did something he was told he should not do. The Act places the onus of proof on the employer, and it rarely happens that he can establish any such proof. A broader meaning should be given to this term, not to deprive the workman of compensation, but to check needless risk and carelessness.

In the third place, the Act should make it compulsory for workmen to report all injuries, no matter how trifling, sustained by them in the course of their employment, before absenting themselves from work, so that it can be investigated on behalf of the employer. Compensation has been paid for loss sustained by injury when there has been considerable doubt as to where and when the injury actually occurred.

In the fourth place, the Act should be more explicit in the matter of a medical referee in cases of temporary incapacity. Workmen will malinger and abuse themselves to the extent of delaying recovery from injury while they are being paid compensation. Some means of checking this should be devised.

While the doctors who are attending the injured workman are paid by the workmen and appointed by them, it will be impossible to get them to handle this matter impartially. When a workman sustains injuries necessitating the payment of compensation he should at once be placed under the care of an independent doctor and when discharged by him payment of compensation should cease. Any failure to comply with instructions from this doctor should be cause for non-payment of compensation.

The medical referee should be a permanent appointment therefore and not one called in only in cases of dispute after the workman is supposed to have recovered.

---

*Mining Engineer, Vancouver, B.C.

The Bluebell Mine, Kootenay Lake, B.C.

At the last general meeting of the Western Branch of the Canadian Mining Institute, held at New Denver, British Columbia, on September 13, Mr. S. S. Fowler, general manager for the New Canadian Metal Company, Limited, owning the Bluebell mine, situated on the east shore of Kootenay Lake, B.C., read an interesting and instructive paper, entitled "Costs and Conditions at Bluebell Mine, B.C." The costs submitted were those over a period from July 1, 1909, to March 31, 1910, inclusive. They cover the cost of extracting from the mine 43,067 tons of ore, plus 100 feet of drift deadwork, and of concentration of that quantity of ore, together with general expenses. The detailed statements of costs will not be available for publication until after they shall have been printed in the Quarterly Bulletin of the Canadian Mining Institute, but the following excerpt from the paper may be given:

The Bluebell mine is situated in a peninsula which projects from the east side of Kootenay Lake, B.C., and its orebodies, outcropping at 100 feet or less above the water-level, are attacked through an adit whose portal is within 100 yards of a wharf at which all supplies are received and from which all product is shipped. Adjacent to the portal are located the concentration plant and shops; and the office, laboratory, and living quarters, save certain cottages, are within 200 yards thereof, while the greatest distance from which the ore so far developed has to be hauled does not exceed 300 yards. It will be seen, therefore, that accessibility is practically perfect.

The living quarters comprise (a) several 4-roomed cottages, all plastered and painted, situated not more than 500 yards from any part of the work, provided with light and water, and each surrounded by a fenced plot of ground about 60 by 120 feet. These are rented at $12 per month each, to employees with families. (b) A bunkhouse containing 27 bedrooms and two recreation rooms. All these are plastered and painted and open on to covered verandahs, there being no internal passages. No more than three men occupy any one room. (c) A dry-house adjoins the bunkhouse and contains in one room six shower baths with cement floors and ample sinks, laundry tubs, and hot and cold water. In a connecting room are lockers for each employee, properly ventilated and provided with steampipe below. Toilets are in a small, separate, but conveniently placed building, and are fitted with flush closets on a cement floor. All buildings are steam-heated when necessary. (d) Within 50 yards of the bunkhouse is the boarding house, with seating capacity for 100 men. In the basement of this building is a post office, and a small store supplied with the common necessities of the employees; but no employee is either compelled or influenced in any way to trade there.

The dining room is ceiled and painted white and amply lighted on north and south sides, thus being made a cheerful place, the influence of which on the dispositions of those who use it, to say nothing of their appetites is notably favourable.

An easily accessible field, situated some 300 yards from the living quarters, is much used for sports, such as baseball and football. Several of the men have maintained their own canoes or small motor boats in the near-by bays.

Without reference to the natural and quite exceptional beauty of the location, such are the physical conditions surrounding the lives of those who work at Bluebell. It need hardly be said that they attracted the best class of men, who, when once they secured a position, were, with few exceptions, wise enough so to conduct their work and behaviour as to keep it.

On the part of the management, there has been no attempt at paternalism. It prohibits nothing but canvassers, gamblers, and too much intoxicating drink. It does nothing and provides nothing which can be regarded as charity. The result has been that while it is probable that all hands know that low costs are essential to a continuance of operation, we gathered together a staff and force that possesses what I may call a collective conscience, the working of which has contributed in large degree, no doubt, to the low costs in this country of high wages and expensive materials.

Wages. Practically all work was done by day labour rather than by contract, and the wages paid and regarded as "standard" for the district, were as follows:

For eight hours:		
Foremen	$5.00 to	$6.00
Shift-bosses	4.00 to	4.50
Machine miners and helpers		3.50
Hand miners		3.25
Millmen	3.00 to	4.00
Smiths and helpers	3.50 to	4.00
Compressormen		4.00
Muckers, etc.		3.00
Carpenters and machinists ..per hour		50
Nine hours—		
Outside labourers		3.00

The approximate average wages for all classes was $0.433 per hour.

Cost of Ore-Extraction.—All development charges were placed to debit of "capital" or previously written off, so the following statement includes nothing for the cost under the head of development.

As stated before, the ore was attacked through an adit-level and all stoping was done from above it; consequently no charge for hoisting, pumping, or other vince are on the surface. Mesabi transportation costs expense incidental to working from shifts appears.

The orebodies are found in the upper part of a stratum of crystalline limestone of undetermined thickness, striking north and dipping west at about 35 deg. The deposits, of which only two have been worked, while they have a sharply defined and strong roof, are irregular in plan and section and are to be classed as large in size, the workings as a whole taking the form of chambers as much as 100 feet wide, in a north-south direction, and, say, from 10 to 50 feet or more in height. This means large and free-working faces. Wherever necessary or advisable, pillars of ore have been left from time to time, for the support of roof; but subsequently some of them have been removed without difficulty or danger. In this manner, timbering for support has been successfully avoided and, practically, the only wood in the mine is in chute-timbers and track-ties. While several raises through limestone underlying ore have been put up to serve as ore-passes, the irregularity of parts of the deposits

has neeessitated much shovelling and wheeling, thus off-setting to a considerable extent the main advantages of large working faces and no timbering. As a rule, the ore may be said to "drill" and "break" well, although most of the low-grade material is so full of quartz erystals as to cause excessive wear on the steel.

Power is derived from a water supply under a static head of more than 700 feet, and compressed air is used on two 3¼-inch piston drills and one hammer drill. Generally, one of the former was in use during three shifts per day, one for two shifts, and the hammer drill, ordinarily, only one shift. These machines, with three or four hand miners in narrow work, kept the output of the mine up to the requirements of the mill, about 160 tons per day. I regret to say that I have no adequate record of the drill shifts nor the lineal feet of hole drilled.

Haulage is done in trains of five 16-foot cars drawn by a horse, except as to a few occasional cars run out by hand at night. The cars were commonly loaded by the muckers, who also assisted the driver in making up trains by various loading-chutes.

The normal underground crew consisted of:

Foremen and shift-bosses	2
Timberman	1
Driver	1
Miners	14
Muckers, etc.	15
Total	33

Here followed the detailed tables of costs and some comment on the nature of the ore.

Summary—

	Per ton.
Ore extraction	$0.984
Concentration and shipping	0.498
General	0.376
Total	$1.858

In conclusion, let me say that whilst the result just given is to be regarded as very satisfaetory under the conditions set forth, it must be remembered that the figures indieate neither a profit nor a loss. They do not consider the necessity of continuance of development of the mine, the provision of funds for further construction if found desirable, nor are they concerned at all with those items of expense the determination of which is a function of the directors — partieularly amortization and interest, which are very important factors in the final test of the value of a mine.

Hollinger Reserve Mines of Porcupine

(Written for The Canadian Mining Journal.)

About three miles in a direct line south-west from the village of Timmins, in the township of Tisdale, is the Hollinger Reserve mine in Ogden. The company owns fourteen claims in the various Porcupine townships, totalling 560 aeres. Apart from the necessary annual assessment work, all efforts of the management are being concentrated on the six claims in Ogden, which form a rectangular block of land lying on the banks of Mountjoy Creek. This little river has a width of about fifty feet, furnishes all necessary water

Mountjoy River, running through Hollinger Reserve Properties.

power, and when a few jams of timber have been removed, will be navigable all the way to the Metagami River.

The Ogden properties of the Hollinger Reserve are in a direct line with the Hollinger mineralized belt, and are connected with the better known camps of Porcupine by a good wagon-road cut through the forests and corduroyed aeross the swamps. They are covered with a forest of large pine and spruce, that will furnish a sufficient supply of timber for building and mining purposes; while the eleetric transmission line from Wawaitin Falls, on the Metagami River, will run directly across the property, so that power may be readily and eheaply obtained.

For the most part, this seetion of Porcupine is fairly level; but three of the elaims on the Hollinger Reserve are marked by a rocky eminence that is "pillow-like" in form. It is on this exposure that most of the prospecting has been done, and it is here that the gold discoveries have been made. On the adjoining low-lying eountry, the rock is hidden by an over-burden of stratified gravel and sand, and further work will be neeessary to see whether it also contains similar gold-bearing veins. But the veins now uncovered extend in all directions, and visible gold has been found at intervals along the strike.

The Hollinger Reserve, it may be recalled, was originally acquired by Bennie Hollinger, the discoverer of the famous Hollinger mine, and one of the prospectors that cut through the Porcupine bush. Such engineers as Messrs. J. B. Tyrrell and J. G. Harris, men who have studied carefully the geology of the district, and who are thoroughly familiar with the mineralization of Northern Ontario, agree that it offers substantial possibilities.

The mineral eonditions of these properties would indicate that all of these rocks are of the Keewatin age and the existence of the heavily mineralized rock below has doubtless been caused by the presence of harder and more resistant rocks, so that it seems not improbable that other layers, or areas, of schist may be found throughout the sand and gravel covering on the balanee of the property.

The veins already uncovered on this roeky eminenee, have been earefully sampled, and as soon as the main shaft will have reaehed a reasonable depth, it will be possible to determine their downward extension.

In addition, the eompany plans an extensive diamond-drilling eampaign, and has already arranged for several drill holes in the lowland, to determine the western extension of the veins that seem to crop up in a direet line with the Hollinger mineralized zone.

Cook and Sleep Camps of the Hollinger Reserve Mine.

Probably the most pieturesque, and surely the most healthy location in the Poreupine mining distriet, is that of the Hollinger Reserve mine, so far as the health and happiness of its mine management and erew are eoneerned. The company has a complete set of eamps and mine buildings, consisting of cook-eamps, bunk-houses, offices, storehouses, assay office and stables, which are fully equipped and sufficiently large. The mine buildings and bunk-houses follow the bank of the ereek, and with the enlarged development work that is being planned, will soon beeome quite a little village.

During the past summer, an extensive campaign of surfaee prospeeting has been earried on, and during the winter most of the work will be underground. The eompany is in possession of suffieient information, how-

Showing Veins Nos. 3, 4 and 5, on the Hollinger Reserve Mines.

ever, to direct intelligently the underground work. It is hoped that before April, the work done will have proven up a body of ore that will justify more extended operations. To this end a six-drill eompressor is to be installed. Eleetrie power has already been arranged for.

Ogden township is finding considerable favour with mining men just now, on aecount of the many strikes made during the late summer.

In addition to its holdings in Ogden, the Hollinger Reserve Mines Company owns properties in both Tisdale and Deloro, on whieh, with the exception of the assessment work, nothing will be done until spring. On both of these groups of elaims, there are several apparently large veins exposed, but sufficient stripping has not been done to sample intelligently the property. One most eneouraging feature may be noted regarding the holdings along Mountjoy Creek. Surface

Ben Hollinger on the left, and No. 2 Vein Hollinger Reserve.

indieations.—There are five main veins, avering from 2 to 6 ft. in width, and from 250 to 350 ft. in length. These veins oeeur in a band of sehist, whieh is in eontaet with the greenstone to the north, and the porphyry-diorite to the south. The sehist is 125 ft. in width, separating the two formations. There are numerous other smaller veins, which show visible gold. Visible gold can be seen at intervals along the five main veins for the entire distanee uneovered, and the opinion of the engineers who have examined the property combined to give the impression that the veins as shown on top of the ground will merge in one large ore body both vertieally and laterally, and that eonsequently eonsiderably greater enrichment will be found with depth.

CORRESPONDENCE

High-grade Ore Deposits of the Portland Canal District.

The Editor Canadian Mining Journal—

Sir,—In the Journal of November 15 you publish under the above heading a eontribution from "An Occasional Correspondent." Now, the purpose of this communication is not to take any exception to the obvious advertising of the Rush-Bagg group of elaims seeured in that contribution, but to ask you to permit me to state my regret that you have seen fit to allow anonymous refleetions on the fairness of the Provincial Mineralogist for British Columbia. Surely it is not too much to ask that when serious refleetions are made in print upon Government officials, the name of the person making them shall also be published, so that his standing be made evident to the public, and from his eonnection with mineral claims, or whatever else be affected, opportunity be at the same time given to judge whether or not he is a disinterested and impartial critic.

If you will open your copy of the Annual Report of the Minister of Mines for British Columbia for 1910 you will find at the bottom of page K 66 the three lines your correspondent first quoted; then turn over three pages, and you will find the second three lines quoted. No explanation was given that between the two sentences quoted as text, there are about 1,800 words of context. Further, the second three lines quoted are a specific reference to a portion of the Portland Canal mining camp that has since been proved to be exactly what the Provincial Mineralogist expressed the opinion it would be, namely, "comparatively low-grade concentrating propositions." In fact, milling and concentrating experience has since proved that the average value recovered has been even less than that mentioned by the Provincial Mineralogist in his report. The fitness of such a manifestly unfair critic to pass opinion on the fairness or otherwise of others is, in my judgment, very doubtful.

It is not my intention to here call in question the existence of high-grade ore deposits in the part of Portland Canal mining camp your anonymous correspondent appears to be deeply interested in. I may, however, direct attention to a few points bearing upon the subject. Your correspondent, immediately after alleging that the statement of the Provincial Mineralogist "is manifestly unfair and wholly unwarranted," states that his purpose is "to remind the investing public that the ores of Portland Canal are not all low grade; that the initial expense of operating high-grade properties is negligible in comparison with the cost of necessary equipment for exploiting low-grade ore; and it is by no means proven which class of properties in this district will develop the best dividend-payers."

Just so; it is not proved that high-grade ore occurs in quantities. A little later he tells of "rawhide ores," and says the minimum assay value of such ore under present transportation facilities would be in the neighbourhood of $50 per ton," though what "present" or any other "transportation facilities" have to do with assay value is beyond my ken. Later, he tells that Rush and Bagg's camp is at an altitude of 2,000 ft. and is reached by horse trail 3½ miles from the Portland Canal mill (from which, I have been informed, there has long been a good wagon road to Stewart, and now there is a railway). Under such conditions it would seem that a few energetic claim owners could have this year, if not last, managed to ship some of the $50 per ton ore, if they have any quantity worth shipping. It is not the men who rely upon high assay returns from, perhaps, picked specimens, who make a prosperous camp, nor those who wait for someone to come along to buy undeveloped claims, but the men who will get out ore, under even much greater difficulties than your Rush-Bagg correspondent outlines, and if it lack such energetic claim-owners the "high-grade" portion of the Portland Canal camp may be expected to continue to be non-productive.

In conclusion, I would remind your correspondent, first, that the opinions expressed in his official report by the Provincial Mineralogist have thus far been found, if anything, too favourable, and, next, that after "these high-grade deposits," of which he (the correspondent) writes, shall have been developed and made productive on a commercial basis, to use his own closing words, "it will be early enough to pass judgment upon their value."

E. JACOBS.

Victoria, B.C., December 1, 1911.

Coal on Vancouver Island, B.C.

(By E. Jacobs, Victoria, B.C.)

A consular report relative to coal on Vancouver Island, British Columbia, sent to Washington, D.C., and quoted from by mining journals and newspapers, being inaccurate in one or two details, the following excerpt from a paper on "The Undeveloped Coal Resources of Canada," submitted by Mr. D. B. Dowling, of the Geological Survey of Canada, to the Annual Meeting of the Canadian Mining Institute held in the City of Quebec last March, will show accurately the situation, as presented by Mr. Dowling, who is one of the leading coal geologists of the Dominion and probably the most fully informed concerning the coal resources of Western Canada. In passing, it may be stated that the table containing an estimate of the area of known coal-bearing lands of British Columbia and their probable coal-content, which Mr. Dowling included in his paper above mentioned, was reprinted in the "Report of the Minister of Mines, British Columbia," for 1910 (p. K 176). This table shows an estimated aggregate area of 1,351 square miles, containing 40,221,000,000 tons of coal, in the following proportions: Anthracite, 61,000,000 tons; bituminous, 39,674,000,000 tons; lignite, 490,000,000 tons. It is not unlikely a revision of the figures, taking into account the results of explorations made during the year 1911, would now give a larger area and estimated coal-content to fields situated in the Skeena country, and, perhaps, also to parts lying north of Cariboo, but no extensive changes are known to have taken place that would similarly affect Vancouver Island coal-fields. Concerning the latter, Mr. Dowling wrote:

"KOSKEEMO AREA AT HEAD OF QUATSINO SOUND.

"The area occupied by rocks of lower Cretaceous age covers 10 square miles. Borings in certain localities have demonstrated that over sections of the area a 3-ft. seam is mineable. The coal is bituminous of good grade. Area, 5 square miles, with 3-ft. coal, equals 9,000,000 tons.

"SUQUASH AREA.

"This was, perhaps, the first of the Vancouver Island coal areas to be mined. The Hudson's Bay Company operated a mine near Port McNeill for a few years prior to 1851. The coal seams are thin, none found being, perhaps, more than two feet in thickness. The area occupied by Cretaceous rocks is large—14 miles along the coast and about three miles wide (not including the extension beneath the sound)—42 square miles. As the richness of the area is not proven the estimate is made for:—Area, 10 square miles; thickness of coal, 3 ft.; equals 19,000,000 tons.

"COMOX AREA.

"The northward extension of this area has not been determined. Of the part known, Mr. Richardson enumerates the following coal seams:—

"Brown's River, 7-ft. seam.

"Union Mine, 10 ft. and 4 ft. 4 in. coal.

"Trent River, 3 ft. and 3 ft. 8 in. coal.

"Baynes Sound Mine, 6 ft. and 5 ft. 10 in. coal.

"Minimum area, exclusive of that at northern end or under Baynes Sound, 300 square miles, having an estimated thickness of coal averaging 6 ft., equals 1,152,000,000 tons.

"NANAIMO AREA.

"In the Nanaimo area two seams of workable thickness are mined. The upper is called the Douglas and the lower the Newcastle seam.

"The Douglas seam, near Nanaimo, is about 8 ft. in thickness, but increases to the west to a maximum thickness of about 14 ft.

"The Newcastle seam varies from 17 ft. west of Nanaimo, to 10 ft. at the Wellington collieries, but may be said to average about 5 ft. over the major portion of the field. The basin extends south to Haro Straits, and, including the submarine portion between the islands, represents an area of about 350 square miles. Borings on Saturna Island demonstrate the presence of the coal at the southern extremity of the basin.

"Estimate of content, allowing 6 ft. each for the two seams, would give a total of 1,344,000,000 of coal.

"COWICHAN AREA.

"This is a smaller basin, of about 50 square miles, lying south-west of and adjacent to the Nanaimo coalfield. The area appears to contain beds of greater age than those bearing coal in the Nanaimo field. Small portions, where the upper measures occur, may prove productive, but for this area a small estimate only is warranted—9 square miles, 4 ft. of coal, equals 23,000,000 tons."

The consular report now under notice is quoted as having stated that "Last year the Nanaimo field produced 1,615,160 tons of coal." This would appear to be an erroneous statement. The following figures have been taken from the "Annual Report of the Minister of Mines" for 1910:

	Tons, 2,240 lbs.	
Western Fuel Company—		
No. 1 Shaft and Protection Island.	364,689	
Northfield (Brechin)	148,181	
		512,870
Canadian Collieries (Dunsmuir), Ltd.—		
Comox (Cumberland)	518,426	
Extension	380,482	
		898,908
Pacific Coast Coal Mines, Ltd.—		
Fiddick (South Wellington)	171,971	
Suquash	2,839	
		174,810
Vancouver-Nanaimo Coal Mining Co., Ltd.—		
(New East Wellington)		29,442
Total production (Vancouver Island)...		1,616,030

Of this gross production 1,094,765 long tons were produced from mines in what Mr. Dowling regards as being the Nanaimo district—including the Western Fuel Company's several mines, Extension Colliery, Fiddick Colliery, and New East Wellington Colliery. Of the remaining 521,265 tons, Comox mines produced 518,426 tons, and Suquash 2,839 tons.

It may be stated, in conclusion, that both the Western Fuel Company and the Canadian Collieries (Dunsmuir), Limited, are opening new coal mines and making large expenditures in additional plant, machinery, and other facilities for production of coal in considerably increased quantity, while the Pacific Coast Coal Mines, Ltd., is also providing for an enlarged output, though in smaller degree than the older companies.

The Economy of Power

By L. P. Hammond.*

In lode or quartz mining, and in placer mining on a large scale, the cost of power is a most important factor in the cost of operation, and the difference between the cost of operation and the selling price of the product of the mine is the only basis upon which the real success if the mining venture can be measured. Mining is a business governed by the same rules that apply to any other business, and the success of an undertaking in mining is not by any means entirely determined by the assay value of the ore found. There are four accepted ways of obtaining power for mining in our mountains.

First, steam power plants. Until recently most of our mines were operated with steam power plants, using, in a majority of cases, coal for fuel. The cost of this coal varied all the way from $3.00 a ton in mining districts like Leadville, where coal can, in many cases, be delivered directly from railroad cars into the mine's coal bin, up to $15.00, and even $18.00 a ton, where the coal has to be hauled or packed long distances from the railroad. It would be hard to place any average cost figure on wood burned for fuel, but it is safe to say that considering two cords of wood the equivalent of one ton of coal for steam-making purposes, in very few places have operators been successful in obtaining wood at a lower cost than the equivalent of $5.00 per ton for coal.

The second method is the use of a gasoline engine. In general, this method of obtaining power has been limited to out of the way, remote districts and the use of power for prospecting purposes, and consequently on a very limited scale.

The third method is the use of water power. This has been decidedly limited, partly because of the relatively high first cost of developing and equipping such a power, and partly because few of our mountain streams prove a reliable source of power during the winter months.

The fourth and last method is in the purchase of custom electric power. Colorado is now particularly fortunate in the extent to which the distribution circuits of custom electric power companies cover its mining districts.

*From the Colorado School of Mines Quarterly.

In considering the reduction in mining costs effected by this extensive power service the elements of the cost of power must be considered. These are an annual fixed charge, involving a reasonable percentage to cover:

First. A fair return to the investors upon the money wrapped up in the equipment.

Second. Another percentage charge by which the original cost of the equipment is spread over a number of years of the probable useful life of the equipment, in other words, writing off the cost of the original equipment by distributing it over a number of years operation.

Third. Percentage charges to cover insurance and taxes upon the equipment. The sum of these charges constitutes an annual fixed charge, which endures and must be counted as part of the cost of operation whether or not the equipment is used.

Next comes the cost of labour, since except in very small power plants it is, of course, necessary to provide men for the care and operation of the equipment. It should be borne in mind that so long as the plant is operating at all, this labour cost is also a fixed cost, that is, it does not fluctuate with the amount of energy actually generated by the plant.

Then comes the cost of fuel—coal, wood, gasoline—as the case may be. This will vary in some proportion to the amount of power actually generated, but not in direct proportion thereto, because the machinery of a large power plant is much less efficient at a small load than at a load approximating the capacity of the plant. In other words, it is necessary to put more fuel per unit of energy produced into a large plant working on a small load than into one working at the capacity of the plant. In addition to the cost of coal delivered at the coal mine, plus the cost of freight, plus the cost of handling from the railroad to the bins, there is another factor calculable in dollars and cents, and this factor is the extent of supervision that must be given by the mine manager to secure an adequate and reliable source of supply. Under the climatic conditions that prevail in our mountains, especially during the winter, one can readily see why in mining operations this is in itself a very considerable factor.

Next comes the cost of repairs on the power plant equipment, and last of all the cost of oil, waste, and miscellaneous supplies. It will be seen that the cost of power consists of a fixed cost, irrespective of the percentage of its capacity at which a plant is worked, and a variable cost which fluctuates to a considerable extent with the amount of work done by the plant.

Where custom power can be obtained the user thereof is certain of a continuous supply of power; he does not have to worry about snow-bound or washed-out railroads, about the quality of the fuel used, nor about obtaining and keeping skilled engineers. He does not have to see that men are at the mine an hour or two before the miners go to work in order to be certain that steam is up and custom power can not go to town to spend a holiday and fail to report for duty on the following morning.

When it comes to the first cost of equipment of the property a very great saving is invariably effected. Of course, conditions vary widely, but it is safe to say that the first cost of electrically equipped mining machinery or the installation of electric motors to drive a mill will range from 33⅓ per cent. to not more than 66 2-3 per cent. (with 50 per cent. as a fair average) of the cost of putting in steam-operated machinery with the necessary boilers. The steam end of the machinery with the boilers will cost, installed, not less than $100.00 per horse-power; while the installation of electric motors to accomplish the same work will cost not more than $40 per horse-power, and of course, a horse-power is the same in energy whether produced by an electric motor or by steam or gasoline engine. Here is a saving on a moderate sized equipment of $60.00 per horse-power. If we allow the very moderate overhead charges of 15 per cent. per annum, we already have a saving in our operation of $9.00 per horse-power per year, on the fixed charges alone before any energy whatever has been used.

The rates of the different power companies vary considerably as does the method of rate making, but it is safe to say that in almost every instance the cost of custom electric power is considerably below the cost of the necessary coal and labour to produce the same amount of energy by steam.

Another important element is that without custom electric power few of the moderate sized and small mines would use electricity because of the high first cost of the small, isolated electric plant. The facility with which electric power can be distributed to different pieces of machinery with relatively small loss of energy in such transmission is of particular importance where power is used to operate so many different machines at so many different points as in the mining industry. For instance, consider the use of the small mine pump operated by steam from boilers at the surface. To carry the steam down the shaft to the pump a great deal of the energy of the steam is lost by radiation and condensation, and such a pump will require fully three times as much steam per horse-power generated in its engines as would be required by a first-class engine located on the surface near the boiler. On the other hand, electricity can be carried down the shaft to the bottom at very high efficiency.

The manager of the Wilson Mining Company, at Robinson, Summit County, reported that during the heavy water periods it cost from $1,200 to $1,500 a month for coal for the operation of the pumps, and this with coal at about $5.00 per ton. The pumps were converted to electric operation with a resulting cost of less than $250.00 per month for power. At a large mine in Leadville, the operators of which do not care to be quoted as to their unit costs, hoisting from 600 feet depth with a steam hoist cost six and a fraction cents per ton. This company is now served with an electric hoist at the company's standard rate and the mine is now hoisting from 700 feet depth at a cost of about 2¾ cents per ton.

The Central Colorado Power Company is the first company in the state to publish its rates for service and to adhere thereto rigidly. Its standard rate is a combination rate, consisting partly of a flat rate per horse-power used and partly of a meter or energy rate, based on the actual consumption of power. In the custom power business the purchaser of power likes to purchase his power strictly on a kilowatt hour basis, paying for just what energy he actually consumes. On the other hand, the custom power company likes to sell all its energy strictly on a flat basis, that is, at a given charge per horse-power of maximum demand per month, irrespective of the extent to which the service is used. Neither basis is fair alike to the power company and to the consumer, and the reason for this can be made very plain by a brief example. Supposing you yourself were in the custom power business possessing a plant with a capacity of 1,000 horse-

power. In this event you would probably have an investment of something like $75,000 on which you would have to earn in addition to your coal, labour, repairs and supplies cost, a fixed charge of 15 per cent. per annum, in order to cover your entire cost. Suppose a man came to you and wanted to contract for power on a meter basis, and having arrived on a price per horse-power, you then proceeded to sell him 1,000 horse-power. Now, if he used this power only two hours a day, he would tie up the entire capacity of your plant, and at the same time would use only 1/12 of the energy you could generate with this investment, and in so doing he would use 2,000 horse-power hours per day. On the other hand, suppose another man came to you for power and used only 100 horse-power of your capacity, but operated 20 hours a day. He would also use 2,000 horse-power hours a day, exactly the same amount of energy as would be used by the first man, but the second man takes only 1/10 of your plant capacity. Obviously, you could not afford to sell each of these two men power at the same rate per horse-power hour. Likewise, the man who wanted 1,000 horse-power for only two hours a day could not afford to pay you the same price per horse-power month as could the man who wanted service for 20 hours per day. Consequently, the trend of all modern rate-making in custom power service is towards a compromise between these two conditions. The Wisconsin Public Utility Commission has done most excellent work in arriving at fair methods of negotiation between custom power plants and their consumers, and this commission has invariably ordered the custom power companies to base their charges partly on a flat rate on the maximum demand for power by any one customer and partly on the energy that a customer actually used. Under such a method of rate-making the cost of power to a consumer depends on what is called "load factor." The "load factor" is the percentage representing the relationship of the average load throughout a given period to the maximum load at any one time in that period.

I am not in possession of all the rates quoted by custom power companies in Colorado, but the rate of The Central Colorado Power Company, which is the largest of the several companies mentioned, is as follows:

FIXED CHARGE.

Per month Per H. P. of Maximum Demand.	
For the first 100 H. P.	$3.25
For the next 400 H. P.	2.25
For the next 500 H. P.	1.75
For all additional H. P.	1.00

ENERGY CHARGE.

Add for all energy used as shown by meter 13 mills per kilowatt hour for the first 40,000 kilowatt hours used each month, and 5 mills per kilowatt hour for all additional energy.

This rate works out as follows: If the maximum demand be 100 horse-power, and the annual load factor 60 per cent., the cost of power is then $90 per horse-power year, and the cost of $90 per horse-power year at 60 per cent. load factor is 2.3 cents per kilowatt hour, a kilowatt being the same amount of energy as in 1½ horse-power, and a kilowatt hour being the amount of energy involved in the use of 1½ horse-power steadily for one hour.

If the maximum demand be 200 horse-power, and the load factor 60 per cent. the cost of The Central Colorado Power Company's service is about $72.00 per horse-power year, which is the same thing as $1. cents per kilowatt hour.

If the maximum demand be 500 horse-power, and t load factor 60 per cent., the cost of the Central Col ado Power Company's service would be $57.00 p horse-power year, or about 1.45 cents per kilow hour.

It will be found that these rates are even lower th those given to custom power users throughout t East, where the cost of generating power is natura much less than in our mountains, because of both c matic and geographical conditions.

An instance of the saving in mining costs effect by this power service is given in the case of the lar Iron-Silver Mine at Leadville, where, after conversi from steam to electric drive, the manager reports saving of 48 per cent. in the cost of pumping, and 38 per cent. of his hoisting costs.

In the mining and milling of low grade ore bodi power becomes a very high factor in the total co A former manager of the American Zinc Extracti Company's custom mill at Leadville (mill treated l grade complex lead, zinc and iron ores) reported th in his operation the cost of power constituted 25 p cent. of his total cost. The availability, therefore, a reliable and cheap power is certain to do much ward the developing, mining and milling of low gra ore bodies that makes most for substantial and pr perous mining communities.

ELECTRIC SMELTING OF ZINC-LEAD ORE I NORWAY AND SWEDEN.

The electric smelting works at Sarpsborg, Norwa and Trollhattan, in Sweden, have been taken over an English company. At these works it is intend to treat complex sulphide ores and the mixed s phides of lead, zinc, copper and iron so frequent found in many parts of the world, but at present little commercial value in consequence of treatme difficulties. An abundant supply of hydro-electri power will be available in these works, as the countri are well supplied with rapid rivers and large lakes high altitudes. Reports by Messrs. J. C. Moulden a F. W. Harbord have been supplied, which state th the electric furnace employed has carbon electrod and the heating and melting of the charge is effect by resistance with a current of low voltage. In t first furnace 2.8 tons of roasted ore can be treated 24 hours. The horse-power per furnace is 350, and Trollhattan the cost of power by the hydro-electr company runs to 30s 3d per horse power year. The are 11 furnaces. The roasted ore, coke or anthraci dust, and flux are charged into the furnace, and mo of the zinc and some of the lead is volatilised. T greater proportion of this is condensed as a cru spelter with high lead content, but much of it is pr cipitated as metallic fume and oxide, and has to be r turned to the furnace in subsequent charges. T lead that is not volatilised is reduced as liquid met and it contains a considerable proportion of the silv Matte is formed of the iron, copper, and sulphur, present in the ore, and some of the lead, zinc and silv passes into it. Some lead also escapes with the sla The crude zinc is refined in other electric furnaces, a the final zinc product is exceptionally pure, averagi 99.9 per cent., commanding a premium price in t market. During Mr. Harbord's experience at Tro hattan 518 tons of roasted Broken Hill slime, 19 to of calamine, 22½ tons of zinc-lead powder, produc

viously produced 160.8 tons of crude zinc, which, refining, yielded 112.4 tons of pure zinc, 24.7 tons lead and 36 tons of zinc-lead powder. In addition, tons of lead tapped contained 141 ozs. of silver ton and 17 tons of "leak" lead, assaying 27 ozs. silver per ton, was recovered, also 9 tons of skimmings containing lead, zinc and silver. The recovery from the various sources was 64 per cent. of the zinc, 74 per cent. of the lead, and 46 per cent. of the silver, not counting the metal in the powder.

Character of Ore Deposit and Probable Milling Methods at Porcupine.

(Written for the CANADIAN MINING JOURNAL by Louis W. Huntoon.*

The following article on the Porcupine district of Ontario is intended primarily to discuss the ore deposits and future prospect of the camp, the character of the ore, and the probable milling methods which will ultimately be introduced.

Location and Extent.

This district, which has attracted such world-wide attention, due to the phenomenal rich strikes of gold ore, can now be reached by rail from Toronto, a distance of 473 miles. It is located north of Toronto, North Bay, and Cobalt, on the Hudson Bay slope of Northern Ontario. The district is many miles square, although most of the prospecting and development work has been confined to the township of Tisdale.

History.

Previous to three years ago the district was a vast wilderness and little was known of it. The main part of the camp is situated along an old portage route used by the Hudson Bay Company officials for a couple of centuries. In 1896 Mr. E. M. Burwash, and again in 1899, Mr. W. A. Parks, noted the occurrence of quartz veins carrying traces of gold. These observations were published by the Bureau of Mines, with the remark that the country was a promising one for the prospector. In 1906 some prospecting was done near the Hollinger vein, but evidently as no free gold was seen, and as no assays were made, work was abandoned, and it was not until 1909 that the spectacular discoveries were made on the Dome prospect by J. S. Wilson. This discovery caused a rush to the district, and in a few weeks practically all of Tisdale (6 square miles), and a large part of the adjoining townships were staked out in mining claims. These spectacular surface showings inflated the value of claims to such an extent that they changed hands at mine prices before the properties had been prospected and caused such remarks as: The price at which properties are held is determined by the number of specks of gold, and in some cases the price appears to be $0,000 per speck. One broker in Toronto stated that he had no trouble in selling properties, providing he could guarantee a cropping of rock, which is significant, inasmuch as many claims were located in swamps or on land which had a very heavy overburden of soil. During the excitement mining companies were organized and capitalized in the millions, and from the favourable reports published on the camp and by mining companies, it was easy to dispose of such stock at a handsome profit to the promoters. It is to be hoped that some day in the near future, laws will be enacted to protect the public against investments which are so over-capitalized, by requiring the promoters to furnish security, such as mortgage bonds, together with the stock for all cash invested, and that these bonds shall be paid off from the first profits derived from operating. Much of the stock of the Porcupine camp, as well as the stock of other mining districts, is worth no more than the paper upon which it is written. Only last summer many companies allowed the information to be circulated that mills were being designed and the machinery ordered, on which information the price of the stock was advanced. There were but two mines at the time these reports were circulated which had sufficient ore developed to warrant the erection of mills.

Last winter all supplies, including machinery for two mills, were hauled into the camp over the frozen lakes and snow, and this spring at the "break up" it was almost impossible for a man to walk into the camp. This fall opened with a railroad into the camp, and the Government is to be complimented on the speed with which this tremendous undertaking was accomplished. The Government is also building wagon roads through the forest, and by next summer it should be possible for a visitor to be transported by carriage around the camp. The forest fires of the summer destroyed both the Hollinger and Dome mills. The latter company duplicated its order, and the second mill has been delivered by rail to the property, and should be operating the early part of 1912.

Prospecting, Exploring and Development.

The camp is but two years old, and during this period a large amount of money has been invested in prospecting, exploring, and developing.

The method of prospecting, similar to that of the Cobalt district, consists of surface trenches and stripping. When a vein is located it is stripped and examined for specks of free gold. The surface showings are carefully guarded, as it was on these that the properties and stock were sold. At one property visited the specks were so few that it was necessary to use a tape measure to locate them, and still the reports received in New York from the manager of this property were most favourable. Another property with a surface showing of a small pocket of quartz carrying free gold, was selling last summer on the New York curb at a valuation of over $800,000. The exploration work on this property consisted of a shallow shaft located in the country rock. The ore body showing on the surface has not been found in depth after further sinking and crosscutting, although another pocket of quartz carrying values has been developed. The results from this exploratory work ap-

*Consulting Mining Engineer, 42 Broadway, New York.

parently have not been favourable, as the value of the property has decreased on the curb to $309,000.

After the veins are discovered, and sufficient money raised to explore the property, shafts are sunk. A rule which should always be followed on such uncertain deposits in exploration work is to stay with the ore. Only in a very few instances has this rule been followed. The inference is that the promoters, sinking shafts in the country rock, did so for stock speculation and for fear of destroying the beautiful showings of free gold. Diamond and shot core drills have been largely used throughout the camp, and the information derived has been most valuable.

The two principal properties which have been developed are the Dome and Hollinger mines. These properties may be classed as mines, and the capital stock of the companies will be returned with interest to the stockholders. There are only a few other properties upon which development work has been done, and before classifying them as mines, considerable more work will be required with the possible exception of one or two.

Ore Deposits, Future Prospects of Camp.

The ore deposits are of the fissure type, occurring in the Keewatin schists, Huronian conglomerate, and in Langmuir township, a contact vein between granite and schist is reported assaying from $4 to $8 per ton. The rock formations of Porcupine have been subject to much greater metamorphism than in Cobalt, resulting in some deposits of much greater extent. The Keewatin has been altered to schists and in places so badly crushed that it resembles a conglomerate. The veins forming the ore bodies cover a wide area, occurring in groups along certain lines of fissuring, although often isolated. In the township of Tisdale the results of the prospecting have shown three distinct areas.

In the vicinity of Pearl Lake the line of fissuring extends for about three miles, and has a general strike to the northeast. The Hollinger mine and some good prospects which warrant thorough prospecting, are on this line of fissuring. On this same line are also many small isolated veins which may furnish sufficient ore for a centrally located customs mill, but very few properties will warrant the erection of individual mills. A recent report on one of these properties contains the following: "The surface has been partially prospected by approximately 10,000 feet of trenching and stripping. Twenty-three veins have been discovered." This statement reminds one of the annual reports issued by the Cobalt mines and tends to prove that the area of fissuring is wide, that the individual veins are scattered, and most of them will probably be limited in extent. Before such deposits warrant the building of mills, they should contain sufficient fully developed ore to repay such an investment.

Southwest of Porcupine Lake the surface shows that the formation has been badly crushed and fissured. In this district we have the Dome mine, where the disturbance is over an area of six hundred by eight hundred feet, producing the large deposit of ore developed on the Dome property. This ore body consists of quartz veins in the disturbed formation. The general strike of the formation is north of east, and on this line, and also to the northeast, small scattered veins have been discovered, but only a large amount of stripping, followed by exploration work, will determine if they are of any commercial value.

North and northwest of Porcupine Lake we have our third area of fissuring. The general strike is east and west. The ore bodies in this section consist o scattered deposits of comparatively limited tonnage which, when developed, may furnish sufficient ore fo a customs mill. In June the surface indications wer that no one property would warrant the building of mill although further exploration work may possibl develop a large mine.

Character of Ore.

An examination of the veins and ore of the distric indicates that the original fissures were filled witl quartz containing no values. At some later period th quartz was again fissured and fractured, and the gol deposited together with quartz in the interstices. I the gold quartz we generally find ankerite, which ap pears to have been one of the important precipitatin agents. It is a fact that the greatest quantity of gol is along the fracture planes, which in some ores, suc as Rea, gives a streaky character to the ore. The dis tribution of the gold is very irregular and occur chiefly along one or both walls of the quartz, provid ing it has not been thoroughly fractured. The un fractured portions of the veins, so far as could b learned from inquiries and observations, contain n values. The pyrite associated with the quartz, ac cording to the Government report, is auriferous and one sample assayed $10.40 in gold. The mine oper ators in the district state that the pyrite contained i the gold quartz is auriferous, but that that contained i the country rock is not. The irregular mineralization o the veins is responsible for the statement of engineer and geologists, that the district will develop into a low grade camp. The ore as hoisted will probably b low grade, but there is no reason why the "run o mine" should not be hand picked and a high grad ore sent to the mill, thereby reducing costs and increas ing capacity and efficiency.

Milling.

Before a large milling plant is erected, it is much safer to erect and operate a small and complete test ing plant during the development of a mine, and from the information derived from this plant to design the large mill. It is practically impossible on most ore bodies to select one or two car loads of representative ore to be tested in an ore testing plant, as the samples should be taken from all portions as the development advances. If thorough tests are not made before the erection of the final plant, it is often necessary at a great expense to rearrange the entire plant, adding to and taking from the plant installed. The general character of the ore and ore deposit will often furnish valuable information, and especially so when compared with like ores of other districts. It is from observations made in the district and comparing the work of other districts that the following suggestions are offered.

The milling method adopted by the Dome mine, as published in the CANADIAN MINING JOURNAL, is as follows: Hoisting, breaking through two gyratories, and conveying to stamp mill bins. The second operation consists of stamping, plate amalgamation, classifying, tube milling, plate amalgamation, classifying, and dewatering. The third operation is cyaniding in Pachuca tanks, and the last is the recovery and refining of the gold from the cyanide solutions.

It would appear that the first two operations might be altered, thereby greatly increasing the capacity and efficiency of the mill.

Preliminary Hand Dressing.

The character of the deposits are such that a large amount of country rock or waste rock must be mined

with the ore. If this waste rock can be distinguished from the gold-bearing quartz, and presumably it can, it is far less expensive with such ores to discard the waste by hand than to put it through the mill. Specimen ore can be recognized and it may also be advisable to sack this both underground and on the surface for special treatment, as is done at various properties.

Reviewing hand sorting operations in various large camps we find the following: At the gold mines in South Africa, where more attention has been given to hand sorting of gold ores than in any other district, the ores are sized before picking, so as to increase the efficiency. The amount of waste discarded by hand in this district will average approximately 20 per cent. A great many of the mines are discarding over this amount. At the Ferreira mine, in South Africa, a net saving of $1,167,000 was made in ten years, and during 1903 and 1904 the annual net saving was $125,000. The annual reports from all of the mines in this district show large savings from hand dressing. In the Tonopah district of Nevada, where wages are four dollars per day, special ore sorting houses have been erected. One of the first of these was that erected by the Tonopah Mining Company, where 11 per cent. of waste is discarded at a cost of 80c. per ton of waste. The ore sorting consists of feeding the run of mine to a 1½-inch grizzly, from which the oversize is discharged to an ore bin. The ore from here is fed to a picking apron just below the bin gates. This arrangement costs practically nothing to install, as it is only a slight addition to the ore bins and is very efficient. The Tonopah-Belmont plant is of recent construction and contains ore sorting belts. Such an arrangement, the advantage of which is closer sorting, is more expensive to install. From 15 to 20 per cent. of waste is discarded at a cost of 68c. per ton of waste. At the West End mine very close sorting is required, as the ores are shipped to the smelters. The cost at this plant is $1.57 per ton of waste discarded. In the Cripple Creek district of Colorado, where labour is also high, special ore sorting plants have been erected, and it is due to these plants that many of the mines have been successfully operated.

At the following properties both high grade ore and waste rock are separated by hand: At the North Star mines in California, the rich gold ore is picked out by the specimen bosses and run through the mill at the end of the month just before making the clean-up. In the Cobalt district the waste rock is discarded by hand and the high grade ore is carefully picked out and sacked for shipment or for special treatment. In the lead silver district of Idaho, we find that hand dressing has only been introduced within the last few years and that it has been most successful in increasing the capacity and efficiency of their plants by discarding waste rock and sacking the high grade lead-silver ore underground and also sorting it out from the picking belt.

In the above districts, where labour is high, hand sorting has been most profitable, not only reducing the cost of operations, but also increasing largely the capacity of the mills. From the character of the deposits in the Porcupine district, hand dressing should be very carefully considered, and with the smaller mines it is the only method by which they can be operated at a profit.

Crushing and Pulverizing.

Rapid progress is being made in fine crushing, and the flow sheets of gold mines are being altered the world over to increase the capacity of the stamp mill. For several years past the weight of stamps in use in South Africa has been gradually increased from 1,000 to 2,000 pounds, whereas in this country the increased weight is not so pronounced. At the Dome mine it is the intention to use 1,250-pound stamps, which, with a few exceptions, are the heaviest in use in America. The use of coarser discharge screens to increase the capacity is very common, and this, in turn, necessitates the installation of some form of pulverizer. Tube mills taking the feed from the stamps have been in favour, but lately the Goldfield Consolidated Company of Nevada has installed Chilean mills between the stamps and tube mills. The installation of six 6-foot Chilean mills, at a cost of $75,000, has increased the capacity of 100 stamps from 6 tons to 8.5 tons. The installation of stamps and tube mills, together with the necessary changes for this increase in capacity, would have cost $175,000. The following comparison of costs is interesting:

100 stamps, crushing 8.5 tons, through 4 mesh, require 10 tube mills to give the desired product, whereas if the stamps are followed by six 6 foot Chilean mills crushing through 16 mesh, only 5 tube mills are required. The costs are estimated as follows:

	Two-stage Reduction.	Three-stage Reduction.
Stamping	13.4 cts.	13.4 cts.
Chilean mills	.....	10.6 cts.
Tube milling	30.0 cts.	16.6 cts.
Total, per ton	43.4 cts.	40.6 cts.

Not only has the installation of Chilean mills and accessories cost $100,000 less, but the cost of operating is also 2.8c. less per ton.

Concentration.

The Porcupine ores carry a small percentage of auriferous pyrite which is liable to increase with depth. Experience has shown that most ores containing free gold and auriferous pyrite give a higher recovery by concentrating and amalgamation and treating the sand and concentrates separately.

Reviewing the practice in other camps, we find the following: At the Perseverance mine, Juneau, Alaska, the gold ores carry only 2 per cent. of pyrite. These ores are stamped, amalgamated, and concentrated. The concentrates assaying $30 per ton are then amalgamated in pans and re-concentrated. The results at this property are reported to be most satisfactory. At the Alaska-Treadwell mill, on Douglas Island, the ores up to a year ago were stamped, amalgamated, and concentrated, and the concentrates, assaying about $30 per ton, were shipped to a smelter. Since then the concentrates have been pulverized in tube mills, passed over amalgamating plates if necessary, and cyanided, resulting in a large saving on the cost of treatment per ton. The ores on the Goldfield Consolidated mine of Nevada have given considerable trouble, due to a large percentage of the gold being carried in pyrite, which could not, without special treatment, be recovered by amalgamation or cyaniding. Their original mill consisted of stamping, amalgamating, tube milling, concentrating, and cyaniding of the tailings. The concentrates were shipped to a smelter at a heavy cost for freight and treatment. After considerable experimenting, it was found by first treating the concentrate with an acid solution, that 94 per cent. of the gold could be recovered by cyaniding, thereby reducing the cost ma-

terially. This special process is in use at the present time.

The advantages to be derived by concentration before cyaniding, are increased capacity of the plant, very often a slightly increased extraction, and increased profits. By concentrating after amalgamation any coarse grains of gold which are coated with a film, preventing amalgamation, and pyrite containing gold, are removed. This leaves a clean sand containing fine gold, which can be run through the cyanide tanks rapidly with a high extraction, thereby decreasing the number of tanks required. The concentrates which contain gold not amenable to amalgamation can then be shipped to the smelter or be given a special treatment and a high extraction obtained.

Theoretical Example.

The following theoretical example may serve to bring out the advantages to be derived by preliminary hand picking and concentration of ores. Given a gold ore assaying $10 per ton, from which 90 per cent. can be recovered by amalgamation and by cyaniding of the tailings. The capacity of the plant to be 100 tons per day, and four days to be allowed for cyaniding. The plant will then require a tank capacity of 400 tons. Allowing $2 for mining and $2 for milling, our net daily profits will then be $500.

If from the above ore 25 per cent. of waste rock, assaying $1 per ton, can be hand picked at a cost of $1 per ton of waste, we can then increase the ore mined 33⅓ per cent., or from 100 to 133⅓ tons per day, and from this we will have 100 tons to feed to the mill, assaying $13 per ton. Assuming that a recovery of 50 per cent. can be made by amalgamation, that 4 per cent. of concentrates, assaying $30 per ton, will be produced, that the sands free from pyrite and coarse gold can be cyanided in two days with a recovery of 95 per cent. of the gold contained in the sands, that a recovery of 90 per cent. of the gold in the concentrates can be extracted by a special treatment requiring six days, at a cost of $1 per ton for this special treatment, we then find from our table that our profit has been increased $247.83 per day, and that a tank capacity of only 216 tons will be required, as against 400 tons tank capacity by treating direct.

Conclusions.

In conclusion, the writer wishes to say that this article is not written to criticize the mills being designed and erected by companies in the Porcupine district, who are employing metallurgical experts, but merely to call attention to certain observations made when visiting the camp in June. Hand dressing has not been practised to any large extent in America until within the last few years, as it has always been assumed that the labour costs were entirely too high. Abroad, and especially in Germany, hand dressing is practised on a very large scale. With properly arranged plants hand dressing of waste rock from gold ores is far less expensive in most cases than milling. The references made to crushing and concentrating are improvements which have been introduced in gold milling within the last few years.

*Recovery by amalgamation.

SPECIAL CORRESPONDENCE

ONTARIO.

Cobalt, Gowganda, and South Lorrain.

Sir Henry Pellatt has secured a three months' working option on the 40-acre claim of the Dominion silver mines, near North Cobalt. A shaft has been sunk 30 feet on one of the veins and some time ago it was reported that silver had been discovered in it. A small plant will be installed and vigorous development ensue. It is also reported in this same section that the Santa Maria Mining Company, which has the Green Meehan under lease, has struck another body of ore.

The report of the Buffalo mill for the month of September reads: mill ran 550 hours, ore milled, 4.116 tons; average assay, 29.22 ounces; ounces recovered, 97,972; ounces of silver paid for during the month but shipped previously, 106,726.

In a report to the head office of the Trethewey, Mr. Chas. O'Connell reports a considerable improvement in the physical condition of that property. He states that while the mill is treating an average of a hundred tons per day, yielding approximately 2,000 ounces of silver, there is now in sight three years' supply of milling ore under ground and one year's supply on the dump. From the beginning of the year to October 31st, there had been shipped 491 tons, containing gross value of 299,121, as compared with 423 tons of gross value of $275,070 during the same period of the previous year. The financial position of the company on November 10th was: cash in bank, due from smelters, and ore on hand, $104,695.

The Beaver Consolidated has declared another dividend, payable on December 15th. It is of 3 per cent., and calls for a disbursement of $60,000. The Beaver paid its first dividend after two and a half years of work on May 15th, and has now paid 8 per cent., or, altogether, $170,000.

A. H. Brown, formerly of the Coniagas mine, Cobalt, and later manager of the Pike Lake Mining Company, at Swastika, has taken up his duties as manager of the Hudson Bay mine at Cobalt.

The McKinley-Darragh-Savage will pay its usual 10 per cent. dividend on January 1st. During the past year the McKinley-Darragh has paid 50 per cent. to shareholders, and has now returned 96 per cent. of its capitalization, or $2,156,521.

The shipments from the Cobalt camp for the month of November read: McKinley-Darragh-Savage, 258.46 tons; Coniagas, 145.86; Cobalt Lake, 162.72; Crown Reserve, 48.93; Nipissing, 358.02; Buffalo, 87.73; Cobalt Provincial, 25.05; Hudson Bay, 97.32; La Rose, 252.36; Right of Way, 41.17; Cobalt Townsite, 23.59; Temiskaming, 67.78; Chambers-Ferland, 32.00; Colonial, 22.25; Kerr Lake, 111.97; Trethewey, 29.88; O'Brien, 32.02; Drummond, 90.00; total, 887.25. The only heavy shippers of low grade ore last month were the Nipissing and the Drummond, the great bulk of the ore being concentrates and high grade ore, with about $190,000 in bullion.

Last month the Nipissing produced $225,907 net, and shipped $248,980. Of this production $90,407 was of mine ore, while $158,573 was contained in the bullion from the high grade reduction plant. While there were no new developments, the underground work on the property is proceeding very satisfactorily.

Porcupine and Swastika.

While every one is waiting expectantly for the long delayed report on the Hollinger, very favourable development is proceeding at the Miller Middleton, the next Timmins-McMartin-Dunlap flotation likely to go on the market. For 125 feet the drift at the 65-foot level is in an ore body of quartz and schist which on the first sampling ran $8 to the ton. The face of the drift is still in values.

For the last month the market has hung fire until the publication of Mr. Robbins' report. As this is the first occasion on which the property has been thoroughly sampled, it is awaited with the greatest interest. Meanwhile the work of construction is proceeding. Nearly all the camp buildings have been completed, and the mill is now up to the second story, although most of the machinery is not yet on the ground. Underground the position remains very much as it was four or five months ago. This is to say, there is 1,100 feet of drift in ore on the 100 foot level, with an average vein of eight feet. On the second level about 237 feet have been opened up, with values and width much the same. There is one more important lead located and opened up for 50 feet on the first level. This was 24 feet wide where it was cut, and as the whole of the drift is in solid quartz it is difficult to arrive at an average width. Another ore body cut consists of about a foot of quartz in a mineralized schist zone, and here it is the schist that carries the values. There is very considerable dissatisfaction with the progress that has been made lately on the Hollinger Extension branch. The Timmins syndicate, which is providing the money for the extension, was promised the railroad in at their townsite by November 1st at the latest, and now it is very probable that it will not reach that spot by February or March 1st. Many companies held back their orders for machinery until they saw that it would delay them very considerably if they did so, and they are now hauling over the roads.

In its No. 4 shaft the McIntyre has cut its vein at the 200 foot level. It is reported that the vein is at this particular point twenty feet wide, and that it runs $19 to the ton. Work is proceeding fast with the construction of the ten stamp mill, the excavations have been made and all the machinery has been ordered. Meanwhile a considerable amount of ore has been put in sight.

The Bouzan properties on the boundary line between Whitney and Cody have been sold to the Intercolonial Gold syndicate, an association of Belgian capitalists.

The vein on the Hughes Porcupine mines at 20 feet has dipped back into the shaft. It here shows eight feet of quartz and contains a considerable amount of visible gold. Thirty men are employed in sinking the shaft and in putting up camp buildings.

Plans have been prepared for the development of the 14 claims owned by the Hollinger Reserve and a plant is being installed. To date merely surface work has been undertaken, but the veins so far uncovered are of good width and show gold.

The shear zone on the Davidson property at a hundred feet proves to be as extensive as on the surface. For a hundred feet the drift is in quartz and schist. Nothing has as yet been made public of the average values at this depth, but there is a considerable amount of gold visible in the specimens brought from below.

C. W. Duncan, for a Toronto syndicate, has optioned the Lilly claim at Swastika, and also two claims to the northeast of the Lucky Cross. Development work on the Lucky Cross at Swastika has yielded very satisfactory results. Down to about the 50-foot level, where the vein dipped out the shaft, there was a remarkable showing of visible gold in a quartz lead that was from four to five feet wide.

An average rate of a hundred feet a month is being made on the Pearl Lake property. During one week over 25 feet were drilled and shot out. The shaft is rapidly approaching the 200-foot level, where the first level will be cut.

The letter of H. L. Taylor, the new president of the Imperial Gold Mining Company at Porcupine, states that "within a year we believe we will have a mill and a mine." The secretary-treasurer's report shows a balance of $3,958 in the treasury and 648,000 shares intact in a $2,000,000 company. Two crosscuts are being driven at the 100-foot level.

The Boston Development Company is opening up its claims in Deloro, where it reports good results from its surface prospecting. Camps have been erected and eighteen men are now employed.

The Hon. W. H. Hearst, Minister of Lands, Forests and Mines, has promised, among many other things, to the miners and prospectors that the townships of Ogden and Deloro shall be taken out of the Temagami Forest Reserve, so that a prospector can get a patent for his claims. He has also promised more and better roads for the mining districts, and that permits to prospect in the Reserve should be issued at the Recorders' offices in the various districts where these sections are, instead of at Toronto.

Mr. Oscar Bergstrom has taken charge of the Rea Consolidated in place of Mr. Kingsmill. Mr. Bergstrom commenced his career in the mining world at an iron property in Sweden. The first camp he saw in America was Butte, and he has since travelled to nearly all the precious metal camps of the western States. He has held important posts at Leadville, Colo., in Alaska, and he reached this country from California, where he was in charge of the Calaveras gold mine, and also the Calaveras copper mine.

It is now known that while the vein at the 300 foot level of the Rea is from 35 to 40 feet wide, the values run discouragingly low.

Since the good prospecting areas round Porcupine became delimited the army of mineral seekers in Northern Ontario are roving still wider and wider afield. There are parties covering all the good ground between Porcupine and Sudbury, and there is a little rush to the Hurricanaw River, south of the Transcontinental. Also mild excitement has been caused in Cochrane by the statement that Chief Commando had discovered quicksilver on the Ground Hog River while out prospecting. Several men of some experience have seen samples from this section, and declare that it is promising. Quicksilver is found in the Nipissing ores in uncommercial quantities, which lends some colour of probability to the statement of the Indian.

BRITISH COLUMBIA.

On November 15th the Canadian Mining Journal included in the General Mining News it printed, the following news item: "Fernie, Nov. 3.—The Riot Act was read in Fernie last night by Mayor Bleasdell after a violent outbreak on the part of the miners, when a train arrived from Coal Creek with men on board who had gone to work in the mines without waiting until the agreement now under consideration at Frank had been signed and ratified. Large numbers of miners were on hand when the train reached here, and the men who had worked were greeted with hisses and derisive language. One man was hit upon the side of the face with a stone thrown by some one in the crowd." As no mention was made, on the other hand, of the general good behaviour during a long season of suspension of work of the great majority of the mine and coke-oven workers, common justice to them would seem to make it desirable that the following "Open Letter to Dr. Warnock, M.P., Ottawa," written by Mr. J. W. Bennett, editor and manager of The District Ledger, Fernie, the official organ of District No. 18, United Mine Workers of America, be also printed in the Canadian Mining Journal. It may be mentioned that copies of this letter were sent to Hon. Robert Rogers, Minister of the Interior (who has been credited with having brought together the Operators and Mine Workers and arranged a basis of settlement of the strike): Hon. T. W. Crothers, Minister of Labour; and Mr. A. S. Goodeve, member for Kootenay in the House of Commons. Under date, November 21, Mr. Bennett addressed Dr. Warnock as follows:

"Dear Sir,—According to press notices we see that you have put in notice of questions to be asked regarding the recent disturbances in Fernie, and as the probabilities are that the reports you have obtained relative to this subject may have been more or less garbled, we fell it incumbent upon us as representing the mine workers throughout District 18, to state the case exactly as we know it to have existed.

"From April 1 to October 31 the quietness and respect for law and order shown by those out on strike was a surprise to everybody, more especially so when is taken into consideration the cosmopolitan character of those involved. We may say that every coal region of Europe has its quota of representatives, and in addition thereto a large element from southern Europe were employed here as labourers—such as Italians, Montenegrins, Roumanians, and other natives of non-coal-producing countries. The disturbances that occurred were exceedingly trifling and have been throughout, even when it was deemed necessary to read the Riot Act.

"When the report was telegraphed throughout the length and breadth of the land that the Hon. Robt. Rogers had settled the strike men came from widespread parts only to ascertain the news was premature. This, as was natural, had a tendency to create a feeling of resentment. Moreover, there was not a single piece of property belonging to the coal company destroyed or in any way injured. A few panes of glass were broken in the house occupied by the Barr family, who had received rations from the mine workers' organization until October 31 and then went to work. Four negroes who had been given permission by the local magistrate to carry firearms were also hooted and jeered at when they came off the train, one of them discharging his revolver, which, fortunately, did no damage. Another individual, named Potter, who had received consideration at the hands of the organization, followed the example of the Barrs.

"When the Riot Act was read four policemen of the city force were quite sufficient to prevent any congestion of traffic, and although there was a large crowd of people gathered together, the spirit prevailing was more of curiosity-mongering, attracted, as usual at a time when idleness prevails, to see what was going on. The reading of the Riot Act was treated more as a farcical joke.

"With the exception of the above incident and the occasional throwing of snowballs when the police escort of over 40 men were accompanying five who had been to work, there was really no disturbance.

"The above is a plain statement of facts of which you may make any use you see fit and make known the name and position of the writer."

Cariboo.—It has transpired that the placer-gold mining season of 1911 in Cariboo district was to some extent disappointing. Cold weather in the spring made a late opening of the season; then the snow melted quickly when the summer set in; finally, unusually dry weather was experienced throughout the autumn. These things combined to make the gravel-washing season very short, with the result that the quantity of gold recovered was smaller than had been expected. However, the number of properties on which placer-mining was done, and the additional construction and development work carried out in preparation for future operations, were both satisfactory, indicating that a larger total yield of gold may reasonably be looked for in the early future.

Atlin.—While detailed information relative to hydraulicking operations on the several gold-bearing creeks in Atlin camp has not yet been received, a statement has been published to the effect that less gold was removed during the season lately closed than in that of 1910. The reason assigned is that some of the larger operators were occupied during part of the season in making improvements and extensions to plant, water-supply systems, etc., so did not wash so much gravel as they might otherwise have done. The betterments made, though, are stated to make the outlook better for the recovery of more gold next and following seasons.

Slocan.—The Standard Silver-Lead Mining Company's concentrating mill, built near Silverton, on the shore of Slocan Lake, is now operating. The mill has a crushing capacity of about 200 tons per day, but as yet concentrating machinery for only half that quantity has been put in. A considerable proportion of the ore is sorted out after having been crushed and is shipped to the smeltery in its crude shape, being high-grade ore. All the surface improvements decided upon when the Standard property was acquired from Messrs. Aylard and Finch by the company nearly a year ago have been completed. These include putting in a water-supply system for operating compressor plant and concentrating mill, an air compressor, for machine drill and other power purposes at the mine, the concentrating mill above-mentioned, and an aerial tramway from the mine down to the mill, a distance of about 8,000 feet. Shipment of ore and concentrate to the smeltery at Trail will, it is expected, be regularly maintained from now on.

Nelson.—At a meeting held at Nelson on November 21, a number of resolutions were passed with the object of advancing the interests of those engaged in mining lead and zinc ores. The gathering, though not as large nor representative as some mining conventions held in the province in earlier years, was attended by a sufficient number of men prominently associated with lead and zinc mining to make the recommendations of the meeting worthy of the serious consideration of the Federal Government. These resolutions, as reported in the local newspaper, included on urging the appointment by the Dominion Government of a commission to enquire into the method best suited to encourage and protect the zinc-mining industry and to consider the question of bonus or award and rendering financial assistance to any person or persons who shall "devise and carry to commercial success works for the reduction and refining of low-grade zinc-lead ores of this country which are not at present amenable to the ordinary methods of zinc concentration." Another asked the Government "to create a portfolio of mines, the Minister to devote his attention entirely to the industry," and to strengthen the case for this proposed most important change in the policy of the Government, the resolution was moved by a local lawyer, and seconded by a prominent fruit-grower, neither actively engaged in mining. The Dominion Government may be expected to regard so serious a departure from the present order of things as at least worthy of the earnest and united support of a far larger number of men closely connected with the operations of the mining and smelting industries than were present at the meeting under notice. The appointment of Messrs. W. E. Zwicky, Oscar V. White, A. J. Becker, and T. W. Bingay on a committee to investigate the situation in regard to the desirability or otherwise of petitioning "for protection on lead and zinc, either in the shape of duty or bounty," is a matter for congratulation, for they are men deeply interested in this question, being actively engaged in connection with mining or smelting lead-zinc ores, and can speak whereof they know. Finally, the opinion may be here expressed that reference of these matters, relating essentially to the interests of the mining industry, to the Conservative convention, at that time sitting in New Westminster, for endorsement by men, few of whom know anything at all about the important subjects thus referred to them, was a move not worthy of the mining men of the country who, if they have a good case for support from the Federal Government in connection with one of the largest industries of the West, might reasonably be expected to present it on its merits, and not make it a subject for action by any purely political organization.

Coast.—It is stated that the Canadian Mining Operators, Limited, a Vancouver development company, of which Mr. Robert R. Hedley is technical adviser and mining engineer, has acquired twenty sections of coal land adjoining that of the B. C. Anthracite Company, in Ground Hog district, Upper Skeena.

Messrs. Harris Brothers, who are largely interested in the American Boy group of eight mineral claims, situated in Ninemile Mountain camp, in the Hazelton (Skeena River) district, lately stated for publication that they think the Hazelton district contains more properties giving promise of becoming producers of rich ore than were known in Slocan district at a similar stage of development eighteen years ago.

The Natural Resources Security Co., Ltd., has lately been advertising that "An immense body of anthracite coal exists at the head waters of the Skeena, about 150 miles north of Hazelton. . . . It is stated that good coal seams are known to underlie over 2,100 square miles of territory, and that the estimated capacity of the field is 43,000,000 tons per square mile." As this works out at an aggregate content of 90,300,000,000 tons of coal, it may be pointed out that Mr. D. B. Dowling, of the Geological Survey of Canada, one of the most noted coal geologists of the Dominion, in a paper he contributed to the last Annual Meeting of the Canadian Mining Institute, gave a table showing an estimate of only 1,351 square miles of coal-bearing territory in the whole of British Columbia, and an estimated aggregate coal content of 40,221,000,000 tons.

GENERAL MINING NEWS.

QUEBEC.

Montreal, Dec. 4.—A meeting of the shareholders of the Canadian Venezuelan Ore Company, Limited, was held to-day at the Windsor Hotel. This company, which consists of Montreal, Halifax, and Toronto capitalists, has secured large deposits of iron ore of bessemer quality on the Orinoco River, Venezuela. Mr. W. B. Ford, formerly in charge of the mines of the Dominion Iron & Steel Company at Wabana, Newfoundland, is the resident manager of the company in Venezuela.

The officers elected at to-day's meeting were as follows: F. P. Jones, president; Sir William C. Van Horne, vice-president; Sir Max Aitken, G. B. Bosworth, H. S. Holt, Hon. A. K. Maclean, M.P., G. Fred Pearson, John D. Patterson, and W. D. Ross, directors.

Asked as to when the company expected to commence operations, Mr. F. P. Jones, the president, said:

"We have nearly all our machinery on the ground now and with the competent staff now in charge at Imotica, I expect we will be shipping ore early in the New Year."

ONTARIO.

Cobalt.—The Northern Ontario Light and Power Company, Limited, has been formed to take over the properties of the Cobalt Power Company, Limited, and its subsidiary companies, and the Cobalt Hydraulic Power Company, Limited. The company furnishes power and light in the towns of Cobalt, North Cobalt, Haileybury, New Liskeard, Cochrane, and Porcupine.

Porcupine.—Directors of the Temiskaming have been inspecting the North Dome property, the controlling interest in which has been acquired by the Temiskaming Company. A circular has been issued to Temiskaming shareholders, giving the details of the deal and announcing the passing of the Temiskaming dividend for the current quarter. The deal is sub-

stantially as The Star gave it a couple of days ago.

The Temiskaming take over 138,000 shares, for which they will pay $229,000, or approximately $1.66 per share. This amount is payable in instalments extending over 13 months.

The North Dome is capitalized at $2,000,000, or 400,000 shares at $5 per share. There are 171,459 shares in the treasury.

The Temiskaming directors announce that it is the intention to push developments on the property, and that arrangements have already been completed for the sale of sufficient of the treasury stock at $1.66 per share, to provide necessary funds for some months to come.

Porcupine.—The most interesting news that has come out of Porcupine for some time was a despatch received by the Pearl Lake Gold Mines, Limited, recently from G. W. Thomson. It gave the first news of values at depth that has come from the camp. The Pearl Lake Company has been making an examination of its property by diamond drilling, and in several sections has encountered high values.

The despatch received yesterday was to the effect that in No. 3 hole at a depth of 1,164 feet, two feet of core assayed $6, while one foot at 1,168 feet, assayed $9. At 1,180 feet the core was still in mineralized schist.

The drilling is being continued and further developments are being awaited with the greatest interest.

Elk Lake, Dec. 4.—Another shipping mine is added to the list in this district, the Canadian-Gowganda, having let the contract for hauling a 50,000-pound car of high-grade silver ore from the mine to the T. & N. O. at Charlton. The car now being shipped was stoped out of the drifts in about four weeks by a small gang of men.

ALBERTA.

Lethbridge, Nov. 24.—To-night the price of coal for the coming winter will be fixed. This morning's train from the west brought Lewis Stockett, president of the Western Coal Operators' Association; J. K. Gram, of Coleman, Alta; William Whiteside, of Blairmore, Alta.; W. G. Smith, of Corbin; W. W. Wilson, of Fernie, and William Lloyd, of Frank, all in charge of mines at these points. They are meeting in the offices of the Alberta Railway & Irrigation Co., and P. L. Naismith, and they will finish the business of the association regarding the strike and recent decisions which will guide their transactions as an association in future.

BRITISH COLUMBIA.

Vancouver, Dec. 4.—A special from Merritt, B.C., says three men were killed in a chute of No. 7 level of No. 2 mine of the Nicola Valley Coal & Coke Co.'s Middlesboro properties on Sunday. They are Dusan Wurmirovitch, a Servian, aged 25; Robert Dishart, a Scotchman, aged 28; and Alex. Thompson, aged 17.

The accident occurred one hour after the second shift had started work. The bodies were found huddled around the fan. Thompson's work was turning the fan to force out the foul air. The men were driving a tunnel to make an air way. It is the first accident since Charles Graham was superintendent.

UNITED STATES.

New York.—The Yukon Gold Co. has declared a quarterly dividend of 7½ cents a share—equal to 1½ per cent. This is a reduction from 10c. a share, or 2 per cent., from the last previous dividend. The dividend is payable December 30. Books close December 12th, and remain closed until January 9th, to provide for the annual meeting, which comes on January 8th.

In connection with the reduction, President Samuel R. Guggenheim makes the following statement:

"At a meeting of the directors it was decided to declare the quarterly dividend at the rate of 7½c., instead of 10c. per share, which has been paid formerly; that is, the directors have decided to place the company for the present upon a 6 per cent. per annum basis, instead of 8 per cent."

"The extraordinarily dull season prevailing in different parts of the world also affected Alaska and Yukon Territories, curtailing the hydraulic operations. The two new steel dredges, which had been built upon the property this season, were not finished in time to be of much benefit. The final figures for the season's operations are not at hand, but the advance statements indicate a net operating profit of approximately $1,300,000, as against an estimated profit of $1,500,000, which, if realized, would have allowed the continuation of dividends at the 8 per cent. rate."

Knoxville, Tenn., Dec. 9.—A dust explosion imprisoned about 200 men in the coal mine of the Knoxville Iron Company, near Briceville, 34 miles north of Knoxville, at 7.30 o'clock. The explosion is about two miles from the entrance to the mines.

The Federal mine rescue crew has been summoned. It is not yet possible to ascertain the number killed, but it is feared the loss of life will be very heavy.

Cripple Creek, Colo., Dec. 2.—The gold output from the Cripple Creek district for the past month amounted to $1,356.966.50, with a gross tonnage of 77,204. This is a decrease of 513 tons, and an increase of about $54,062 over the month of October. During the month the Homestake, Jo Dandy, and Isabella, low-grade mills of the camp, were closed down for divers reasons.

Leadville, Colo., Dec. 1.—The close of the eleventh month of the year finds the district in first class condition. With more work going on than for several years at the same period, more prospecting being done for new ore bodies and extensions of old ones, and during the period more shafts have been sunk and more tunnels driven throughout the district than has taken place in a number of years.

Los Angeles, Cal., Nov. 29.—October production, 7,283,434 barrels. Such is the official announcement of the yield of the California oil fields for the past month. During the same period the consumption totalled 6,701,693 barrels, leaving a net daily surplus of 18,765 barrels.

STATISTICS AND RETURNS

LE ROI NO. 2.

The following cable has been received at the London office of the Le Roi No. 2, Ltd., company from the managers in Rossland:

"Josie mine report for October—Shipped 1,590 tons of ore and 146 tons of concentrates. Receipts from smelter are $37,138 for 1,621 tons of ore shipped; $4,126 for 181 tons of concentrates shipped. In all $41,264.

"Estimated costs for corresponding period: Development, $9,000; ore production, $10,000; milling, $1,250; total, $20,250.

"North Annie, west drift, 500 feet level: Advancement, 43 feet; vein lost west of fault.

"Diamond Drill, 700 foot level—Struck one and one-half feet of ore, continuation recent North Annie ore chute."

NIPISSING IN NOVEMBER.

In the month of November the Nipissing produced net $225,907, and shipped $248,980, of which $90,407 was mine ore, and

$158,573 bullion, from the high grade mill. The October production was $226,929, shipments $225,282. November thus showed a decrease of $1,022 in production aud an increase of $23,698 in the ore shipped.

N. S. STEEL AND COAL.

Outputs from all departmeuts of the Nova Scotia Steel & Coal Company for November were very satisfactory, and in several instances new records were established. The month was particularly good at the New Glasgow works, every department there surpassing its best previous output.

In detail the outputs were: Coal mined, Nov., 77,587; Oct., 75,521; pig iron made, Nov., 7,170; Oct., 7,258; steel ingots, Nov., 7,423; Oct., 5,453; billets cogged, Nov., 7,694; Oct., 6,456; bars and plate rolled, Nov., 5,702; Oct., 4,817.

DOMINION STEEL.

The production of the Dominion Steel Company in November was very satisfactory. Rods, especially, loomed up, the mill turning out 8,325 tons, the best production since the bounty was taken off. The month's figures are as follows:

Pig iron	22,916
Steel ingots	27,084
Blooms	23,633
Rails	7,527
Rods	8,325
Shipments	19,923

LA ROSE PROFITS.

Operating profits of La Rose Consolidated Mines Company in October are reported as $75,561, bringing the operating profits for 10 months of 1911 to $995,158, an average of practically $100,000 a month. September profits were $94,779, and August $84,561.

Production in October was $255,802 ounces of silver, having a gross value of $136,045. Other income brought the total up to $141,306. Expenses amouuted to $65,744, leaving the operating profits $75,561. From Jan. 1 to Oct. 31, La Rose produced 3,011,583 ounces, valued at $1,585,494. Income from other sources was $14,623. Expenses were $604,959, leaving the operatiug profit for the 10 months $995,158.

COBALT ORE SHIPMENTS.

The following are the shipmeuts for the week ended Dec. 2nd in pounds:

Cobalt Lake, 2 1 1 h	210,600
Nipissing, 3 1	192,937
Kerr Lake, 1 h, 1 1	121,490

Engineers Locating Transit or

Light Mountain Transit

Achromatic Terrestrial Telescope, 9 inches; objective glass, 1⅛ inches aperture, with dust cap, sunshade and dust protector to object slide. Improved achromatic eye piece with spiral motion for focussing cross hairs. Stadia Wires. Graduated Level Vial to Telescope. Clamp and Tangent screw to Telescope with counter spring. Vertical circle 4½″ graduated to half degrees and numbered in quadrants, Vernier reading to one minute. Compass Needle, 3-1-8″ long. The compass is provided with variation plate, set by Capstan head pinion. Horizontal limb, 5-1-8″ graduated to half degrees and reading to one minute by two opposite Verniers placed at an angle of 30° to line of sight. The graduation has two rows of figures reading in opposite directions from Zero to 360°. Two Spirit Levels to horizontal limb, graduated on the glass, Clamp and Tangent screw with opposing spring. Long independent centre, four leveling screws, ⅝″ shifting centre. Weight of instrument without Tripod 9½ lbs.

Instrument complete in Mahogany finished box, with plumb bob reading glass, adjusting pins, etc. Extension tripod. **$157.50**

A Man's Value

to his family or those dependent upon him is measured by his earning capacity. As death entails the loss of that earning capacity, every man should make provision for his loved ones in order to make good to them the financial loss that would ensue. This is the purpose of life insurance, and no man is blameless whose life is not insured.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

DEPARTMENT OF MINES. GEOLOGICAL SURVEY.

PUBLICATIONS

The Geological Survey has published maps and reports dealing with a large part of Canada, with many local areas and special subjects.

A catalogue of publications will be sent free to any applicant. A single copy of a map or report that is specially desired will be sent to a Canadian applicant free of cost and to others at a nominal price. The applicant should state definitely the precise area concerning which information is desired, and it is often of assistance in filling an order for a map or report if he states the use for which it is required.

Most of the older reports are out of print, but they may usually be found in public libraries, libraries of the Canadian Mining Institute, etc.

REPORTS RECENTLY ISSUED:

CANADA

1085. Descriptive Sketch of the Geology and Economic Minerals of Canada. Accompanied by a geological and mineral map of Canada, by G. A. Young and R. W. Brock.

NEW BRUNSWICK and NOVA SCOTIA

1113. Memoir No. 16. The Clay and Shale Deposits of Nova Scotia and portions of New Brunswick, by H. Ries and J. Keele.

QUEBEC

1110. Memoir No. 4. Geological reconnaissance along the line of the National Transcontinental Railway in Western Quebec, by W. J. Wilson, accompanied by a map.

1064. Geology of an area adjoining the east side of Lake Timiskaming, by Morley E. Wilson.

ONTARIO

1137. Memoir No. 10. An instrumental survey of the shore-lines of the extinct lakes Algonquin and Nipissing in South-western Ontario, by J. W. Goldthwaite.

NORTH WEST PROVINCES

1115. Memoir No. 8. The Edmonton Coal Field, Alberta, with maps, by D. B. Dowling.

BRITISH COLUMBIA

1139. Memoir 11-T Triangulation and Spirit Levelling of Vancouver Island, 1909, by R. H. Chapman.

YUKON and NORTH WEST TERRITORIES

1080. Report on a part of the North West Territories drained by the Winisk and Attawapiskat Rivers, by Wm. McInnes.

1130. Memoir No. 9. Bighorn Coal Basin, Alberta, by G. S. Malloch, accompanied by a map.

YUKON and NORTH WEST TERRITORIES

1089. Map 9A. Explored Routes on Parts of the Albany, Severn and Winisk Rivers. Scale 8 miles to 1 inch.

NOTE.—Maps published within the last two years may be had, printed on linen for field use. A charge of 10 cents is made for maps on linen.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon. Letters and samples that are of a Departmental nature, addressed to the Director may be mailed O.H.M.S. free of postage.

Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.

BRITISH COLUMBIA

The Mineral Province of Western Canada

Has produced Minerals valued as follows: Placer Gold, $71,213,103; Lode Gold, $60,811,067; Silver, $31,095,602; Lead, $24,645,605; Copper, $60,743,405; Other Metals (Iron, Zinc, etc.), $1,083,172; Coal and Coke, $114,012,596: Building Stone, Brick, etc., $10,593,100; making its Mineral Production at the end of 1910 show an

Aggregate Value of $374,197,650.

In 1910 the quantity of Ore mined was 2,216,428 tons, and of coal 3,139,235 long tons. The value of Minerals produced that year was: Placer Gold, $540,000; Lode Gold, $5,533,386; Silver, $1,245,016; Lead, $1,386,350; copper, $4,871,512; Coal and Coke, $11,108,335; Other Minerals, $1,692,473, making the

Total Value for 1910, $26,377,066.

Lode-mining has only been in progress for about eighteen years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those in any other Province in the Dominion, or any Colony in the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with mining Reports and Maps, may be obtained gratis by addressing

THE HON. THE MINISTER OF MINES
VICTORIA, B. C.

The MCKIERNAN-TERRY CLASS "B" HAMMER DRILL

"Three "Busy Bees" at work on the New York Subway Excavation."

Are you sinking a shaft?
Would you like to do it cheaper and faster?

If so, follow the method used by the contractors in New York, who are putting down the big shafts for the Subway Excavations.
They are using "24 McKiernan Terry Class "B" Hammer Drills"
They call them "BUSY BEES."
These Drills will put down 8 ft. holes, either *wet or dry.*
They will bore about twice as fast as the reciprocating rock drill.
They use half as much air.
They require no setting up.
There is no time wasted.
They are BUSY all the time.
They are the last word in a shaft sinking tool.
BUY ONE AND TRY IT.

Province of Quebec

Department of Colonization, Mines, and Fisheries.

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, Etc.

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

MINERS' CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10.00 and it is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $10 an acre for SUPERIOR METALS when more than 20 miles distant from a railway and $20 an acre when less than 20 miles.

For INFERIOR METALS the prices are $2.00 and $4.00 an acre respectively.

The attention of prospectors is specially called to the territory in the North-Western part of the province of Quebec, north of the height of land, where important mineralized belts are known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, MONTREAL, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The Bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

THE HONORABLE THE MINISTER OF COLONIZATION, MINES, AND FISHERIES, QUEBEC.

Nova Scotia Mines

Gold, Coal, Iron, Copper, Lead, Tin, Manganese, Tungsten, and other minerals.

The Gold District covers more than three thousand square miles. Millions of dollars worth of gold have been taken from the gold fields of Nova Scotia and millions of dollar's worth remain for recovery.

Gold mining in this Province offers good inducement for investment. Labor is cheap and plentiful; timber and fuel are abundant.

Large deposits of iron also are known to exist at various places in the Province; and considerable mining has been done in connection with this mineral, the ore being used locally and shipped to foreign ports.

Among the most important minerals occurring in economic quantities may be mentioned, Coal, Gold, Silver, Manganese, Leadsilver, Copper, Barytes, Mineral Pigments, Gypsum and Tungsten.

Licenses are issued for prospecting for Gold and Silver for a term of twelve months. The licenses are for areas 150 by 250 feet, and can be obtained for 50c. an area.

Leases can be secured for $2. an area, for a term of forty years; subject to annual rental of 50c. an area.

Licenses to search over five square miles, for a period of eighteen months, for minerals other than gold and silver, cost $30.

Leases for three renewable terms of twenty years each can be obtained for $50., and are subject to a yearly rental of $30.

Royalties are as follows:—

Gold, two per cent on the gross value thereof; Copper, four cents a unit; Lead, two cents a unit; Iron, five cents a ton; Tin and Precious Stones, five per cent; Coal, ten cents on every long ton sold or removed from the mine.

Copies of the mining law can be had gratis, by applying to the Department of Public Works and Mines, Halifax, Nova Scotia, or to Mr. John Howard, Agent General for Nova Scotia, 57a Pall Mall, London, England.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. W. H. HEARST,
Minister of Lands, Forests and Mines,
Toronto, Canada.

THE "ROYAL LINE"

To Europe in

Less than Four Days

LAND TO LAND

The St. Lawrence Route to Europe by the ROYAL LINE shortens the ocean voyage to less than four days, and affords the traveller two days of delightful, sheltered sailing down the great St. Lawrence with its never ending panorama of beautiful scenery and historically famous points. The splendid triple turbine steamers

ROYAL GEORGE and ROYAL EDWARD

hold all speed records and afford the most luxurious accommodation in the Canadian-European service. The English Port, Bristol, is only two hour's run to London by the special boat trains which meet the Royal Line Steamers on arrival.

For further information see nearest Steamship Agent, or the Canadian Northern Steamships Limited.

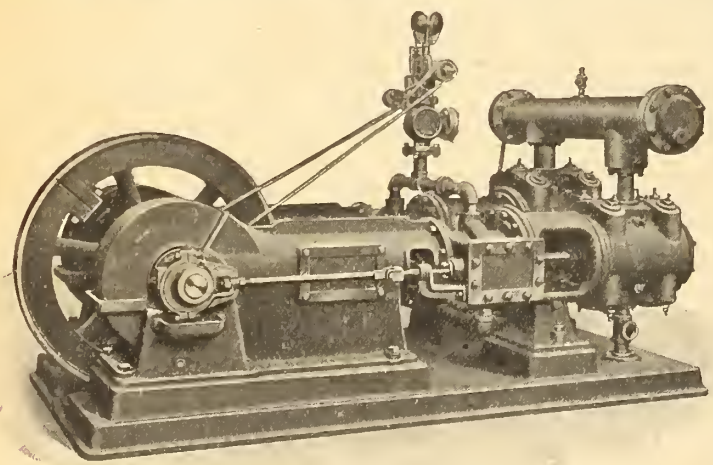
Laidlaw-Dunn-Gordon and Clayton
AIR COMPRESSORS



DUPLEX TWO STAGE ENCLOSED FORKFRAME

Extract from Letter Dated Nov. 29, 1911.

"I have one of the Laidlaw-Dunn-Gordon Air Compressors, manufactured by the Clayton Works, which is giving the best of satisfaction. I consider it one of the finest makes of air compressors on the market."

Signed

ORE DRESSING

The School of Mining, Kingston, Ont., is prepared to make mill runs on **GOLD ORES** in lots of from 2 to 20 tons to determine average value, percentage of free milling gold and to recommend the best method of treatment,

Also **CONCENTRATION TESTS, ORE SAMPLING, and ASSAYING.**

Terms on application to

GEO. Y. CHOWN

Secretary of School of Mining

KINGSTON, ONT.

MINING AND SCIENTIFIC PRESS

Controlled by T. A. Rickard — **Established 1860** — **H. Foster Bain, Editor** — **Published weekly** — **Thomas T. Read, Associate Editor**

In every issue valuable articles are published on mining, metallurgy, and geology, the latest news from special correspondents at the principal mining centers, letters giving the ideas and experience of successful men, and other items of useful knowledge.

THE MINING MAGAZINE

Established September, 1909

T. A. RICKARD, Editor — **Published monthly at London, England**

A monthly magazine is the natural corollary of a technical weekly. It permits of more deliberate and more extended notice of matters concerning which the news element is less important.

The Mining Magazine includes a review of the world's progress in mining, metallurgy, and economic geology, written by men who have personal knowledge of the regions and conditions discussed.
